200 MHz-Band Broadband Wireless Communication Systems between Portable BS and MSs

ARIB STANDARD

ARIB STD-T103 Version 1.0

Version 1.0  March 28th  2011

Association of Radio Industries and Businesses
General Notes to the English translation of ARIB Standards and Technical Reports

1. The copyright of this document is ascribed to the Association of Radio Industries and Businesses (ARIB).
2. All rights reserved. No part of this document may be reproduced, stored in a retrieval system, or transmitted, in any form or by any means, without the prior written permission of ARIB.
3. The establishment, revision and abolishment of ARIB Standards and Technical Reports are approved at the ARIB Standard Assembly, which meets several times a year. Approved ARIB Standards and Technical Reports are made publicly available in hard copy, CDs or through web posting, generally in about one month after the date of approval. This document may have been further revised therefore users are encouraged to check the latest version at an appropriate page under the following URL: http://www.arib.or.jp/english/index.html
4. The note about IPR (Industrial Property Rights) of the standard applies to the use of Essential IPR for the ARIB Standard in Japan. If the ARIB Standard is adopted outside Japan, Essential IPR will be treated in accordance with policies stated by each IPR owner. The IPR owners are, however, expected to apply the rules of the preface of the "Guidelines for Treatment of Industrial Property Rights in connection with the ARIB standard" (September 5, 1995, approved by the 1st Standard Assembly Meeting). In the preface of the Guidelines, it is stated that it is "desirable that the Essential IPR which relates to any or all parts of the contents of the ARIB Standards should be used free of charge by anyone and that it would not block the uses of such Essential IPR in any other country where such an ARIB Standard is adopted"
Introduction

Association of Radio Industries and Businesses (hereinafter ARIB) investigates and summarizes the basic technical requirements for various radio systems in the form of “technical standard (ARIB STD)”. These standards are being developed with the participation of, and through discussions amongst various radio equipment manufacturers and users.

ARIB standards include “government technical standards” (mandatory standards) that are set for the purpose of encouraging effective use of frequency resources and preventing interference, and “private technical standards” (voluntary standards) that are defined in order to guarantee compatibility between radio facilities, to secure adequate transmission quality as well as to offer greater convenience to radio equipment manufacturers and users, etc.

An ARIB STANDARD herein is published as “200 MHz-band Broadband Wireless Communication Systems between Portable Base Station and Mobile Stations”. In order to ensure fairness and transparency in the defining stage, the standard was set by consensus of the standard council with participation of interested parties including radio equipment manufacturers, telecommunication operators, broadcasters, testing organizations, general users, etc. with impartiality.

This standard is the adoption of IEEE Std 802.16-2009, “IEEE Standard for Local and metropolitan area networks – Part 16: Air Interface for Broadband Wireless Access Systems and consists of two modes, Mode 1 and Mode 2. Mode 1 and Mode 2 are based on IEEE Std 802.16-2009 PHY and MAC specifications. Mode 1 is compliant with “WirelessMAN-OFDMA” in IEEE Std 802.16-2009, which provides two sets of parameter choice for FFT size, 512 and 1024. In Mode 2, on the other hand, some parameters are modified from Mode 1 to cover country-specific issues, commonly known as national deviations (“National Deviations”), that is the operational frequency band (200 MHz band) allocated in Japan. In order to cover the “National Deviations” above, pilot subcarriers patterns for channel estimation and the related items are modified in Mode 2. The modified sections due to the “National Deviations” are Sections 4.6.1.2.2, 4.6.2.1.2, 4.6.2.2.2, 4.6.2.3.2, 4.9, 4.10.3.2 and 4.16.2 as described in the column of Mode 2 in the Table of Attachment 1. IEEE Std 802.16-2009, “IEEE Standard for Local and metropolitan area networks Part 16: Air Interface for Broadband Wireless Access Systems”, that this standard adopts, is attached.
ARIB STD·T103

ARIB sincerely hopes that this standard be utilized actively by radio equipment manufacturers and users, etc.

INDUSTRIAL PROPERTY RIGHTS (IPRs)

Although this ARIB Standard contains no specific reference to any Essential Industrial Property Rights relating thereto, the holders of such Essential Industrial Property Rights state to the effect that the rights listed in Attachment 1 and 2, which are the Industrial Property Rights relating to this standard, are held by the parties also listed therein, and that to the users of this standard, in the case of Attachment 1 (selection of option 1), such holders shall not assert any rights and shall unconditionally grant a license to practice such Industrial Property Rights contained therein, and in the case of Attachment 2 (selection of option 2), the holders shall grant, under the reasonable terms and conditions, a non-exclusive and non-discriminatory license to practice the Industrial Property Rights contained therein. However, this does not apply to anyone who uses this ARIB Standard and also owns and lays claim to any other Essential Industrial Property Rights of which is covered in whole or part in the contents of provisions of this ARIB Standard.

List of Essential Industrial Property Rights (IPRs)

The lists of Essential Industrial Property Rights (IPRs) are shown in the following Lists.

<table>
<thead>
<tr>
<th>Patent Holder</th>
<th>Name of Patent</th>
<th>Registration No. / Application No.</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>富士通株式会社</td>
<td>ARIB STD-T103 Ver1.0 について包括確認書を提出</td>
<td></td>

</tr>
</tbody>
</table>

*: These patents are applied to the part defined by ARIB STD-T103 Ver. 1.0.

Reference

This is the list of Essential Industrial Property Rights (IPRs) filed or applied to countries other than Japan. These are listed here as a reference, as the companies voluntarily informed ARIB of these IPRs.
Contents

Introduction

Chapter 1 General Descriptions.......................................................................................................1

1.1 Outline .....................................................................................................................................1
1.2 Scope of the Standard .................................................................................................................1
1.3 Normative References ..............................................................................................................3

Chapter 2 General System Outline .................................................................................................5

2.1 System Overview .....................................................................................................................5
2.2 System Configuration .............................................................................................................5

Chapter 3 General requirements and technical requirements for radio equipment ...............7

3.1 General Requirements ...........................................................................................................7

3.1.1 Communication method (Article 49.31 of [1]) .................................................................7
3.1.2 Frequency band (Article 49.31 of [1]) ................................................................................7
3.1.3 Multiplexing method (Article 49.31 of [1]) .........................................................................7
  3.1.3.1 Uplink (The radio transmission from the MS to the Portable BS) .........................7
  3.1.3.2 Downlink (The radio transmission from Portable BS to the MS) .........................7
3.1.4 Modulation (Article 49.31 of [1]) ....................................................................................7
  3.1.4.1 Uplink ....................................................................................................................7
  3.1.4.2 Downlink ..............................................................................................................7
3.1.5 Authentication, encryption, information security measure.............................................7
3.1.6 Electro-Magnetic Compatibility and Protection .................................................................8
3.1.7 Compliance to the radio protection policy .................................................................8
3.1.8 Mobile Identification Number .......................................................................................8
3.1.9 Malfunctioning Mobile Station to abort radio transmission ........................................8
3.1.10 Data transmission speed(Article 49.31 of [1]) .............................................................8

3.2 Technical requirements for radio equipment ........................................................................8

3.2.1 Transmitter requirements .................................................................................................8
  3.2.1.1 Frequency tolerance (Article 5 of [1]) .....................................................................8
  3.2.1.2 Occupied bandwidth (Article 6 of [1]) ....................................................................8
  3.2.1.3 Output power (Article 49.31 of [1]) .......................................................................8
  3.2.1.4 Output power tolerance (Article 14 of [1]) ..........................................................9
3.2.1.5 Adjacent channel leakage power (Article 49.31 of [1]) ..................................................9
3.2.1.6 Spurious emission (NT No.307, 2010) ........................................................................9
3.2.1.7 Antenna gain (Article 49.31 of [1]) .........................................................................10
3.2.1.8 Others ..................................................................................................................10
3.2.2 Receiver requirements ................................................................................................10

Chapter 4 Communication control method for PHY..........................................................11

4.1 Introduction ................................................................................................................11
4.2 OFDMA symbol description, symbol parameters and transmitted signal ...............11
4.2.1 Time domain description .........................................................................................11
4.2.2 Frequency domain description .............................................................................11
4.2.3 Primitive parameters ............................................................................................11
4.2.4 Derived parameters ...............................................................................................11
4.2.5 Transmitted signal .................................................................................................12
4.3 OFDMA basic terms definition ..................................................................................12
4.3.1 Slot and data region ...............................................................................................12
4.3.2 Segment ................................................................................................................12
4.3.3 Permutation zone ....................................................................................................12
4.3.4 OFDMA data mapping ..........................................................................................12
4.4 Frame structure .........................................................................................................12
4.4.1 TDD frame structure ..............................................................................................12
4.4.2 OFDMA Frame Parameters and Operations ..........................................................12
4.4.3 DL frame prefix ......................................................................................................12
4.4.4 Allocation of subchannels for FCH and DL-NK, and logical subchannel numbering .........................................................................................................................13
4.4.5 DL transmission allocations ..................................................................................13
4.5 Map message fields and IEs .......................................................................................13
4.5.1 DL-NK PHY Synchronization field .........................................................................13
4.5.2 Frame duration codes .............................................................................................13
4.5.3 DL-NK IE format .....................................................................................................13
4.5.3.1 DIUC allocation ..................................................................................................13
4.5.3.2 HARQ and Sub-MAP Pointer IE (Optional) .......................................................13
4.5.3.3 HARQ DL MAP IE (Optional) ..........................................................................13
4.5.3.4 DL HARQ ACK IE (Optional) ..........................................................................13

4.5.4 UL-MAP IE format .....................................................................................................13
  4.5.4.1 UIUC allocation ...................................................................................................14
  4.5.4.2 CDMA Allocation UL-MAP IE format .................................................................14
  4.5.4.3 HARQ UL-MAP IE (Optional) ...........................................................................14
  4.5.4.4 HARQ ACK Region Allocation IE (Optional) ....................................................14
4.5.5 Burst profile format .................................................................................................14
4.5.6 Compressed maps ....................................................................................................14
  4.5.6.1 Compressed DL-MAP........................................................................................14
  4.5.6.2 Compressed UL-MAP ........................................................................................14
4.6 OFDMA subcarrier allocations ....................................................................................14
  4.6.1 Downlink (DL) .......................................................................................................14
    4.6.1.1 Preamble ..........................................................................................................14
      4.6.1.1.1 Common SYNC symbol sequence..........................................................15
    4.6.1.2 Symbol structure .............................................................................................15
      4.6.1.2.1 Mode1 ........................................................................................................15
      4.6.1.2.2 Mode2 ........................................................................................................15
  4.6.2 Uplink (UL) ............................................................................................................15
    4.6.2.1 Symbol structure for subchannel.................................................................16
      4.6.2.1.1 Mode1 ........................................................................................................16
      4.6.2.1.2 Mode2 ........................................................................................................16
    4.6.2.2 Partitioning of subcarriers into subchannels in the UL.............................17
      4.6.2.2.1 Mode 1 ....................................................................................................17
      4.6.2.2.2 Mode 2 ....................................................................................................17
    4.6.2.3 UL permutation example .............................................................................19
      4.6.2.3.1 Mode 1 ....................................................................................................19
      4.6.2.3.2 Mode 2 ....................................................................................................19
    4.6.2.4 Data subchannel rotation scheme ..........................................................20
  4.7 OFDMA ranging ..........................................................................................................20
  4.7.1 Initial ranging ......................................................................................................20
  4.7.2 Periodic ranging and BR transmissions .........................................................20
  4.7.3 Ranging codes ...................................................................................................20
  4.7.4 Ranging and BR opportunity size ...................................................................20
4.8 Space-time coding (STC) (optional in Mode 1) .........................................................20
  4.8.1 STC using two antennas ...................................................................................20
4.9 Transmit Diversity Schemes (optional in Mode 2) ....................................................20
4.9.1 Closed-Loop Transmit Diversity using two antennas ...............................................20
  4.9.1.1 Interference Assisted Scheme (IAS) .................................................................20
    4.9.1.1.1 Array Gain Maximization Block .................................................................22
    4.9.1.1.2 IAS Transmitter .........................................................................................23
    4.9.1.1.3 Combiner Block .........................................................................................23
  4.9.1.2 Closed-Loop Transmit Diversity using four antennas ........................................24
    4.9.1.2.1 Interference Assisted Scheme (IAS) .............................................................24
    4.9.1.2.1.1 Array Gain Maximization Block ...............................................................24
    4.9.1.2.1.2 IAS Transmitter ......................................................................................25
    4.9.1.2.1.3 Combiner Block ......................................................................................25
  4.9.3 IAS with Maximum Ratio Combining (MRC) ......................................................29
  4.9.4 Relevant changes .................................................................................................31

4.10 Channel coding ........................................................................................................33
  4.10.1 Randomization ..................................................................................................33
  4.10.2 Encoding ..........................................................................................................33
    4.10.2.1 Convolutional coding (CC) .........................................................................33
    4.10.2.2 Convolutional turbo codes (CTCs) (optional) ..............................................33
  4.10.3 Interleaving ......................................................................................................33
    4.10.3.1 Mode 1 ........................................................................................................33
    4.10.3.2 Mode 2 ........................................................................................................33
  4.10.4 Modulation ......................................................................................................33
    4.10.4.1 Subcarrier randomization ...........................................................................33
    4.10.4.2 Data modulation .........................................................................................33
    4.10.4.3 Pilot modulation .........................................................................................33
    4.10.4.4 Example of OFDMA UL CC encoding .......................................................34
  4.10.5 Repetition ........................................................................................................34
  4.10.6 Zone boosting ..................................................................................................34

Attachment 4 IEEE standard for Local and metropolitan area networks
Chapter 1 General Descriptions

1.1 Outline

This ARIB STANDARD (hereinafter “this standard”) specifies the physical (PHY) layer and the media access control (MAC) layer of the radio equipment of “portable” base stations and mobile stations for the broadband wireless communication systems using 200 MHz band stipulated in the Ministry of Internal Affair and Communications (MIC) Ordinance Regulating Radio Equipment (ORE), Article 49.31. This standard consists of two modes, Mode 1 and Mode 2. Table 1-1 compares major parameters of these two modes. Mode 1 is the subset of “WirelessMAN-OFDMA” in the IEEE802.16™ standard, which provides two sets of parameter choice for FFT size, 512 and 1024. In Mode 2, on the other hand, some parameters are modified from Mode 1 to fit the broadband communication operation in the allocated frequency band (200 MHz band). Main difference between Mode 1 and Mode 2 is the FFT size and the pilot subcarriers patterns for channel estimation. FFT size is 512 or 1024 in Mode 1 and 1024 only in Mode 2. Regarding the pilot subcarriers pattern, the time interval between the pilot subcarriers in one radio resource unit (“tile” in the WirelessMAN-OFDMA) is longer in Mode 2 compared with Mode 1.

Organization of this standard is as follows. Chapter 2 describes the system overview. Chapter 3 describes the general technical requirements of the radio facilities. Chapter 4 specifies technical requirements of physical (PHY) layer of the system. Chapter 5 specifies technical requirements of media access control (MAC) layer of the system. Chapter 6 describes measurement method of the equipment. Chapter 7 summarizes terms and abbreviations used in this standard.

In Chapter 4 (PHY) and Chapter 5 (MAC), specifications of Mode 1 and Mode 2 are separately described in each subsection only when there exist differences between Mode 1 and Mode 2.

1.2 Scope of the Standard

MIC ORE, Article 49.31[1] describes the Japanese 200 MHz-band broadband wireless communication systems, which includes several possible operation forms as shown in Figure 1-1. This standard deals with only form (b) consisting of portable BS and MSs. Figure 1-2 shows the scope of this standard. Specifications of PHY and MAC layers of this system are described in this standard. This system does not cover the features of AAS, MIMO, mini-subchannel, etc that may be supported by the form (a) that is so-called “large-zone system”.
Table 1-1 Classification of the specifications in this standard

Chapter 2  General System Outline

2.1  System Overview

This section describes overview of the wireless communication system specified in this standard. As described in Section 1.2, this document covers specifications of Physical layer (PHY) and MAC layer of the Japan 200 MHz-band broadband wireless communication systems between portable base station (BS) and mobile station (MS). Portable BS is a mobile station of the Radio Law, therefore it can be carried to necessary place and set up flexibly. Mobile station is set up near the disaster area, accidental area etc. and video image of the scene can be transmitted from the MS to the Portable BS in real time. This enables appropriate assessment of the situation and results in precise instructions.

Communication/duplex scheme of the system is OFDMA/TDD with the occupied bandwidth of 5 MHz per channel. Basic concept of the system is shown in Fig.2.1-1. Figure 2.1-1 shows one example of the situations that two MSs are communicating the Portable BS by OFDMA/TDD scheme. As shown at the top of Fig.2.1-1, radio resources (d1, d2) consisting of time domain and frequency domain are allocated to the two MSs.

![Diagram of 200 MHz-band broadband wireless communication system](image)

Figure2.1-1 Basic concept of 200 MHz-band broadband wireless communication system between Portable BS and MSs

2.2  System Configuration

The basic system consists of one portable BS and one or multiple MS(s). One set of the system is carried to the area where it is needed. In principle, portable BS is set on the top of building or on the roof-top of a car etc. and being operated without moving. MSs connected to video
camera(s) is(are) situated nearer the spot of disaster, accident etc. One BS and one or multiple MS(s) are communicating and the relevant scene taken by video camera is transmitted from MS(s) to the portable BS in real time.
Chapter 3  General requirements and technical requirements for radio equipment

This chapter provides the regulations and associated technical requirements regarding the radio equipment of the ARIB STD-T103 systems. The requirements are intended for the use in the Japanese 200 MHz band, which are provisions written in Japanese in the regulations in MIC ORE 49.31[1] and related Regulations, Notifications shown in the references [2]-[4] in Section 1.3. The original regulations in Japanese prevail if any ambiguity is found between the requirements in this chapter and the original regulations.

3.1  General Requirements
3.1.1  Communication method (Article 49.31 of [1])
      TDD (Time Division Duplex)

3.1.2  Frequency band (Article 49.31 of [1])
      170 MHz – 202.5 MHz

3.1.3  Multiplexing method (Article 49.31 of [1])
3.1.3.1  Uplink (The radio transmission from the MS to the Portable BS)
         OFDMA (Orthogonal Frequency Division Multiple Access)

3.1.3.2  Downlink (The radio transmission from Portable BS to the MS)
         Combination of OFDM (Orthogonal Frequency Division Multiplexing) and TDM (Time Division Multiplexing)

3.1.4  Modulation (Article 49.31 of [1])
3.1.4.1  Uplink
         QPSK, 16QAM, 64QAM

3.1.4.2  Downlink
         QPSK, 16QAM, 64QAM

3.1.5  Authentication, encryption, information security measure
      To prevent unauthorized use of the system, secured protection measures such as user identification by mobile equipment number, user authentication, transmission data encryption, shall be applied as needed.
3.1.6 Electro-Magnetic Compatibility and Protection

In order to mitigate electromagnetic interference between a mobile terminal and a car-mounted electronic device and/or a medical electronic device, adequate measures shall be taken in the equipment.

3.1.7 Compliance to the radio protection policy

The Access Terminal that utilizes radio waveform shall meet the Article 21.3 of [2].

3.1.8 Mobile Identification Number

It is desired that assignment of a mobile identification number and grant for protocol negotiation are determined with consideration of users' sufficient convenience such as flexible network selection, roaming availability, information security measure, radio Access Network policy, etc.

3.1.9 Malfunctioning Mobile Station to abort radio transmission

The system shall be able to apply the following measures independently:

As the base station detects malfunction of a mobile station, it shall be able to enforce the mobile station to abort transmitting radio signals.

As the mobile station detects its malfunction, it shall abort transmitting radio signals upon expiring of its malfunction detection timer.

3.1.10 Data transmission speed(Article 49.31 of [1])

Data transmission speed of the modulated signal shall be 500kbps or more.

3.2 Technical requirements for radio equipment

3.2.1 Transmitter requirements

3.2.1.1 Frequency tolerance (Article 5 of [1])

Less than or equal to $5 \times 10^{-6}$

3.2.1.2 Occupied bandwidth (Article 6 of [1])

Less than or equal to 4.9 MHz

3.2.1.3 Output power (Article 49.31 of [1])

Less than or equal to 5 W (37 dBm)
Note: According to ORE, Article 49.31, transmit power is up to 20 W for BS. However, this Standard deals with only the portable system, as described in Chapter 1, by using “portable” BS and MSs. Since portable BS is determined as MS in the Radio Law, the transmit power is limited up to 5 W in this system.

3.2.1.4 Output power tolerance (Article 14 of [1])
Not less than -50 % and not greater than +50 %

3.2.1.5 Adjacent channel leakage power (Article 49.31 of [1])
Less than or equal to -21dBc
(in 4.8 MHz band where 2.6-7.4 MHz offset from the center of the relevant channel)
Less than or equal to -41dBc
(in 4.8 MHz band where 7.6-12.4 MHz offset from the center of the relevant channel)

3.2.1.6 Spurious emission (NT No.307, 2010)

<table>

3.2.2.2 Others

Receiver sensitivity, Spurious response, Adjacent channel selectivity, Intermodulation selectivity should be taken into consideration.
Chapter 4  Communication control method for PHY

4.1 Introduction

In this Chapter, the PHY layer specification of the 200 MHz-band Wireless Broadband Communication System is described. As described in Chapter 1, this standard consists of two modes, Mode 1 and Mode 2. Since there are many common specifications between Mode 1 and Mode 2, specifications of Mode 1 and Mode 2 are separately described in each subsection in case that there exist differences between Mode 1 and Mode 2. Parameters used in the 200 MHz-band system are chosen from the parameter set of IEEE802.16-2009.

This chapter specifies the required parameters selected from the basement document of IEEE802.16-2009. Those sets include both the Mobile WiMAX [6] as is basis and a subset of IEEE802.16-2009 for Mode1, and Mode2. The parameters labeled with (optional) shows that is contained in WiMAX as mandatory. Attachment 1 lists those differences in the parameter sets among these three base systems.

Mode 1 based on at least one of the FFT sizes 1024 and 512, and Mode 2 based on the FFT size 1024 shall be supported for the channel bandwidth of 5 MHz.

4.2 OFDMA symbol description, symbol parameters and transmitted signal

4.2.1 Time domain description

Refer to “8.4.2.1 Time domain description” of [5].

4.2.2 Frequency domain description

Refer to “8.4.2.2 Frequency domain description” of [5].

4.2.3 Primitive parameters

The following four primitive parameters characterize the OFDMA symbol:
- BW: The nominal channel bandwidth (5 MHz).
- Nused: Number of used subcarriers (which includes the DC subcarrier).
- n: Sampling factor. ( n= 28/25).
- G: This is the ratio of CP time to “useful” time. The following values shall be supported: 1/32, 1/16, 1/8, and 1/4.

4.2.4 Derived parameters

Refer to “8.4.2.4 Derived parameters” of [5].
4.2.5 Transmitted signal
   Refer to “8.4.2.5 Transmitted signal” of [5].

4.3 OFDMA basic terms definition
4.3.1 Slot and data region
   Refer to “8.4.3.1 Slot and data region” of [5]. In this system, subcarrier allocation scheme of PUSC (defined later) is used for both UL and DL.

4.3.2 Segment
   Refer to “8.4.3.2 Segment” of [5].

4.3.3 Permutation zone
   Refer to “8.4.3.3 Permutation zone” of [5].

4.3.4 OFDMA data mapping
   Refer to “8.4.3.4 OFDMA data mapping” of [5].

4.4 Frame structure
   The duplex method shall be TDD as shown in Section 3.1.1.

4.4.1 TDD frame structure
   Refer to “8.4.4.1 TDD frame structure” of [5].

4.4.2 OFDMA Frame Parameters and Operations
   Refer to “8.4.4.3 OFDMA Frame Parameters and Operations” of [5]. In this system, subcarrier allocation scheme of PUSC (defined later) is used for both UL (the link from mobile station to portable base station) and DL (the link from portable base station to mobile station). Duplex method is TDD.

4.4.3 DL frame prefix
   Refer to “8.4.4.4 DL frame prefix” of [5]. In Table 314 in Section 8.4.4.4, DL frame prefix of CC encoding used on DL-MAP or CTC encoding used on DL-MAP are selected as “Coding Indication”. In Table 315 in the Section 8.4.4.4 of [5], 512 or 1024 is used as FFT size.
4.4.4 Allocation of subchannels for FCH and DL-MAP and logical subchannel numbering

Refer to “8.4.4.5 Allocation of subchannels for FCH and DL-MAP and logical subchannel numbering.

4.4.5 UL transmission allocations

Refer to “8.4.4.6 UL transmission allocations” of [5]. Duplex method is TDD.

4.5 Map message fields and IEs

4.5.1 DL-MAP PHY Synchronization field

Refer to “8.4.5.1 DL-MAP PHY Synchronization field” of [5].

4.5.2 Frame duration codes

Refer to “8.4.5.2 Frame duration codes” of [5].

4.5.3 DL-MAP IE format

Refer to “8.4.5.3 DL-MAP IE format” of [5].

4.5.3.1 DIUC allocation

Refer to “8.4.5.3.1 DIUC allocation” of [5].

4.5.3.2 HARQ and Sub-MAP Pointer IE (Optional)

Refer to “8.4.5.3.10 HARQ and Sub-MAP Pointer IE” of [5].

4.5.3.3 HARQ DL MAP IE (Optional)

Refer to “8.4.5.3.21 HARQ DL MAP IE” of [5].

4.5.3.4 DL HARQ ACK IE (Optional)

Refer to “8.4.5.3.22 DL HARQ ACK IE” of [5].

4.5.4 UL-MAP IE format

Refer to “8.4.5.4 UL-MAP IE format” of [5].
4.5.4.1 UIUC allocation
   Refer to “8.4.5.4.1 UIUC allocation” of [5].

4.5.4.2 CDMA Allocation UL-MAP IE format
   Refer to “8.4.5.4.3 CDMA Allocation UL-MAP IE format” of [5].

4.5.4.3 HARQ UL-MAP IE (Optional)
   Refer to “8.4.5.4.22 HARQ UL-MAP IE” of [5].

4.5.4.4 HARQ ACK Region Allocation IE (Optional)
   Refer to “8.4.5.4.23 HARQ ACK Region Allocation IE” of [5].

4.5.5 Burst profile format
   Refer to “8.4.5.5 Burst profile format” of [5].

4.5.6 Compressed maps
   Refer to “8.4.5.6 Compressed maps” of [5].

4.5.6.1 Compressed DL-MAP.
   Refer to “8.4.5.6.1 Compressed DL-MAP” of [5].

4.5.6.2 Compressed UL-MAP.
   Refer to “8.4.5.6.2 Compressed UL-MAP” of [5].

4.6 OFDMA subcarrier allocations
   Refer to “8.4.6 OFDMA subcarrier allocations” of [5]. In this system, sampling factor is 28/25 for the channel bandwidth of 5 MHz and also subcarrier allocation scheme of PUSC (defined in later) is used for both UL and DL

4.6.1 Downlink (DL)
   Refer to “8.4.6.1 Downlink (DL)” of [5].

4.6.1.1 Preamble
   Refer to “8.4.6.1.1 Preamble” of [5]. 512 or 1024 is used as FFT size.
4.6.1.1 Common SYNC symbol sequence

Refer to “ 8.4.6.1.1.2 Common SYNC symbol sequence” of [5].

4.6.1.2 Symbol structure
4.6.1.2.1 Mode1

Refer to “ 8.4.6.1.2.1 Symbol structure for PUSC” of [5].

4.6.1.2.2 Mode2

A slot in the DL of Mode 2 is composed of four (4) OFDMA symbols and one subchannel. Within each slot, there are 48 data subcarriers and 16 fixed-location pilots. The subchannel is constructed from four (4) DL tiles. Each tile has four successive active subcarriers, and its configuration is illustrated in Figure 4.6.1.2.2-1.

![Figure 4.6.1.2.2-1 Description of DL tile in Mode 2](image)

4.6.2 Uplink (UL)

For Mode 1, refer to “ 8.4.6.2 Uplink (UL)” of [5]. Optional PUSC permutation is excluded and FFT size is either 512 or 1024. Parameters for Mode2 are summarized in Table 4.6.2-1.
Table 4.6.2-1  1024-FFT OFDMA UL subcarriers allocations for Mode 2

4.6.2.1 Symbol structure for subchannel

4.6.2.1.1 Mode1

Refer to “8.4.6.2.1 Symbol structure for subchannel (PUSC)” of [5].

4.6.2.1.2 Mode2

A slot in the UL of Mode 2 is composed of seven (7) OFDMA symbols and one subchannel (two tiles). Within each slot, there are forty eight (48) data subcarriers and eight (8) fixed-location pilots. The subchannel is constructed from two UL tiles. Each tile has four successive active subcarriers, and its configuration is illustrated in Figure 4.6.2.1.2-1.
4.6.2.2 Partitioning of subcarriers into subchannels in the UL

4.6.2.2.1 Mode 1

Refer to “8.4.6.2.2 Partitioning of subcarriers into subchannels in the UL” of [5].

4.6.2.2.2 Mode 2

The usable subcarriers in the allocated frequency band shall be divided into $N_{tile}$ physical tiles with parameters specified by Table 4.6.2-1. The allocation of physical tiles to logical tiles in subchannels is performed in the following manner:

Logical tiles are mapped to physical tiles in the FFT using Equation 4.6.2.2.2-1.

$$Tiles(s, n) = N_{subchannels} \cdot n + (Pt[(s+n) \mod N_{subchannels}] + UL_{PermBase}) \mod N_{subchannels} \quad (Eq.4.6.2.2.2-1)$$

where

$Tiles(s, n)$ is the physical tile index in the FFT with tiles being ordered consecutively from the most negative to the most positive used subcarrier (0 is the starting tile index)

$n$ is the tile index 0,1 in a subchannel

$Pt$ is the tile permutation shown below

$Pt = \{3, 52, 35, 67, 94, 13, 80, 6, 34, 45, 43, 68, 84, 66, 7, 37, 71, 89, 55, 101, 27, 60, 51, 14, 21, 17, 93, 72, 95, 73, 81, 24, 103, 86, 39, 29, 56, 62, 70, 64, 23, 22, 54, 15, 90, 76, 100, 3, 36, 18, 9, 91, 19, 26, 12,\ldots\}$
After mapping the physical tiles in the FFT to logical tiles for each subchannel, the data subcarriers per slot are enumerated by the following process:

a) After allocating the pilot carriers within each tile, indexing of the data subcarriers within each slot is performed starting from the first symbol at the lowest indexed subcarrier of the lowest indexed tile, continuing in an ascending manner through the subcarriers in the same symbol, then going to the next symbol at the lowest indexed data subcarrier, and so on. Data subcarriers shall be indexed from 0 to 47.

b) The mapping of data onto the subcarriers shall follow Equation 4.6.2.2.2-2. This equation calculates the subcarrier index to which the data constellation point is to be mapped.

\[ \text{Subcarrier}(n, s) = (n + 13 \cdot s) \mod N_{\text{subcarriers}} \]  

(Eq.4.6.2.2.2-2)

where

- \( \text{Subcarrier}(n, s) \) is the permuted subcarrier index corresponding to data subcarrier
- \( n \) is a running index 0…47, indicating the data constellation point
- \( s \) is the subchannel number 0…104
- \( N_{\text{subcarriers}} \) is the number of subcarriers per slot: 48

For example, for subchannel 1 (\( s = 1 \)), the first data constellation point (\( n = 0 \)) is mapped onto \( \text{Subcarrier}(0, 1) = 13 \), where 13 is the subcarrier with index 13 according to step a) in this subclause. Considering the PUSC tile structure, it can be seen that this is the second indexed subcarrier on the third symbol within the slot. Similarly, for subchannel 3, the ninth data constellation point (\( n = 8 \)) is mapped onto \( \text{Subcarrier}(8, 3) = 47 \). According to step a), this is the last indexed subcarrier of the seventh symbol within the slot.

Subcarrier enumeration shall not be applied to the slots in the UL-MAP indicated by either UIUC = 0, UIUC = 11 (Extended-2 UIUC) with Type=8, UIUC = 12, or UIUC = 13.
4.6.2.3 UL permutation example

4.6.2.3.1 Mode 1

Refer to “8.4.6.2.3 UL permutation example” of [5].

4.6.2.3.2 Mode 2

To illustrate the use of the permutations, an example is provided to clarify the operation of the permutation formula, Equation 4.6.2.2.2-1.

The tiles used for subchannel \( s = 3 \) in \( \text{UL}_\text{PermBase} = 2 \) are computed for 1024 FFT size. The relevant parameters characterizing the UL are, therefore, taken from Table 4.6.2-1:

- Number of subchannels: \( N_{\text{subchannels}} = 105 \)
- Number of subcarriers in each OFDMA symbol = 8
- Number of data subcarriers in each slot: \( N_{\text{subcarriers}} = 48 \)
- Tile Permutation = \( \{3, 52, 35, 67, 94, 13, 80, 6, 34, 45, 43, 68, 84, 66, 7, 37, 71, 89, 55, 101, 27, 60, 51, 14, 21, 17, 93, 72, 95, 73, 81, 24, 103, 86, 39, 29, 56, 62, 70, 64, 23, 22, 54, 15, 90, 76, 100, 3, 36, 18, 9, 91, 19, 26, 12, 92, 48, 25, 87, 74, 5, 31, 85, 40, 104, 2, 102, 69, 57, 50, 1, 44, 0, 20, 88, 79, 16, 28, 46, 42, 41, 59, 96, 97, 99, 82, 30, 49, 65, 77, 63, 11, 8, 75, 98, 38, 32, 83, 4, 47, 58, 61, 78, 10, 53\} \)

Using Equation 4.6.2.2.2-1

The basic series of 105 numbers is \( \{3, 52, 35, 67, 94, 13, 80, 6, 34, 45, 43, 68, 84, 66, 7, 37, 71, 89, 55, 101, 27, 60, 51, 14, 21, 17, 93, 72, 95, 73, 81, 24, 103, 86, 39, 29, 56, 62, 70, 64, 23, 22, 54, 15, 90, 76, 100, 3, 36, 18, 9, 91, 19, 26, 12, 92, 48, 25, 87, 74, 5, 31, 85, 40, 104, 2, 102, 69, 57, 50, 1, 44, 0, 20, 88, 79, 16, 28, 46, 42, 41, 59, 96, 97, 99, 82, 30, 49, 65, 77, 63, 11, 8, 75, 98, 38, 32, 83, 4, 47, 58, 61, 78, 10, 53\} \).

Apply the permutation due to the selection of the subchannel \( (s) \), rotate three times:
\( \{78, 10, 53, 3, 52, 35, 67, 94, 13, 80, 6, 34, 45, 43, 68, 84, 66, 7, 37, 71, 89, 55, 101, 27, 60, 51, 14, 21, 17, 93, 72, 95, 73, 81, 24, 103, 86, 39, 29, 56, 62, 70, 64, 23, 22, 54, 15, 90, 76, 100, 3, 36, 18, 9, 91, 19, 26, 12, 92, 48, 25, 87, 74, 5, 31, 85, 40, 104, 2, 102, 69, 57, 50, 1, 44, 0, 20, 88, 79, 16, 28, 46, 42, 41, 59, 96, 97, 99, 82, 30, 49, 65, 77, 63, 11, 8, 75, 98, 38, 32, 83, 4, 47, 58, 61\} \).

Take the first 2 numbers, and add the UL_PermBase (perform modulo operation if needed): \( \{80, 12\} \).

Finally, add the appropriate shift: \( \{80, 47\} \).
4.6.2.4 Data subchannel rotation scheme

Refer to “8.4.6.2.6 Data subchannel rotation scheme” of [5]. Optional PUSC UL is not used.

4.7 OFDMA ranging

Refer to “8.4.7 OFDMA ranging” of [5].

4.7.1 Initial ranging

Refer to “8.4.7.1 Initial ranging and HO ranging transmissions” of [5]. HO ranging is not used.

4.7.2 Periodic ranging and BR transmissions

Refer to “8.4.7.2 Periodic ranging and BR transmissions” of [5].

4.7.3 Ranging codes

Refer to “8.4.7.3 Ranging codes” of [5].

4.7.4 Ranging and BR opportunity size

Refer to “8.4.7.4 Ranging and BR opportunity size” of [5].

4.8 Space-time coding (STC) (optional in Mode 1)

Refer to “8.4.8 Space-time coding (STC) (optional)” of [5].

4.8.1 STC using two antennas

Refer to “8.4.8.1 STC using two antennas” of [5].

4.9 Transmit Diversity Schemes (optional in Mode 2)

4.9.1 Closed-Loop Transmit Diversity using two antennas

4.9.1.1 Interference Assisted Scheme (IAS)

In the case Channel State Information (CSI) is available at the transmitter side, diversity improvement can be achieved, however, with the cost of feedback from receiver to transmitter. Full CSI at the transmitter requires very high amount of feedback, therefore, schemes taking advantage of limited CSI knowledge at the transmitter (few bits feedback) are preferable.

The following figure describes the structure of closed loop IAS based system with an array of 2 transmit antennas (n_t = 2).
The multiple-input-single-output (MISO) channel vector $\mathbf{H} = [h_1 \ h_2] \in \mathbb{C}^{1 \times nt}$ between the base station and the single antennae receiver (RX) device is considered to be either quasi-static with very low time selectivity, owing to the low Doppler spread inherent to the 200 MHz frequency band.

Upon the reception of Report Command parameter ‘Channel Type Request = 100’ (for 2 TX antennas) or ‘Channel Type Request = 101’ (for 4 TX antenna case) transmitted by TX, the RX is enabled to employ IAS.

For a system with 2 TX antennas, a total of two unique transmit vectors $G_m$, for $m \in \{0, 1\}$, with each $G_m$ yielding one single aligned array interference $I_{Am}$. It should be noted that $I_{Am}$ are functions of the fading channel $\mathbf{H}$, and consequently, can be calculated beforehand. Therefore, $I_{Am}$ can be stored in RX device memory.

After channel estimation is performed by the ‘channel estimator’ block, the ‘array gain maximization’ block compares the $I_{Am}$ and selects the one that has the maximum value,

$$\arg \max_m(I_{Am}), \forall m \in \{0, 1\}$$

(Eq.4.9.1.1-1)

Following, ‘the array gain maximization’ block feedbacks the index $m$, in binary to the TX through the “partial feedback channel” and also sends it to the ‘combiner’ block, which is collocated in the same RX device.

The following $G_m$ to be transmitted over the channel $\mathbf{H}$ will yield the maximum overall gain
(assuming $\mathbf{H}$ does not vary due to the low Doppler frequency of a 200MHz system). For instance, if the feed backed index $m$ from RX is ‘1’, the TX transmits $G_1$ since it assumes that this transmit vector produces the most aligned array interference while the ‘combiner’ block will utilize the weight $w_1$, when it receives the signal from TX.

Once communication starts with the decided transmit vector $G_m$, ‘channel estimator’ block provides the ‘combiner’ block with channel estimates and the later, after doing the proper signal manipulation (combination), provides symbol estimate to the ‘maximum likelihood (MML) detector’ block. The ‘array gain maximization’ block continues to search for the maximum aligned array interference $I_{Am}$ based on the channel estimates it receives constantly from ‘channel estimator’ block.

The channel $\mathbf{H}$ is calculated by using pilot subcarriers in IAS operation mode shown below.

**Figure 4.9.2.1-2  Cluster structure for 2 TX antennas in IAS mode (only for Mode 2)**

### 4.9.1.1.1 Array Gain Maximization Block

In the array gain maximization block, the array interference $I_{Am}$ is stored as a function of $\mathbf{H}$.

- **Array Interference $I_{A0}$**
  \[
  I_{A0} = h_1^* h_2 + h_1 h_2^*
  \]
  (Eq.4.9.1.1.1-1)

- **Array Interference $I_{A1}$**
  \[
  I_{A1} = -h_1^* h_2 - h_1 h_2^*
  \]
  (Eq.4.9.1.1.1-2)

In order to select the most aligned interference, the ‘array gain maximization’ block performs

\[
\arg \max_m (I_{Am}), \forall m \in \{0,1\}
\]

(Eq.4.9.1.1.1-3)

The index $m$ of the selected interference is feed backed through the ‘partial feedback channel’ to the transmitter (in 8bits) as well as to the ‘combiner block’, collocated in the same device.
4.9.1.1.2 IAS Transmitter

- Transmit $G_0 = [s\ s]$ if the feedback received through ‘partial feedback channel’ is ‘00000000’;
- Transmit $G_1 = [s\ -s]$ if the feedback received through ‘partial feedback channel’ is ‘00000001’;

4.9.1.1.3 Combiner Block

Let $H = [h_1\ h_2]$ and $^T$ denotes transpose operation and $n$, the zero-mean additive white Gaussian noise (AWGN).
- If the ‘combiner’ block receives $m = 0$ from the ‘array gain maximization’ block, the received signal is
  
  $$y = G_0 \cdot H^T + n$$  
  (Eq.4.9.1.1.3-1)

  The combiner, then, utilizes
  
  $$w_0 = [1\ 1]$$  
  (Eq.4.9.1.1.3-2)

  for the combination. However, for the specific case of $m = 0$, multiplying vector $w_m$ is not necessary and left here for illustration purposes only. The ‘combiner’ block performs the following combination,

  $$\tilde{S} = y H^* \cdot w_0^T$$  
  (Eq.4.9.1.1.3-3)

  $$\tilde{S} = y [h_1^* h_2^*] \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$  
  (Eq.4.9.1.1.3-4)

  $$\tilde{S} = S(|h_1|^2 + |h_2|^2) + S(h_1^* h_2 + h_1 h_2^*) + n h_1^* + n h_2^*$$  
  (Eq.4.9.1.1.3-5)

  which is, then, passed to the MML detector to perform the symbol estimation.
- If the ‘combiner’ block receives $m = 1$, then,
  
  $$y = G_1 \cdot H^T + n$$  
  (Eq.4.9.1.1.3-6)

  The combiner, then, utilizes

  $$w_1 = [1\ -1]$$  
  (Eq.4.9.1.1.3-7)

  yielding,
This is, then, passed to the MML detector to perform the symbol estimation.

**4.9.2 Closed-Loop Transmit Diversity using four antennas**

The channel $\mathbf{H}$ is calculated by using pilot subcarriers in IAS operation mode shown below.

**4.9.2.1 Interference Assisted Scheme (IAS)**

**4.9.2.1.1 Array Gain Maximization Block**

In the case of 4 TX antennas, there are eight unique $G_m$ together with their respective $I_{Am}$ as well as $w_m$, $m \in \{0,1,2,3,4,5,6,7\}$.

$$L_0 = h_1^* h_2 + h_1^* h_3 + h_1^* h_4 + h_2^* h_3 + h_2^* h_4 + h_3^* h_4 + h_4^*$$

(Eq.4.9.2.1.1-1)

$$L_1 = -h_1^* h_2 + h_1^* h_3 + h_1^* h_4 + h_2^* h_3 + h_2^* h_4 + h_3^* h_4 + h_4^*$$

(Eq.4.9.2.1.1-2)

$$L_2 = -h_1^* h_3 - h_1^* h_4 - h_2^* h_3 - h_2^* h_4 - h_3^* h_4 - h_4^*$$

(Eq.4.9.2.1.1-3)

$$L_3 = -h_1^* h_2 - h_1^* h_3 - h_2^* h_4 - h_4^*$$

(Eq.4.9.2.1.1-4)
In order to select the most aligned interference, the ‘array gain maximization’ block performs

\[
\text{arg max}_{m} (I_{am}), \forall m \in \{0,1,2,3,4,5,6,7\}
\]

(Eq.4.9.2.1.1-9)

The index \(m\) of the selected interference is feed backed through the ‘partial feedback channel’ to the transmitter (in 8 bits) as well as to the ‘combiner block’, collocated in the same device.

4.9.2.1.2 IAS Transmitter

- Transmit \(G_0 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000000’;
- Transmit \(G_1 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000001’;
- Transmit \(G_2 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000010’;
- Transmit \(G_3 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000011’;
- Transmit \(G_4 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000100’;
- Transmit \(G_5 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000101’;
- Transmit \(G_6 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000110’;
- Transmit \(G_7 = [s\ s\ s\ s]\) if the feedback received from RX is ‘00000111’;

4.9.2.1.3 Combiner Block

Let \(H = [h_1\ h_2\ h_3\ h_4]\) and \(\tilde{H} = H\).

- If the ‘combiner’ block receives \(m = 000\) from the ‘array gain maximization’ block, it utilizes
\[ w_0 = [1 \ 1 \ 1 \ 1] \quad \text{(Eq.4.9.2.1.3-1)} \]

to perform the combination

\[ \tilde{S} = yH^* \cdot w_0^\top \quad \text{(Eq.4.9.2.1.3-2)} \]

\[ \tilde{S} = y[h_1^* h_2^* h_3^* h_4^*] \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} \quad \text{(Eq.4.9.2.1.3-3)} \]

\[ \tilde{S} = S(|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2) + S(h_1^* h_2 + h_1^* h_3 + h_1^* h_4 + h_2^* h_3 + h_2^* h_4 + h_3^* h_4 + h_4^* h_4 + h_5^* h_5 + h_5^* h_5 + h_5^* h_6 + h_5^* h_6 + h_5^* h_6 + h_5^* h_6)
+ nh_1^* + nh_2^* + nh_3^* + nh_4^* \quad \text{(Eq.4.9.2.1.3-4)} \]

which is, then, passed to the MML detector to perform the symbol estimation.

* If the ‘combiner’ block receives \( m = 001 \) from the ‘array gain maximization’ block, it utilizes

\[ w_1 = [1 \ -1 \ 1 \ -1] \quad \text{(Eq.4.9.2.1.3-5)} \]

and performs the following combination,

\[ \tilde{S} = yH^* \cdot w_1^\top \quad \text{(Eq.4.9.2.1.3-6)} \]

\[ \tilde{S} = y[h_1^* h_2^* h_3^* h_4^*] \begin{pmatrix} 1 \\ -1 \\ 1 \\ -1 \end{pmatrix} \quad \text{(Eq.4.9.2.1.3-7)} \]

\[ \tilde{S} = S(|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2) + S(-h_1^* h_2 - h_1^* h_3 - h_1^* h_4 - h_2^* h_3 - h_2^* h_4 - h_3^* h_4 - h_4^* h_4 + h_5^* h_5 + h_5^* h_5 + h_5^* h_6 + h_5^* h_6 + h_5^* h_6 + h_5^* h_6)
+ nh_1^* - nh_2^* - nh_3^* - nh_4^* \quad \text{(Eq.4.9.2.1.3-8)} \]

which is, then, passed to the MML detector to perform the symbol estimation.

* If the ‘combiner’ block receives \( m = 010 \) from the ‘array gain maximization’ block, it utilizes

\[ w_2 = [1 \ 1 \ -1 \ -1] \quad \text{(Eq.4.9.2.1.3-9)} \]
and performs the following combination,
\[ \tilde{S} = yH^* \cdot w_j^T \]  
(Eq.4.9.2.1.3-10)

\[ \tilde{S} = y[h_j h_{j+1} h_{j+2}] \begin{pmatrix} 1 \\ 1 \\ -1 \\ -1 \end{pmatrix} \]  
(Eq.4.9.2.1.3-11)

\[ \tilde{S} = S([|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2] + S(-h_j h_{j+1} - h_j h_{j+2} - h_j h_{j+3} - h_j h_{j+4} - h_j h_{j+5} - h_j h_{j+6} - h_j h_{j+7} - h_j h_{j+8} + h_{j+1} h_{j+2} + h_{j+1} h_{j+3} + h_{j+1} h_{j+4} + h_j h_{j+5} + nh_j^* - nh_j^* - nh_j^* + nh_j^*) \]  
(Eq.4.9.2.1.3-12)

which is, then, passed to the MML detector to perform the symbol estimation.

- If the ‘combiner’ block receives \( m = 011 \) from the ‘array gain maximization’ block, it utilizes
\[ w_j = [1 -1 -1 1] \]  
(Eq.4.9.2.1.3-13)

and performs the following combination,
\[ \tilde{S} = yH^* \cdot w_j^T \]  
(Eq.4.9.2.1.3-14)

\[ \tilde{S} = y[h_j h_{j+1} h_{j+2}] \begin{pmatrix} 1 \\ -1 \\ -1 \\ 1 \end{pmatrix} \]  
(Eq.4.9.2.1.3-15)

\[ \tilde{S} = S([|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2] + S(-h_j h_{j+1} - h_j h_{j+2} - h_j h_{j+3} - h_j h_{j+4} - h_j h_{j+5} - h_j h_{j+6} - h_j h_{j+7} - h_j h_{j+8} + h_{j+1} h_{j+2} + h_{j+1} h_{j+3} + h_{j+1} h_{j+4} + h_j h_{j+5} + nh_j^* - nh_j^* - nh_j^* + nh_j^*) \]  
(Eq.4.9.2.1.3-16)

which is, then, passed to the MML detector to perform the symbol estimation.

- If the ‘combiner’ block receives \( m = 100 \) from the ‘array gain maximization’ block, it utilizes
\[ w_j = [1 1 1 -1] \]  
(Eq.4.9.2.1.3-17)

and performs the following combination,
\[ \tilde{S} = yH^* \cdot w_j^T \]  
(Eq.4.9.2.1.3-18)
\[ S = y[h_1^* h_2^* h_3^* h_4^*] \]  
(Eq. 4.9.2.1.3-19)

\[ \tilde{S} = \sum_{i=1}^{4} h_i^* \]  
(Eq. 4.9.2.1.3-20)

which is, then, passed to the MML detector to perform the symbol estimation.

- If the ‘combiner’ block receives \( m = 101 \) from the ‘array gain maximization’ block, it utilizes

\[ w_5 = [1 \ 1 \ -1 \ 1] \]  
(Eq. 4.9.2.1.3-21)

and performs the following combination,

\[ \tilde{S} = yH^* \cdot \tilde{w}_5^T \]  
(Eq. 4.9.2.1.3-22)

\[ \tilde{S} = y[h_1^* h_2^* h_3^* h_4^*] \]  
(Eq. 4.9.2.1.3-23)

\[ \tilde{S} = \sum_{i=1}^{4} h_i^* \]  
(Eq. 4.9.2.1.3-24)

which is, then, passed to the MML detector to perform the symbol estimation.

- If the ‘combiner’ block receives \( m = 110 \) from the ‘array gain maximization’ block, it utilizes

\[ w_6 = [1 \ -1 \ 1 \ 1] \]  
(Eq. 4.9.2.1.3-25)

and performs the following combination,

\[ \tilde{S} = yH^* \cdot \tilde{w}_6^T \]  
(Eq. 4.9.2.1.3-26)
\[ S = \begin{pmatrix} 1 \\ -1 \\ 1 \\ 1 \end{pmatrix} \]  
(Eq.4.9.2.1.3-27)

\[ S = S(|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2) + S(-h_1^*h_2 - h_2^*h_3 - h_2h_4 - h_3^*h_4 + h_1^*h_3 + h_1h_4^* \\
+ h_1^*h_4 + h_2^*h_3 + h_2h_4^* + h_3^*h_4^*) + nh_1^* - nh_2^* + nh_3^* + nh_4^* \]  
(Eq.4.9.2.1.3-28)

which is, then, passed to the MML detector to perform the symbol estimation.

- If the ‘combiner’ block receives \( m = 111 \) from the ‘array gain maximization’ block, it utilizes

\[ w_j = [-1, 1, 1, 1] \]  
(Eq.4.9.2.1.3-29)

and performs the following combination,

\[ S = yH^*w_j^T \]  
(Eq.4.9.2.1.3-30)

\[ S = \begin{pmatrix} 1 \\ -1 \\ 1 \\ 1 \end{pmatrix} \]  
(Eq.4.9.2.1.3-31)

\[ S = S(|h_1|^2 + |h_2|^2 + |h_3|^2 + |h_4|^2) + S(-h_1^*h_2 - h_2^*h_3 - h_2h_4 - h_3^*h_4 + h_1^*h_3 + h_1h_4^* \\
+ h_1^*h_4 + h_2^*h_3 + h_2h_4^* + h_3^*h_4^*) - nh_1^* + nh_2^* + nh_3^* + nh_4^* \]  
(Eq.4.9.2.1.3-32)

which is, then, passed to the MML detector to perform the symbol estimation.

### 4.9.3 IAS with Maximum Ratio Combining (MRC)

When two antennas are available in the receive terminal, maximum ratio combining (MRC) can be utilized, therefore significantly enhancing link reliability.

In order to use MRC, little modification is necessary. The ‘Array Gain Maximization’ block, now, performs

\[ \arg\max (I_{m\alpha} + I_\alpha), \forall m \in \{0,1\} \]  
(Eq.4.9.3-1)

for 2 TX antennas, and
\[ \arg \max_m (I_{Am} + I'_{Am}), \forall m \in \{0,1,2,3,4,5,6,7\} \]  
(Eq.4.9.3-2)

for 4 TX antennas. Here, \( I_{Am} \) is the array interference in the first RX antenna, given in the previous sections and \( I'_{Am} \) represents the array interferences in the second RX antenna. Since the channel to the second RX antenna is given by \( H = [h_3 \ h_4] \), for two TX antennas, and \( H = [h_5 \ h_6 \ h_7 \ h_8] \), for 4 TX antennas, \( I_{Am} \) becomes

\[ I_{A0} = h^*_5 h_4 + h^*_3 h_4 \]  
(Eq.4.9.3-3)

\[ I_{A1} = -h^*_5 h_6 + h^*_3 h_6 \]  
(Eq.4.9.3-4)

or

\[ I_{A0} = h^*_5 h_6 - h^*_3 h_6 + h^*_5 h_7 - h^*_3 h_7 - h^*_5 h_8 - h^*_3 h_8 \]  
(Eq.4.9.3-5)

\[ I_{A1} = -h^*_5 h_9 - h^*_3 h_9 - h^*_5 h_10 - h^*_3 h_10 - h^*_5 h_11 - h^*_3 h_11 - h^*_5 h_15 - h^*_3 h_15 \]  
(Eq.4.9.3-6)

**Note:** The equations for \( I_{A2}, I_{A3}, I_{A4}, \ldots, I_{A7} \) follow in a similar pattern, each representing the interference terms for different choices of \( m \) values.

\[ I_{A2} = h^*_5 h_7 + h^*_3 h_7 - h^*_5 h_8 + h^*_3 h_8 \]  
(Eq.4.9.3-7)

\[ I_{A3} = h^*_5 h_9 - h^*_3 h_9 - h^*_5 h_10 + h^*_3 h_10 \]  
(Eq.4.9.3-8)

\[ I_{A4} = h^*_5 h_11 - h^*_3 h_11 \]  
(Eq.4.9.3-9)

\[ I_{A5} = h^*_5 h_{15} - h^*_3 h_{15} \]  
(Eq.4.9.3-10)

\[ I_{A6} = h^*_5 h_3 - h^*_3 h_3 \]  
(Eq.4.9.3-11)

\[ I_{A7} = h^*_5 h_5 - h^*_3 h_5 \]  
(Eq.4.9.3-12)
The \( m \) that maximizes the summation \((I_{Am} + I'_{Am})\) is feedbacked to the transmitter (in 8 bits) and to the ‘combiner’ block, which, will combine the received signal, just as described in the previous sections, in order to deliver \( \tilde{S} + \tilde{S}' \) to the ML detector. Note that \( \tilde{S} \) is given in the previous sections and \( \tilde{S}' \) is given by

\[
\tilde{S}' = y' H^\top w_m^j
\]

(Eq. 4.9.3-13)

with \( y' \) being the signal received by the second RX antenna and \( H = [h_3 h_4] \), for 2TX, or \( H = [h_5 h_6 h_7 h_8] \), for 4 TX.

### 4.9.4 Relevant changes

When using the scheme specified in Section 4.9, the following changes shall be made.

Table 11.11 REP-REQ management message encodings of [5] is replaced with the following Table.

<table>
<thead>
<tr>
<th>Name</th>

Chapter 5 Communication control method for MAC

5.1 Introduction

In this chapter, the Medium Access Control (MAC) Layer specification of the 200 MHz-band Wireless Broadband Communication System is described. Service-specific Convergence Sublayer (CS) and MAC common part sublayer are described in 5.2 and 5.3 respectively.

This chapter specifies the required parameters selected from the basement document of IEEE802.16•2009. Those sets include both the Mobile WiMAX [6] as is basis and a subset of IEEE802.16•2009 for Mode1, and Mode2. The parameters labeled with (optional) shows that is contained in WiMAX as mandatory. Appendix X lists those differences in the parameter sets among these three base systems.

5.2 Service-specific CS
5.2.1 Packet CS
5.2.1.1 MAC SDU format
    Refer to “5.2.1 MAC SDU format” of [5].

5.2.1.2 Classification
    Refer to “5.2.2 Classification” of [5].

5.2.1.3 Payload header suppression (PHS)
    Refer to “5.2.3 Payload header suppression (PHS)” of [5].

5.2.1.3.1 PHS operation
    Refer to “5.2.3.1 PHS operation” of [5].

5.2.1.3.2 PHS signaling
    Refer to “5.2.3.2 PHS signaling” of [5].

5.2.1.4 IP specific part
    Refer to “5.2.5 IP specific part” of [5].

5.2.1.4.1 IP CS PDU format
    Refer to “5.2.5.1 IP CS PDU format” of [5].
5.3 MAC common part sublayer

5.3.1 Data/Control plane

5.3.1.1 Addressing and connections

5.3.1.1.1 Point-to-multipoint (PMP) operation overview

Refer to “6.1 Point-to-multipoint (PMP) operation overview” of [5].

5.3.1.2 MAC PDU formats

Refer to “6.3.2 MAC PDU formats” of [5].

5.3.1.2.1 MAC header formats

Refer to “6.3.2.1 MAC header formats” of [5].

5.3.1.2.1.1 Generic MAC header

Refer to “6.3.2.1.1 Generic MAC header” of [5].

5.3.1.2.1.2 MAC header without payload

Refer to “6.3.2.1.2 MAC header without payload” of [5].

5.3.1.2.1.2.1 Bandwidth request (BR) header

Refer to “6.3.2.1.2.1.1 Bandwidth request (BR) header” of [5].

5.3.1.2.2 MAC subheaders and special payloads

Refer to “6.3.2.2 MAC subheaders and special payloads” of [5].

5.3.1.2.2.1 Fragmentation subheader (FSH)

Refer to “6.3.2.2.1 Fragmentation subheader (FSH)” of [5].

5.3.1.2.3 MAC management messages

Refer to “6.3.2.3 MAC management messages” of [5].

5.3.1.2.3.1 DCD (DL channel descriptor) message

Refer to “6.3.2.3.1 DCD (DL channel descriptor) message” of [5].
5.3.1.2.3.2 DL-MAP (Downlink map) message
   Refer to “6.3.2.3.2 DL-MAP (Downlink map) message” of [5].

5.3.1.2.3.3 UCD (UL channel descriptor) message
   Refer to “6.3.2.3.3 UCD (UL channel descriptor) message” of [5].

5.3.1.2.3.4 UL-MAP (UL map) message
   Refer to “6.3.2.3.4 UL-MAP (UL map) message” of [5].

5.3.1.2.3.5 RNG-REQ (ranging request) message
   Refer to “6.3.2.3.5 RNG-REQ (ranging request) message” of [5].

5.3.1.2.3.6 RNG-RSP (ranging response) message
   Refer to “6.3.2.3.6 RNG-RSP (ranging response) message” of [5].

5.3.1.2.3.7 REG-REQ (registration request) message
   Refer to “6.3.2.3.7 REG-REQ (registration request) message” of [5].

5.3.1.2.3.8 REG-RSP (registration response) message
   Refer to “6.3.2.3.8 REG-RSP (registration response) message” of [5].

5.3.1.2.3.9 DSA-REQ message
   Refer to “6.3.2.3.10 DSA-REQ message” of [5].

5.3.1.2.3.9.1 BS-Initiated DSA
   Refer to “6.3.2.3.10.2 BS-Initiated DSA” of [5].

5.3.1.2.3.10 DSA-RSP message
   Refer to “6.3.2.3.11 DSA-RSP message” of [5].

5.3.1.2.3.10.1 BS-Initiated DSA
   Refer to “6.3.2.3.11.2 BS-Initiated DSA” of [5].

5.3.1.2.3.11 DSA-ACK message
   Refer to “6.3.2.3.12 DSA-ACK message” of [5].
5.3.1.2.3.12 SBC-REQ (SS basic capability request) message
   Refer to “6.3.2.3.23 SBC-REQ (SS basic capability request) message” of [5].

5.3.1.2.3.13 SBC-RSP (SS basic capability response) message
   Refer to “6.3.2.3.24 SBC-RSP (SS basic capability response) message” of [5].

5.3.1.2.3.14 DREG-CMD (de/reregister command) message
   Refer to “6.3.2.3.26 DREG-CMD (de/reregister command) message” of [5].

5.3.1.2.3.15 ARQ-Feedback message
   Refer to “6.3.2.3.30 ARQ-Feedback message” of [5].

5.3.1.2.3.16 ARQ-Discard message
   Refer to “6.3.2.3.31 ARQ-Discard message” of [5].

5.3.1.2.3.17 ARQ-Reset message
   Refer to “6.3.2.3.32 ARQ-Reset message” of [5].

5.3.1.2.3.18 Channel Measurement REP-REQ/RSP (report request/response)
   Refer to “6.3.2.3.33 Channel Measurement REP-REQ/RSP (report request/response)” of [5].

5.3.1.2.3.19 DREG-REQ (SS deregistration request) message
   Refer to “6.3.2.3.37 DREG-REQ(SS deregistration request) message” of [5].

5.3.1.2.3.20 HARQ MAP message(Optional)
   Refer to “6.3.2.3.38 HARQ MAP message” of [5].

5.3.1.3 Construction and transmission of MAC PDUs
   Refer to “6.3.3 Construction and transmission of MAC PDUs” of [5].

5.3.1.3.1 Conventions
   Refer to “6.3.3.1 Conventions” of [5].
5.3.1.3.2 Concatenation
Refer to “6.3.3.2 Concatenation” of [5].

5.3.1.3.3 Fragmentation
Refer to “6.3.3.3 Fragmentation” of [5].

5.3.1.3.3.1 Non-ARQ connections
Refer to “6.3.3.3.1 Non-ARQ connections” of [5].

5.3.1.3.3.2 ARQ-enabled connections
Refer to “6.3.3.3.2 ARQ-enabled connections” of [5].

5.3.1.3.4 CRC calculation
Refer to “6.3.3.5 CRC calculation” of [5].

5.3.1.3.5 CRC32 calculation for OFDMA mode
Refer to “6.3.3.5.2 CRC32 calculation for OFDMA mode” of [5].

5.3.1.3.6 Padding
Refer to “6.3.3.7 Padding” of [5].

5.3.1.4 ARQ mechanism
Refer to “6.3.4 ARQ mechanism” of [5].

5.3.1.4.1 ARQ block usage
Refer to “6.3.4.1 ARQ block usage” of [5].

5.3.1.4.2 ARQ Feedback IE format
Refer to “6.3.4.2 ARQ Feedback IE format” of [5].

5.3.1.4.3 ARQ parameters
Refer to “6.3.4.3 ARQ parameters” of [5].

5.3.1.4.3.1 ARQ_BSN_MODULUS
Refer to “6.3.4.3.1 ARQ_BSN_MODULUS” of [5].
5.3.1.4.3.2 ARQ_WINDOW_SIZE
   Refer to “6.3.4.3.2 ARQ_WINDOW_SIZE” of [5].

5.3.1.4.3.3 ARQ_BLOCK_LIFETIME
   Refer to “6.3.4.3.3 ARQ_BLOCK_LIFETIME” of [5].

5.3.1.4.3.4 ARQ_RETRY_TIMEOUT
   Refer to “6.3.4.3.4 ARQ_RETRY_TIMEOUT” of [5].

5.3.1.4.3.5 ARQ_SYNC_LOSS_TIMEOUT
   Refer to “6.3.4.3.5 ARQ_SYNC_LOSS_TIMEOUT” of [5].

5.3.1.4.3.6 ARQ_RX_PURGE_TIMEOUT
   Refer to “6.3.4.3.6 ARQ_RX_PURGE_TIMEOUT” of [5].

5.3.1.4.3.7 ARQ_BLOCK_SIZE
   Refer to “6.3.4.3.7 ARQ_BLOCK_SIZE” of [5].

5.3.1.4.4 ARQ procedures
5.3.1.4.4.1 ARQ state machine variables
   Refer to “6.3.4.4.1 ARQ state machine variables” of [5].

5.3.1.4.5 ARQ operation
   Refer to “6.3.4.6 ARQ operation” of [5].

5.3.1.4.6.1 Sequence number comparison
   Refer to “6.3.4.6.1 Sequence number comparison” of [5].

5.3.1.4.6.2 Transmitter state machine
   Refer to “6.3.4.6.2 Transmitter state machine” of [5].

5.3.1.4.6.3 Receiver state machine
   Refer to “6.3.4.6.3 Receiver state machine” of [5].
5.3.1.5 Scheduling services
  Refer to “6.3.5 Scheduling services” of [5].

5.3.1.5.1 Outbound transmission scheduling
  Refer to “6.3.5.1 Outbound transmission scheduling” of [5].

5.3.1.5.2 UL request/grant scheduling
  Refer to “6.3.5.2 UL request/grant scheduling” of [5].

5.3.1.5.2.1 Unsolicited grant service (UGS)
  Refer to “6.3.5.2.1 Unsolicited grant service (UGS)” of [5].

5.3.1.5.2.2 Best effort (BE) service
  Refer to “6.3.5.2.4 Best effort (BE) service” of [5].

5.3.1.6 Bandwidth allocation and request mechanisms
  Refer to “6.3.6 Bandwidth allocation and request mechanisms” of [5].

5.3.1.6.1 Requests
  Refer to “6.3.6.1 Requests” of [5].

5.3.1.6.2 Grants
  Refer to “6.3.6.2 Grants” of [5].

5.3.1.6.3 Contention-based CDMA BRs
  Refer to “6.3.6.5 Contention-based CDMA BRs for WirelessMAN-OFDMA” of [5].

5.3.1.7 MAC support of PHY
  Refer to “6.3.7 MAC support of PHY” of [5].

5.3.1.7.1 Time division duplex (TDD)
  Refer to “6.3.7.2 Time division duplex (TDD)” of [5].

5.3.1.7.2 DL-MAP message
  Refer to “6.3.7.3 DL-MAP message” of [5].
5.3.1.7.3 UL-MAP message
   Refer to “6.3.7.4 UL-MAP message” of [5].

5.3.1.7.3.1 UL timing
   Refer to “6.3.7.4.1 UL timing” of [5].

5.3.1.7.3.2 UL allocations
   Refer to “6.3.7.4.2 UL allocations” of [5].

5.3.1.7.3.3 UL interval definition
   Refer to “6.3.7.4.3 UL interval definition” of [5].

5.3.1.7.4 Map relevance and synchronization.
   Refer to “6.3.7.5 Map relevance and synchronization” of [5].

5.3.1.7.4.1 OFDMA PHY
   Refer to “6.3.7.5.3 WirelessMAN-OFDMA PHY” of [5].

5.3.1.8 Network entry and initialization
   Refer to “6.3.9 Network entry and initialization” of [5].

5.3.1.8.1 Scanning and synchronization to the DL
   Refer to “6.3.9.1 Scanning and synchronization to the DL” of [5].

5.3.1.8.2 Obtain DL parameters
   Refer to “6.3.9.2 Obtain DL parameters” of [5].

5.3.1.8.3 Obtain UL parameters
   Refer to “6.3.9.3 Obtain UL parameters” of [5].

5.3.1.8.4 Message flows during scanning and UL parameter acquisition
   Refer to “6.3.9.4 Message flows during scanning and UL parameter acquisition” of [5].
5.3.1.8.5 Initial ranging and automatic adjustments
   Refer to “6.3.9.5 Initial ranging and automatic adjustments” of [5].

5.3.1.8.5.1 Contention-based initial ranging and automatic adjustments
   Refer to “6.3.9.5.1 Contention-based initial ranging and automatic adjustments” of [5].

5.3.1.8.6 Ranging parameter adjustment
   Refer to “6.3.9.6 Ranging parameter adjustment” of [5].

5.3.1.8.7 Negotiate basic capabilities
   Refer to “6.3.9.7 Negotiate basic capabilities” of [5].

5.3.1.8.8 Registration
   Refer to “6.3.9.9 Registration” of [5].

5.3.1.8.9 Establishing provisioned connections
   Refer to “6.3.9.13 Establishing provisioned connections” of [5].

5.3.1.8.10 Forcing MSs to perform network entry at once
   Refer to “6.3.9.14 Forcing MSs to perform network entry at once” of [5].

5.3.1.9 Ranging
   Refer to “6.3.10 Ranging” of [5].

5.3.1.9.1 UL periodic ranging
   Refer to “6.3.10.2 UL periodic ranging” of [5].

5.3.1.9.2 OFDMA-based ranging
   Refer to “6.3.10.3 OFDMA-based ranging” of [5].

5.3.1.9.2.1 Contention-based initial ranging and automatic adjustments
   Refer to “6.3.10.3.1 Contention-based initial ranging and automatic adjustments” of [5].

5.3.1.9.2.2 Periodic ranging and automatic adjustments
   Refer to “6.3.10.3.2 Periodic ranging and automatic adjustments” of [5].
5.3.1.10 Quality of service (QoS)
   Refer to “6.3.14 Quality of service (QoS)” of [5].

5.3.1.10.1 Theory of operation
   Refer to “6.3.14.1 Theory of operation” of [5].

5.3.1.10.2 Service flows
   Refer to “6.3.14.2 Service flows” of [5].

5.3.1.10.3 Object model
   Refer to “6.3.14.3 Object model” of [5].

Chapter 6 Measurement Method

In this chapter, the measurement methods to verify the technical requirements of the 200 MHz-band Wireless Broadband Communication System is described. The measurement methods for the Transmitter and Receiver should be in accordance with those described in Sections 6.1 and 6.2 respectively or other those method equivalent or more with these method. For those measurement items not covered in these should be, however, in accordance with generally practiced method.

6.1 Transmitter

6.1.1 Frequency tolerance

While transmitting the unmodulated wave (carrier), make the measurement with a frequency meter (in the case of burst wave, measure the average value within the burst). When the equipment has more than one antenna terminal, frequency should be measured at every terminal and the maximum deviations from the nominal should be considered the frequency deviation. However, when it has been verified that the frequencies at these terminals are phase-synchronized with a single reference frequency, the measurement can be performed at one antenna terminal.

Note that when the measurement is made with such a dedicated instrument as a waveform analyzer, the measurement can be performed while transmitting the modulated waves.

6.1.2 Occupied bandwidth

Measure with such an instrument as a spectrum analyzer the total power of the distributed spectral with the standard encoding test signal (such as the binary pseudo-noise sequence signal whose code length is 511 bits, the same applies hereinafter) is applied, and measure the frequency bandwidth where the sum of power in each of the highest and lowest areas of the spectral distribution is 0.5% of the total power. When the equipment has more than one antenna terminal, the occupied bandwidth should be measured at every terminal and the maximum one of these bandwidths should be considered the occupied bandwidth.

However, when different frequencies are emitted from different antenna terminals, perform the measurement by connecting all the antenna terminals with such a device as a calibrated RF coupler to combine the signals from all of the antenna terminals.

6.1.3 Output power

Measure with an RF power meter the average power when the standard encoding test signal
is applied to the input signal terminal. When the equipment has more than one antenna terminal, the output power should be measured at every terminals and the sum of these powers should be considered the output power.

It is desirable to perform the measurement with the continuous transmission waves, but when measurement has to be performed using the burst transmission waves, the average power should be measured over a period of time sufficiently longer than the burst repetition period which leads to the maximum transmission time ratio, and the average power should be obtained by multiplying this measured average power with the inverse of the transmission time ratio. However, in the case of an adaptive array antenna (whose radiation directivity is controlled by varying power and phase of each antenna element and which has the capability to keep its total power constant, when the power of one of antenna elements is increased, by decreasing the power of other antenna elements; the same applies hereinafter), the measurement should be performed in the condition where the sum of output power reaches the maximum value.

6.1.4 Adjacent channel leakage power

Using the standard encoding test signal as the input signal, measure the power which falls within the specified adjacent channel band with such an instrument as a spectrum analyzer when using the burst wave, and the measurement should be performed with the peak detector and maximum hold modes while sweeping at a rate such that one or more bursts can be included in one sampling point. When the equipment has more than one antenna terminal, the measurement should be performed at every terminal and the sum of these measurements should be considered the adjacent channel leakage power. When using a continuous wave, measure the power which falls within the specified adjacent channel band with a power measurement receiver or spectrum analyzer and the sum of measurements should be considered the adjacent channel leakage power. However, in the case of the adaptive array antenna, the measurement should be performed in the condition where the sum of output power is at maximum value while the power of one antenna element is kept at its maximum.

6.1.5 Spurious emission

To the extent possible, it is desirable to measure the spurious emission in the spurious area from 9 kHz to 110 GHz; however, for the time being it is acceptable to measure emission level from 9 kHz to the frequency of the 10th harmonic. The average power (or the average power within the burst in the case when using the burst wave) of the spurious emission should be measured with a spectrum analyzer when the standard encoding test signal is applied as the
input signal. When the equipment has more than one antenna terminal, the output power should be measured at every terminal and the sum of these powers should be considered the spurious emission. In this measurement, the resolution bandwidth of the spectrum analyzer should be set to the reference bandwidth. However, in the case of the adaptive array antenna, the measurement should be performed in the condition where the sum of output power is at maximum value while the power of one antenna element is kept at its maximum. Follow the above requirements in performing measurement in the out-of-band area.

6.2 Receiver

6.2.1 Receiving sensitivity

Receiving sensitivity is the minimum receiving power of the signal from the standard signal generator modulated with the specified modulation method and measured at the antenna terminal when the quality of the signal becomes the specified quality (BER: Bit Error Rate), and it shall be equal to or less than the allowable value (the reference sensitivity) under the static condition. So long as the packet error rate (PER) can be uniquely converted to the BER, the PER can be measured and converted to the BER, provided that the conversion equation is clearly shown. (The same applies hereinafter).

6.2.2 Spurious response

Apply a signal modulated with the specified modulation method from a standard signal generator and set the level of the standard signal generator to the specified desired signal level. Also set the level of one non-modulated interference signal to the specified level, then sweep its frequency to confirm that the signal can be received with a quality equal to or better than the specified level (i.e., at a bit error rate equal to or less than the specified level).

6.2.3 Adjacent channel selectivity

Apply a signal modulated with the specified modulation method from a standard signal generator and set the level of the standard signal generator to the specified desired signal level. Set the level of the adjacent interference signal from another standard signal generator, which is a modulated wave centered at the adjacent carrier frequency, to the specified adjacent channel level to confirm that the wanted signal can be received with a quality equal to or better than the specified level (i.e., at a bit error rate equal to or less than the specified level).

6.2.4 Inter-modulation characteristics

Apply a signal modulated with the specified modulation method from a standard signal
generator and set the level of the standard signal generator to the specified desired signal level. Set the levels of two interference signals with equal power from another standard signal generators, specifically, a non-modulated wave at the adjacent channel frequency and a modulated wave at the next adjacent channel frequency, to confirm that the signal can be received with a quality equal to or better than the specified level (i.e., at a bit error rate equal to or less than the specified level).

6.2.5 Conducted spurious

Make the measurement with a spectrum analyzer. The resolution bandwidth of the spectrum analyzer should be set to the measurement bandwidth. When the equipment has more than one antenna terminal, the measurement should be performed at every terminal and the sum of these measurements should be considered the conducted spurious level incidentally leaked.

6.3 Data transmission speed

Data transmission speed would be preferably measured with dedicated data transmission speed measuring equipment for both UL and DL directions. If such device is not available, appropriate measuring equipment generally practiced for data transmission speed measurement would be applied.

Attachment 1 Summary of this ARIB Standard

The following two Tables summarize the description of “Chapter 4 PHY” and “Chpater 5 MAC” of this ARIB standard, respectively, on a section-by-section basis. In many sections, Mode 1 with FFT-512 (Mobile WiMAX), Mode 1 with FFT-1024 and Mode 2 (FFT-1024) have common specifications referring to the relevant sections of IEEE802.16-2009. There are some differences of the specifications among Mode 1 FFT-512, Mode 1 FFT-1024 and Mode 2.

Attachment 2 Interoperability Test

In the wireless systems specified by this standard, the interoperability shall be achieved between the systems with exactly the same specification including frame length, DL/UL ratio, namely between the systems within the same column including the DL/UL ratio in Table 1-1. When interoperability tests are required, appropriate tests should be chosen in the test procedures specified in [7] by those who are concerned.
Attachment 3 Coexistence between Systems

In order to show the coexistence conditions between the systems using portable BS and MS, the required distances between the systems are investigated by using a simple usage model and some assumptions. Two cases, Case 1 and Case 2, described below are investigated in this study.

Case 1
Systems between the 200-MHz-band broadband wireless communication systems with exactly the same specifications such as frame length, DL/UL ratio etc.

Case 2
Systems between the 200-MHz band broadband wireless communication systems with different specifications, for example, between the system with 5 msec frame length and the system with 10 msec frame length

A3-1 Model
Base system is shown in the Figure below.

Figure A3·1: Base model for coexistence investigation

A3-2 Parameters
The upper limit of adjacent channel leakage power show below is used for the worst case investigation.

-21dBc (in 4.8 MHz band where 2.6-7.4 MHz offset from the center of the relevant channel)
-41dBc (in 4.8 MHz band where 7.6-12.4 MHz offset from the center of the relevant channel)
Figure A3-2 shows the example of adjacent channel leakage power level. In this case, the channel with the center frequency of 185 MHz is used for the communication. In this channel, output power is 37dBm (5W). The leakage power in the adjacent channel between 177.6 MHz and 182.4 MHz is 16 dBm, 21 dB lower than the output power of 37 dBm.

Permissible interference level is assumed to be 3 dB lower than the environmental noise determined by the Recommendation ITU-R P.372.

A3-3 Interference Scenarios

In Case 1, two interference scenarios shown below are considered. In this case, interference is from portable BS to MS or from MS to portable BS. The first scenario (Fig.A3-3(a)) is the interference from portable BS to MS and the second scenario (Fig.A3-3(b)) is the interference from MS to portable BS. In both scenarios, three patterns of the channels used by interfering system and interfered system shown by Figure A3-4.
In Case 2, on the other hand, interferences occur from both portable BS and MS of the other system. The first scenario (Fig.A3-5(a)) is the interference from portable BS and MS to portable BS of the interfered system and the second scenario (Fig.A4-5(b)) is the interference from portable BS and MS to MS of the interfered system. In both scenarios, three patterns of the channels used by interfering system and interfered system shown by Figure A3-4.
(a) First interference scenario (portable BS and MS to Portable BS) in Case 2

(b) Second interference scenario (Portable BS and MS to MS) in Case 2

Grateful acknowledgment is made to Cable Television Laboratories for the permission to use the following source material:

Radio Frequency Interface Specification (version 1.1), part of Data-Over-Cable Service Interface Specifications, © Copyright 1999, Cable Television Laboratories.

Baseline Privacy Plus Interface Specification, © Copyright 1999, Cable Television Laboratories.

Abstract: This standard specifies the air interface, including the medium access control layer (MAC) and physical layer (PHY), of combined fixed and mobile point-to-multipoint broadband wireless access (BWA) systems providing multiple services. The MAC is structured to support multiple physical layer (PHY) specifications, each suited to a particular operational environment. The standard enables rapid worldwide deployment of innovative, cost effective, and interoperable multivendor broadband wireless access products, facilitates competition in broadband access by providing alternatives to wireline broadband access, encourages consistent worldwide spectrum allocations, and accelerates the commercialization of broadband wireless access systems. The standard is a revision of IEEE Std 802.16-2004, and consolidates material from IEEE Std 802.16e™-2005, IEEE 802.16-2004/Cor1-2005, IEEE 802.16f™-2005, and IEEE Std 802.16g™-2007, along with additional maintenance items and enhancements to the management information base specifications. This revision supersedes and makes obsolete IEEE Std 802.16-2004 and all of its subsequent amendments and corrigenda.

IEEE Standards documents are developed within the IEEE Societies and the Standards Coordinating Committees of the IEEE Standards Association (IEEE-SA) Standards Board. The IEEE develops its standards through a consensus development process, approved by the American National Standards Institute, which brings together volunteers representing varied viewpoints and interests to achieve the final product. Volunteers are not necessarily members of the Institute and serve without compensation. While the IEEE administers the process and establishes rules to promote fairness in the consensus development process, the IEEE does not independently evaluate, test, or verify the accuracy of any of the information or the soundness of any judgments contained in its standards.

Use of an IEEE Standard is wholly voluntary. The IEEE disclaims liability for any personal injury, property or other damage, of any nature whatsoever, whether special, indirect, consequential, or compensatory, directly or indirectly resulting from the publication, use of, or reliance upon this, or any other IEEE Standard document.

The IEEE does not warrant or represent the accuracy or content of the material contained herein, and expressly disclaims any express or implied warranty, including any implied warranty of merchantability or fitness for a specific purpose, or that the use of the material contained herein is free from patent infringement. IEEE Standards documents are supplied “AS IS.”

The existence of an IEEE Standard does not imply that there are no other ways to produce, test, measure, purchase, market, or provide other goods and services related to the scope of the IEEE Standard. Furthermore, the viewpoint expressed at the time a standard is approved and issued is subject to change brought about through developments in the state of the art and comments received from users of the standard. Every IEEE Standard is subjected to review at least every five years for revision or reaffirmation. When a document is more than five years old and has not been reaffirmed, it is reasonable to conclude that its contents, although still of some value, do not wholly reflect the present state of the art. Users are cautioned to check to determine that they have the latest edition of any IEEE Standard.

In publishing and making this document available, the IEEE is not suggesting or rendering professional or other services for, or on behalf of, any person or entity. Nor is the IEEE undertaking to perform any duty owed by any other person or entity to another. Any person utilizing this, and any other IEEE Standards document, should rely upon his or her independent judgment in the exercise of reasonable care in any given circumstances or, as appropriate, seek the advice of a competent professional in determining the appropriateness of a given IEEE standard.

Interpretations: Occasionally questions may arise regarding the meaning of portions of standards as they relate to specific applications. When the need for interpretations is brought to the attention of IEEE, the Institute will initiate action to prepare appropriate responses. Since IEEE Standards represent a consensus of concerned interests, it is important to ensure that any interpretation has also received the concurrence of a balance of interests. For this reason, IEEE and the members of its societies and Standards Coordinating Committees are not able to provide an instant response to interpretation requests except in those cases where the matter has previously received formal consideration. A statement, written or oral, that is not processed in accordance with the IEEE-SA Standards Board Operations Manual shall not be considered the official position of IEEE or any of its committees and shall not be considered to be, nor be relied upon as, a formal interpretation of the IEEE. At lectures, symposia, seminars, or educational courses, an individual presenting information on IEEE standards shall make it clear that his or her views should be considered the personal views of that individual rather than the formal position, explanation, or interpretation of the IEEE.

Comments for revision of IEEE Standards are welcome from any interested party, regardless of membership affiliation with IEEE. Suggestions for changes in documents should be in the form of a proposed change of text, together with appropriate supporting comments. Comments on standards and requests for interpretations should be submitted to the following address:

Secretary, IEEE-SA Standards Board
445 Hoes Lane
Piscataway, NJ 08854

Authorization to photocopy portions of any individual standard for internal or personal use is granted by The Institute of Electrical and Electronics Engineers, Inc., provided that the appropriate fee is paid to Copyright Clearance Center. To arrange for payment of licensing fee, please contact Copyright Clearance Center, Customer Service, 222 Rosewood Drive, Danvers, MA 01923 USA; +1 978 750 8400. Permission to photocopy portions of any individual standard for educational classroom use can also be obtained through the Copyright Clearance Center.
Introduction

This standard specifies the air interface of combined fixed broadband wireless access (BWA) systems supporting multimedia services. The medium access control layer (MAC) supports a primarily point-to-multipoint architecture. The MAC is structured to support multiple physical layer (PHY) specifications, each suited to a particular operational environment. For operational frequencies from 10–66 GHz, the WirelessMAN-SC PHY, based on single-carrier modulation, is specified. For frequencies below 11 GHz, where propagation without a direct line of sight must be accommodated, two alternatives are provided: WirelessMAN-OFDM (using orthogonal frequency-division multiplexing) and WirelessMAN-OFDMA (using orthogonal frequency-division multiple access). This standard is a revision of IEEE Std 802.16-2004 and consolidates material from IEEE 802.16e-2005, IEEE 802.16-2004/Cor1-2005, IEEE 802.16f-2005, and IEEE 802.16g-2007, along with additional maintenance items and enhancements to the management information base specifications. This revision supersedes and makes obsolete IEEE Std 802.16-2004 as well as IEEE 802.16e-2005, IEEE 802.16-2004/Cor1-2005, IEEE 802.16f-2005, and IEEE 802.16g-2007.

Conformance test methodology

The multipart conformance test documents for IEEE Std 802.16 are designated by “IEEE Standard 802.16/ConformanceXX.”

Notice to users

Laws and regulations

Users of these documents should consult all applicable laws and regulations. Compliance with the provisions of this standard does not imply compliance to any applicable regulatory requirements. Implementers of the standard are responsible for observing or referring to the applicable regulatory requirements. IEEE does not, by the publication of its standards, intend to urge action that is not in compliance with applicable laws, and these documents may not be construed as doing so.

Copyrights

This document is copyrighted by the IEEE. It is made available for a wide variety of both public and private uses. These include both use, by reference, in laws and regulations, and use in private self-regulation, standardization, and the promotion of engineering practices and methods. By making this document available for use and adoption by public authorities and private users, the IEEE does not waive any rights in copyright to this document.

Updating of IEEE documents

Users of IEEE standards should be aware that these documents may be superseded at any time by the issuance of new editions or may be amended from time to time through the issuance of amendments, corrigenda, or errata. An official IEEE document at any point in time consists of the current edition of the document together with any amendments, corrigenda, or errata then in effect. In order to determine whether a given document is the current edition and whether it has been amended through the issuance of amendments, corrigenda, or errata, visit the IEEE Standards Association website at http://ieeexplore.ieee.org/xpl/standards.jsp, or contact the IEEE at the address listed previously.
For more information about the IEEE Standards Association or the IEEE standards development process, visit the IEEE-SA website at http://standards.ieee.org.

**Errata**

Errata, if any, for this and all other standards can be accessed at the following URL: http://standards.ieee.org/reading/ieee/updates/errata/index.html. Users are encouraged to check this URL for errata periodically.

**Interpretations**

Current interpretations can be accessed at the following URL: http://standards.ieee.org/reading/ieee/interp/index.html.

**Patents**

Attention is called to the possibility that implementation of this standard may require use of subject matter covered by patent rights. By publication of this standard no position is taken with respect to the existence or validity of any patent rights in connection therewith. The IEEE is not responsible for identifying Essential Patent Claims for which a license may be required, for conducting inquiries into the legal validity or scope of Patents Claims or determining whether any licensing terms or conditions provided in connection with submission of a Letter of Assurance, if any, or in any licensing agreements are reasonable or non-discriminatory. Users of this (guide, trial-use, standard, or recommended practice) are expressly advised that determination of the validity of any patent rights, and the risk of infringement of such rights, is entirely their own responsibility. Further information may be obtained from the IEEE Standards Association.
Participants

This document was developed by the IEEE 802.16 Working Group on Broadband Wireless Access, which develops the WirelessMAN® Standard for Wireless Metropolitan Area Networks.

IEEE 802.16 Working Group Officers

Roger B. Marks, Chair
Jose Puthenkulam, Vice Chair
Peiying Zhu, Secretary
Jonathan Labs, Maintenance Task Group Chair
Joseph Schumacher, Chief Technical Editor

Historical information regarding IEEE Std 802.16

The following individuals participated in the IEEE 802.16 working group during various stages of the standard’s development. Since the initial publication, many IEEE standards have added functionality or provided updates to material included in this standard. Included is a historical list of participants who have dedicated their valuable time, energy, and knowledge to the creation of this standard.

The following members of the IEEE 802.16 Working Group on Broadband Wireless Access participated in the Working Group Letter Ballot in which IEEE Std 802.16g-2007 was prepared and finalized for IEEE Ballot:

- Ray Abrishami
- Edward Agis
- Aditya Agrawal
- Siavash Alamouti
- Murat Ali
- Mario Aliotta
- Dov Andelman
- Gordon Antonello
- Eli Avivi
- Phillip Barber
- Kevin Baum
- Rajesh Bhalla
- Yufei Blankenship
- Eckard Bogenfeld
- Achim Brandt
- Thomas Brown
- Dean Chang
- Jae Hwan Chang
- Sungcheol Chang
- Yong Chang
- Naftali Chayat
- Rémi Chayer
- Jennifer Chen
- Yuehua (Lucy) Chen
- Aik Chindapol
- Hua (Mary) Chion
- Jaehee Cho
- Jaeweon Cho
- Kihyoung Cho
- Sejei Cho
- Seokheon Cho
- Hyo-Young-Jin Choi
- Yang-Seok Choi
- Arthur Wang
- Fan Wang
- Guo qiang Wang
- Irving Wang
- Lei Wang
- Stanley Wang
- Mattias Wennstrom
- Alfred Wieczorek
- Geng Wu
- Jun Wu
- Xuyong Wu
- David Xiang
- Ling Xu
- Shanshan Xu
- Hassan Yaghoobi

        6.3.2.3.1 DCD (DL channel descriptor) message .................................... 82
        6.3.2.3.2 DL-MAP (Downlink map) message ........................................ 83
        6.3.2.3.3 UCD (UL channel descriptor) message ................................... 84
        6.3.2.3.4 UL-MAP (UL map) message .................................................... 86
        6.3.2.3.5 RNG-REQ (ranging request) message ...................................... 88
        6.3.2.3.6 RNG-RSP (ranging response) message ...................................... 91
        6.3.2.3.7 REG-REQ (registration request) message ............................... 95
        6.3.2.3.8 REG-RSP (registration response) message ............................ 96
        6.3.2.3.9 Privacy key management (PKM) messages (PKM-REQ/PKM-RSP) 99
        6.3.2.3.10 DSA-REQ message .............................................................. 120
        6.3.2.3.11 DSA-RSP message ................................................................. 121
        6.3.2.3.12 DSA-ACK message ................................................................. 122
        6.3.2.3.13 DSC-REQ (DSC request) message ....................................... 123
        6.3.2.3.14 DSC-RSP (DSC response) message ...................................... 124
        6.3.2.3.15 DSC-ACK (DSC acknowledge) message ............................. 125
        6.3.2.3.16 DSD-REQ message .............................................................. 126
        6.3.2.3.17 DSD-RSP message ................................................................. 127
        6.3.2.3.18 MCA-REQ (multicast polling assignment request) message 128
6.3.3.19 MCA-RSP (multicast polling assignment response) message ........................................ 128
6.3.2.20 DBPC-REQ (DL burst profile change request) message ........................................ 129
6.3.2.21 DBPC-RSP (DL burst profile change response) message ........................................ 129
6.3.2.22 RES-CMD (reset command) message ................................................................. 130
6.3.2.23 SBC-REQ (SS basic capability request) message ............................................... 131
6.3.2.24 SBC-RSP (SS basic capability response) message ............................................ 132
6.3.2.25 CLK-CMP (clock comparison) message ............................................................... 133
6.3.2.26 DREG-CMD (de/reregister command) message .................................................... 134
6.3.2.27 DSX-RVD (DSx received) message ................................................................. 136
6.3.2.28 TFTP-CPLT (Config File TFTP complete) message ........................................ 137
6.3.2.29 TFTP-RSP (Config File TFTP complete response) message ............................... 138
6.3.2.30 ARQ-Feedback message .................................................................................. 138
6.3.2.31 ARQ-Discard message ..................................................................................... 139
6.3.2.32 ARQ-Reset message ......................................................................................... 139
6.3.2.33 Channel Measurement REP-REQ/RSP (report request/response) .................. 140
6.3.2.34 FPC (fast power control) message ...................................................................... 141
6.3.2.35 AAS-FBCK-REQ/RSP (AAS channel feedback request/response) messages .... 142
6.3.2.36 AAS_Beam_Select message ............................................................................. 143
6.3.2.37 DREG-REQ (SS deregistration request) message ............................................ 144
6.3.2.38 HARQ MAP message ...................................................................................... 145
6.3.2.39 MOB_SLP-REQ (sleep request) message .......................................................... 183
6.3.2.40 MOB_SLP-RSP (sleep response) message .......................................................... 186
6.3.2.41 MOB_TRF-IND (traffic indication) message ....................................................... 191
6.3.2.42 MOB_NBR-ADV (neighbor advertisement) message ........................................... 193
6.3.2.43 MOB_SCN-REQ (scanning interval allocation request) message .................. 201
6.3.2.44 MOB_SCN-RSP (scanning interval allocation response) message ............ 204
6.3.2.45 MOB_SCN-REP (scanning result report) message ......................................... 212
6.3.2.46 MOB_ASC-REP (association result report) message ...................................... 218
6.3.2.47 MOB_BSHO-REQ (BS HO request) message .................................................. 221
6.3.2.48 MOB_MSHO-REQ (MS HO request) message ................................................ 232
6.3.2.49 MOB_BSHO-RSP (BS HO response) message .................................................. 236
6.3.2.50 MOB_HO-IND (HO indication) message ............................................................. 247
6.3.2.51 MOB_PAG-ADV (BS broadcast paging) message ............................................ 249
6.3.2.52 MBS_MAP (multicast and broadcast service map) message .......................... 251
6.3.2.53 PMC_REQ (power control mode change request) message ......................... 257
6.3.2.54 PMC_RSP (power control mode change response) message ......................... 258
6.3.2.55 OFDMA SUB-DL-UL-MAP message .............................................................. 260
6.3.2.56 MIMO precoding setup/tear-down messages ................................................... 263
6.3.2.57 MIH Payload Transfer (MOB_MIH-MSG) message ......................................... 264
6.3.2.58 Service Identity Information (SII-ADV) message ........................................... 264
6.3.2.59 Location Based Services (LBS-ADV) message ............................................... 265

6.3.3 Construction and transmission of MAC PDUs ......................................................... 267
6.3.3.1 Conventions ........................................................................................................... 268
6.3.3.2 Concatenation ...................................................................................................... 268
6.3.3.3 Fragmentation ....................................................................................................... 268
6.3.3.3.1 Non-ARQ connections .................................................................................. 269
6.3.3.3.2 ARQ-enabled connections ........................................................................... 269
6.3.3.4 Packing ................................................................................................................ 269
6.3.3.4.1 Packing for non-ARQ connections .................................................................. 269
6.3.3.4.2 Packing for ARQ-enabled connections ......................................................... 271
6.3.3.4.3 Packing ARQ Feedback IEs ........................................................................ 272
6.3.3.5 CRC calculation .................................................................................................. 273
6.3.3.5.1 CRC32 calculation for SC and OFDM mode .............................................. 273
6.3.3.5.2 CRC32 calculation for OFDMA mode ......................................................... 274
6.3.3.6 Encryption of MAC PDUs ................................................................. 274
6.3.3.7 Padding ....................................................................................... 275
6.3.4 ARQ mechanism .............................................................................. 275
6.3.4.1 ARQ block usage ................................................................. 276
6.3.4.2 ARQ Feedback IE format .................................................... 277
6.3.4.2.1 ARQ Feedback IE format with extended capability .......... 279
6.3.4.3 ARQ parameters ................................................................. 283
6.3.4.3.1 ARQ_BSN_MODULUS ......................................................... 283
6.3.4.3.2 ARQ_WINDOW_SIZE ....................................................... 283
6.3.4.3.3 ARQ_BLOCK_LIFETIME ............................................... 283
6.3.4.3.4 ARQ_RETRY_TIMEOUT .................................................... 283
6.3.4.3.5 ARQ_SYNC_LOSS_TIMEOUT ........................................ 283
6.3.4.3.6 ARQ_RX_PURGE_TIMEOUT ........................................... 283
6.3.4.3.7 ARQ_BLOCK_SIZE ........................................................ 284
6.3.4.4 ARQ procedures ........................................................................... 284
6.3.4.4.1 ARQ state machine variables ............................................. 284
6.3.4.5 ARQ-enabled connection setup and negotiation ......................... 284
6.3.4.6 ARQ operation ............................................................................. 284
6.3.4.6.1 Sequence number comparison ........................................... 284
6.3.4.6.2 Transmitter state machine .................................................. 285
6.3.4.6.3 Receiver state machine ....................................................... 289
6.3.5 Scheduling services ......................................................................... 291
6.3.5.1 Outbound transmission scheduling ............................................. 293
6.3.5.2 UL request/grant scheduling ..................................................... 293
6.3.5.2.1 Unsolicited grant service (UGS) ........................................... 293
6.3.5.2.2 Real-time polling service (rtPS) ......................................... 294
6.3.5.2.3 Non-real-time polling service (nrtPS) ................................. 295
6.3.5.2.4 Best effort (BE) service ...................................................... 295
6.3.6 Bandwidth allocation and request mechanisms .................................. 295
6.3.6.1 Requests .................................................................................. 295
6.3.6.2 Grants ...................................................................................... 296
6.3.6.3 Polling ...................................................................................... 296
6.3.6.3.1 Unicast polling ................................................................. 296
6.3.6.3.2 Multicast and broadcast polling ........................................... 298
6.3.6.3.3 PM bit .............................................................................. 300
6.3.6.4 Contention-based focused BRs for WirelessMAN-OFDM ............ 300
6.3.6.5 Contention-based CDMA BRs for WirelessMAN-OFDMA .......... 301
6.3.7 MAC support of PHY ................................................................. 301
6.3.7.1 Frequency division duplexing (FDD) ........................................... 301
6.3.7.2 Time division duplexing (TDD) .................................................. 301
6.3.7.3 DL-MAP message ................................................................. 301
6.3.7.4 UL-MAP message ...................................................................... 302
6.3.7.4.1 UL timing ........................................................................ 303
6.3.7.4.2 UL allocations ................................................................... 303
6.3.7.4.3 UL interval definition ....................................................... 303
6.3.7.5 Map relevance and synchronization .......................................... 304
6.3.7.5.1 WirelessMAN-SC PHY ....................................................... 306
6.3.7.5.2 WirelessMAN-OFDM PHY .............................................. 306
6.3.7.5.3 WirelessMAN-OFDMA PHY ........................................... 306
6.3.7.6 Optional MAC AAS support of OFDM and OFDMA ................... 306
6.3.7.6.1 AAS MAC services ......................................................... 306
6.3.7.6.2 MAC control functions .................................................... 307
6.3.7.6.3 AAS DL synchronization .................................................... 308
6.3.7.6.4 Alerting the BS about presence of a new SS in an AAS system ....... 308

IEEE Standard for
Local and metropolitan area networks
Part 16: Air Interface for Broadband
Wireless Access Systems

IMPORTANT NOTICE: This standard is not intended to ensure safety, security, health, or environmental protection in all circumstances. Implementers of the standard are responsible for determining appropriate safety, security, environmental, and health practices or regulatory requirements.

This IEEE document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading “Important Notice” or “Important Notices and Disclaimers Concerning IEEE Documents.” They can also be obtained on request from IEEE or viewed at http://standards.ieee.org/IPR/disclaimers.html.

1. Overview

1.1 Scope

This standard specifies the air interface, including the medium access control layer (MAC) and physical layer (PHY), of combined fixed and mobile point-to-multipoint broadband wireless access (BWA) systems providing multiple services. The MAC is structured to support multiple PHY specifications, each suited to a particular operational environment.

1.2 Purpose

This standard enables rapid worldwide deployment of innovative, cost-effective, and interoperable multivendor broadband wireless access products, facilitates competition in broadband access by providing alternatives to wireline broadband access, encourages consistent worldwide spectrum allocation, and accelerates the commercialization of broadband wireless access systems.

1.3 Variants and frequency bands

Several conforming variants of this standard are specified. The appropriate variant depends on the radio frequency band in which it operates. The primary bands of interest are described in 1.3.1 through 1.3.3. The variants are listed in 1.3.4.
1.3.1 10–66 GHz licensed bands

The 10–66 GHz bands provide a physical environment where, due to the short wavelength, line-of-sight (LOS) is required and multipath is negligible. In the 10–66 GHz band, channel bandwidths of 25 MHz or 28 MHz are typical. With raw data rates in excess of 120 Mb/s, this environment is well suited for point-to-multipoint (PMP) access serving applications from small office/home office (SOHO) through medium to large office applications.

The single-carrier modulation air interface specified herein for 10–66 GHz shall be known as the “WirelessMAN-SC™” air interface.

1.3.2 Frequencies below 11 GHz

Frequencies below 11 GHz provide a physical environment where, due to the longer wavelength, LOS is not necessary and multipath may be significant. The ability to support near-LOS and non-LOS (NLOS) scenarios requires additional PHY functionality, such as the support of advanced power management techniques, interference mitigation/coexistence, and multiple antennas.

1.3.3 License-exempt frequencies below 11 GHz (primarily 5–6 GHz)

The physical environment for the license-exempt bands below 11 GHz is similar to that of the licensed bands in the same frequency range, as described in 1.3.2. However, the license-exempt nature introduces additional interference and co-existence issues, whereas regulatory constraints limit the allowed radiated power. In addition to the features described in 1.3.2, the PHY and MAC introduce mechanisms to facilitate the detection and avoidance of interference and the prevention of harmful interference into other users including specific spectrum users identified by regulation. This includes a mechanism for regulatory compliance called dynamic frequency selection (DFS).

It is recognized that some administrations require notification of terminal location for certain services in some license-exempt bands, which is a form of licensing. Conversely, it is possible to have uncoordinated usage within a licensed allocation. In these and other similar cases, the pertinent issues for license-exempt usage remain as described in the preceding paragraph.

In the context of this standard, the use of the term “license-exempt frequencies” or “license-exempt bands” should be taken to mean the situation where licensing authorities do not coordinate individual assignments of frequency bands to operators, regardless of whether the spectrum in question has a particular regulatory status as license-exempt or licensed.

1.3.4 Air interface variant nomenclature and compliance

Table 1 summarizes the nomenclature for the various air interface variants in this standard.

All implementations of this standard shall comply with the requirements of Clause 6 and Clause 7.

Implementations of this standard for any applicable frequencies between 10 GHz and 66 GHz shall comply with the WirelessMAN-SC PHY as described in 8.1.

Implementations of this standard for licensed frequencies below 11 GHz (such as those listed in B.1) shall either comply with the WirelessMAN-OFDM PHY as described in 8.3, the WirelessMAN-OFDMA PHY as described in 8.4, or the WirelessMAN-SC PHY as described in 8.1 for licensed frequencies above 10 GHz.

Implementations of this standard for license-exempt frequencies below 11 GHz (such as those listed in B.1) shall comply with the WirelessMAN-OFDM PHY as described in 8.3, or the WirelessMAN-OFDMA PHY as described in 8.4. They shall further comply with the DFS protocols (6.3.15) (where mandated by regulation) and with 8.5.

### 1.4 Reference models

Figure 1 illustrates the reference model and scope of this standard.

The MAC comprises three sublayers. The service-specific convergence sublayer (CS) provides any transformation or mapping of external network data, received through the CS service access point (SAP), into MAC service data units (SDUs) received by the MAC common part sublayer (CPS) through the MAC SAP. This includes classifying external network SDUs and associating them to the proper MAC service flow identifier (SFID) and connection identifier (CID). It may also include such functions as payload header suppression (PHS). Multiple CS specifications are provided for interfacing with various protocols. The internal format of the CS payload is unique to the CS, and the MAC CPS is not required to understand the format of or parse any information from the CS payload.
The MAC CPS provides the core MAC functionality of system access, bandwidth allocation, connection establishment, and connection maintenance. It receives data from the various CSs, through the MAC SAP, classified to particular MAC connections. An example of MAC CPS service definition is given in Annex C. Quality of service (QoS) is applied to the transmission and scheduling of data over the PHY.

The MAC also contains a separate security sublayer providing authentication, secure key exchange, and encryption.

Data, PHY control, and statistics are transferred between the MAC CPS and the PHY via the PHY SAP (which is implementation specific).

The PHY definition includes multiple specifications, each appropriate to a particular frequency range and application. The various PHY specifications supported are discussed in Clause 8.

The IEEE 802.16 devices can include Subscriber Stations (SS) or Mobile Stations (MS), or Base Stations (BS). As the IEEE 802.16 devices may be part of a larger network and therefore would require interfacing with entities for management and control purposes, a Network Control and Management System (NCMS) abstraction has been introduced in this standard as a “black box” containing these entities. The NCMS abstraction allows the PHY/MAC layers specified in IEEE Std 802.16 to be independent of the network architecture, the transport network, and the protocols used at the backend and therefore allows greater flexibility. NCMS logically exists at BS side and SS/MS side of the radio interface, termed NCMS(BS) and NCMS(SS/MS), respectively. Any necessary inter-BS coordination is handled through the NCMS(BS).
This specification includes a Control SAP (C-SAP) and Management SAP (M-SAP) that expose control plane and management plane functions to upper layers. The C_SAP and M-SAP interfaces are described in Clause 14. The NCMS uses the C-SAP and M-SAP to interface with the IEEE 802.16 entity. In order to provide correct MAC operation, NCMS shall be present within each SS/MS. The NCMS is a layer independent entity that may be viewed as a management entity or control entity. General system management entities can perform functions through NCMS and standard management protocols can be implemented in the NCMS.

1.4.1 Management reference model

Figure 2 shows a management reference model of BWA networks. It consists of a network management system (NMS), managed nodes, and a Network Control System. Managed nodes, such as BS, MS and SS, collect and store the managed objects in the format of WirelessMAN Interface MIB (e.g., wmanIfMiB) and Device MIB (e.g., wmanDevMiB) that are made available to NMSs via management protocols, such as Simple Network Management Protocol (SNMP). A Network Control System contains the service flow and the associated QoS information that have to be populated to BS when a SS or MS enters into a BS network.

The management information between SS/MS and BS will be carried over the secondary management connection for managed SS or MS. If the secondary management connection does not exist, the SNMP messages, or other management protocol messages, may go through another interface in the customer premise or on a transport connection over the air interface.

Figure 2—BWA WirelessMAN network management reference model

1.4.2 Handover (HO) process

The HO process in which an MS migrates from the air-interface provided by one BS to the air-interface provided by another BS is defined in 6.3.21.2.

1.4.3 IEEE 802.16 entity

An IEEE 802.16 entity is defined as the logical entity in an SS/MS or BS that comprises the PHY and MAC layers of the Data Plane and the Management/Control Plane.
1.4.4 Network reference model

Figure 3 describes a simplified network reference model. Multiple SS or MS may be attached to a BS. SS or MS communicate to the BS over the U interface using a Primary Management Connection, a Basic Connection, or a Secondary Management Connection.

1.4.4.1 SS/MS and BS Interface

This standard observes the following correlation:

- MAC management PDUs that are exchanged on the basic management connection trigger or are triggered by primitives that are exchanged over the C-SAP.
- MAC management PDUs that are exchanged on the primary management connection trigger or are triggered by primitives that are exchanged over either the C-SAP or the M-SAP depending on the particular management or control operation.
- Messages that are exchanged over the secondary management connection trigger or are triggered by primitives that are exchanged over the M-SAP.

1.4.4.2 IEEE 802.16 entity to NCMS Interface

This interface is a set of SAP between an IEEE 802.16 entity and NCMS and is represented in Figure 3. It is decomposed into two parts: the M-SAP is used for less time sensitive Management plane primitives and the C-SAP is used for more time sensitive Control plane primitives that support handovers, security context management, radio resource management, and low power operations (such as idle mode and paging functions).
1.4.5 Management SAP (M-SAP)

The Management SAP may include, but is not limited to primitives related to the following:

- System configuration
- Monitoring statistics
- Notifications/Triggers
- Multi-mode interface management

The NCMS interacts with the MIB through the M-SAP in a method not defined in this standard.

1.4.6 Control SAP (C-SAP)

The Control SAP may include, but is not limited to primitives related to the following:

- Handovers (e.g., notification of HO request from MS)
- Idle mode mobility management (e.g., Mobile entering idle mode)
- Subscriber and session management (e.g., Mobile requesting session setup)
- Radio resource management
- AAA server signaling (e.g., EAP payloads)
- Media Independent Handover Function Services
- Location detection reporting capability

1.5 Managed objects

The definition of managed objects in this standard is expressed in IETF RFC 2578. It supports a management protocol agnostic approach, including SNMP.

3. Definitions

For the purposes of this standard, the following terms and definitions apply. The Authoritative Dictionary of IEEE Standards Terms [B23] should be referenced for terms not defined in this clause.

3.1 active base station (BS): A BS that is informed of the mobile station (MS) capabilities, security parameters, service flows, and full medium access control layer (MAC) context information. For macro diversity handover (MDHO), the MS transmits/receives data to/from all active BSs in the diversity set.

3.2 adaptive antenna system (AAS): An array of antennas and associated signal processing that together is able to change its antenna radiation pattern dynamically to adjust to noise environment, interference and multipath.

3.3 adaptive modulation: A system’s ability to communicate with another system using multiple burst profiles and a system’s ability to subsequently communicate with multiple systems using different burst profiles.

3.4 adjacent subcarrier allocation: A permutation where the subcarriers are located adjacent to each other.

3.5 anchor base station (BS): For macro diversity handover (MDHO) or fast BS switching (FBSS) supporting mobile stations (MSs), a BS where the MS is registered, is synchronized, performs ranging, and monitors the downlink (DL) for control information. For FBSS supporting MSs, the anchor BS is the serving BS that is designated to transmit/receive data to/from the MS at a given frame.

3.6 Authenticator: Authenticator functionality is part of AAA Services, which is included in the NCMS. An authenticator is an entity at one end of a point-to-point link that facilitates authentication of a supplicant (MS) attached to the other end of that link. It can enforce authentication before allowing access to services that are accessible to the supplicant. The authenticator incorporates an AAA client functionality that enables it to communicate with AAA backend infrastructure (AAA based Authentication Server). The AAA server provides the Authenticator with authentication and authorization services over AAA protocols. The authenticator function contains a Key Distributor and may also include a Key Receiver function.

3.7 automatic repeat request (ARQ) block: A distinct unit of data that is carried on an ARQ-enabled connection. Such a unit is assigned a sequence number and is managed as a distinct entity by the ARQ state machines. Block size is a parameter negotiated during connection establishment.

3.8 backbone network: A communication mechanism by which two or more base stations (BSs) communicate to each other. It may also include communication with other networks. The method of communication for backbone networks is outside the scope of this standard.

3.9 bandwidth stealing: The use, by a subscriber station (SS), of a portion of the bandwidth allocated in response to a bandwidth request (BR) for a connection to send a BR or data for any of its connections.

NOTE—See also 6.3.6.

3.10 base station (BS): A generalized equipment set providing connectivity, management, and control of the subscriber station (SS). See also: active base station (BS), anchor base station (BS), neighbor base station (BS), serving base station (BS), target base station (BS).

---

11The numbers in brackets correspond to the numbers of the bibliography in Annex A.
12Notes in text, tables, and figures are given for information only and do not contain requirements needed to implement this standard.
3.11 base station (BS) receive/transmit transition gap (RTG): A gap between the last sample of the uplink (UL) burst and the first sample of the subsequent downlink (DL) burst at the antenna port of the BS in a time division duplex (TDD) transceiver. This gap allows time for the BS to switch from receive (Rx) to transmit (Tx) mode. During this gap, the BS is not transmitting modulated data but simply allowing the BS transmitter carrier to ramp up and the Tx/Rx antenna switch to actuate. Not applicable for frequency division duplex (FDD) systems.

3.12 base station (BS) transmit/receive transition gap (TTG): A gap between the last sample of the downlink (DL) burst and the first sample of the subsequent uplink (UL) burst at the antenna port of the BS in a time division duplex (TDD) transceiver. This gap allows time for the BS to switch from transmit (Tx) to receive (Rx) mode. During this gap, the BS is not transmitting modulated data but simply allowing the BS transmitter carrier to ramp down, the Tx/Rx antenna switch to actuate, and the BS receiver section to activate. Not applicable for frequency division duplex (FDD) systems.

3.13 basic connection: Connection that is established during subscriber station (SS) initial ranging and used to transport delay-intolerant medium access control layer (MAC) management messages.

3.14 broadband: Having instantaneous bandwidths greater than around 1 MHz and supporting data rates greater than about 1.5 Mb/s.

3.15 broadband wireless access (BWA): Wireless access in which the connection(s) capabilities are broadband.

3.16 broadcast connection: The management connection used by the base station (BS) to send medium access control layer (MAC) management messages on a downlink (DL) to all subscriber stations (SSs). The broadcast connection is identified by a well-known connection identifier (CID). A fragmentable broadcast connection is a connection that allows fragmentation of broadcast MAC management messages.

NOTE—See Table 558.

3.17 burst profile: Set of parameters that describe the uplink (UL) or downlink (DL) transmission properties associated with an interval usage code. Each profile contains parameters such as modulation type, forward error correction (FEC) type, preamble length, guard times, etc. See also: interval usage code.

3.18 channel identifier (ChID): An identifier used to distinguish between multiple uplink (UL) channels, all of which are associated with the same downlink (DL) channel.

3.19 concatenation: The act of combining multiple medium access control layer (MAC) protocol data units (PDUs) into a single physical layer (PHY) service data unit (SDU).

3.20 connection: A unidirectional mapping between base station (BS) and subscriber station (SS) medium access control layer (MAC) peers. Connections are identified by a connection identifier (CID). The MAC defines two kinds of connections: management connections and transport connections. See also: connection identifier (CID).

3.21 connection identifier (CID): A 16-bit value that identifies a transport connection or an uplink (UL)/downlink (DL) pair of associated management connections [i.e., belonging to the same subscriber station (SS)] to equivalent peers in the medium access control layer (MAC) of the base station (BS) and SS. The CID address space is common (i.e., shared) between UL and DL and partitioned among the different types of connections. Security associations (SAs) also exist between keying material and CIDs. See also: connection.

NOTE—Table 558 specifies how the CID address space is partitioned among the different types of connections.
3.22 DC subcarrier: In an orthogonal frequency division multiplexing (OFDM) or orthogonal frequency division multiple access (OFDMA) signal, the subcarrier whose frequency would be equal to the radio frequency (RF) center frequency of the station.

3.23 diversity set: A list of active base stations (BSs) to the mobile station (MS). The diversity set is managed by the MS and BSs and is applicable to macro diversity handover (MDHO) and fast BS switching (FBSS).

3.24 downlink (DL): The direction from the base station (BS) to the subscriber station (SS).

3.25 downlink burst transition gap (DLBTG): The gap included on the trailing edge of each allocated downlink (DL) burst so that ramp-down can occur and delay-spread can clear receivers.

3.26 downlink channel descriptor (DCD): A medium access control layer (MAC) message that describes the physical layer (PHY) characteristics of a downlink (DL) channel.

3.27 downlink interval usage code (DIUC): An interval usage code specific to a downlink (DL). See also: interval usage code.

3.28 downlink map (DL-MAP): A medium access control layer (MAC) message that defines burst start times for both time division multiple and time division multiple access (TDMA) by a subscriber station (SS) on the downlink (DL).

3.29 dynamic frequency selection (DFS): The ability of a system to switch to different physical radio frequency (RF) channels based on channel measurement criteria to conform to particular regulatory requirements.

3.30 dynamic service: The set of messages and protocols that allow the base station (BS) and subscriber station (SS) to add, modify, or delete the characteristics of a service flow.

3.31 fast base station switching (FBSS): Base station (BS) switching that utilizes a fast switching mechanism to improve link quality. The mobile station (MS) is only transmitting/receiving data to/from one of the active BSs (anchor BS) at any given frame. The anchor BS can change from frame to frame depending on the BS selection scheme.

3.32 fixed wireless access: Wireless access application in which the locations of the base station (BS) and subscriber station (SS) are fixed in location during operation.

3.33 frame: A structured data sequence of fixed duration used by some physical layer (PHY) specifications. A frame may contain both an uplink (UL) subframe and a downlink (DL) subframe.

3.34 frequency assignment (FA): A logical assignment of downlink (DL) center frequency and channel bandwidth programmed to the base station (BS).

3.35 frequency assignment (FA) index: A network-specific logical FA index assignment. FA index assignment is used in combination with operator-specific configuration information provided to the mobile station (MS) in a method outside the scope of this standard.

3.36 frequency division duplex (FDD): A duplex scheme in which uplink (UL) and downlink (DL) transmissions use different frequencies but are typically simultaneous.

3.37 frequency offset index: An index number identifying a particular subcarrier in an orthogonal frequency division multiplexing (OFDM) or orthogonal frequency division multiple access (OFDMA) signal, which is related to its subcarrier index. Frequency offset indices may be positive or negative.
3.38 **group key encryption key (GKEK):** A random number generated by the base station (BS) or a network entity [e.g., an authentication and service authorization (ASA) server] used to encrypt the group traffic encryption keys (GTEKs) sent in broadcast messages by the BS to mobile stations (MSs) in the same multicast group.

3.39 **handover (HO):** The process in which a mobile station (MS) migrates from the air-interface provided by one base station (BS) to the air-interface provided by another BS. A break-before-make HO is where service with the target BS starts after a disconnection of service with the previous serving BS. A make-before-break HO is where service with the target BS starts before disconnection of the service with the previous serving BS.

3.40 **initial ranging connection:** A management connection used by the subscriber station (SS) and the base station (BS) during the initial ranging process. The initial ranging connection is identified by a well-known connection identifier (CID). This CID is defined as a constant value within the protocol since an SS has no addressing information available until the initial ranging process is complete.

NOTE—See Table 558.

3.41 **interval usage code:** A code identifying a particular burst profile that can be used by a downlink (DL) or uplink (UL) transmission interval.

3.42 **Location Based Services (LBS):** Services that are based on location data of the MS and/or BS in a network of IEEE 802.16 devices. Examples in location sensitized applications, emergency call origination tracking, equipment tracking etc.

3.43 **macro diversity handover (MDHO):** The process in which an mobile station (MS) migrates from the air-interface provided by one or more base stations (BSs) to the air-interface provided by one or more other BSs. This process is accomplished in the downlink (DL) by having two or more BSs transmitting the same medium access control layer (MAC) or physical layer (PHY) protocol data unit (PDU) to the MS so that diversity combining can be performed by the MS. In the uplink (UL), it is accomplished by having two or more BSs receiving (demodulating, decoding) the same PDU from the MS so that diversity combining of the received PDU can be performed among the BSs.

3.44 **management connection:** A connection used for transporting medium access control layer (MAC) management messages or standards-based messages required by the MAC. For MAC management messages, see also: basic connection, primary management connection, broadcast connection, initial ranging connection. For standards-based messages required by the MAC, see also: secondary management connection.

NOTE—Table 38 specifies which MAC management message is transmitted on which of the management connections.

3.45 **minislot:** A unit of uplink (UL) bandwidth allocation equivalent to \( n \) physical slots (PSs), where \( n = 2^m \) and \( m \) is an integer ranging from 0 through 7.

3.46 **mobile station (MS):** A station in the mobile service intended to be used while in motion or during halts at unspecified points. An MS is always a subscriber station (SS) unless specifically excepted otherwise in this standard.

3.47 **multicast polling group:** A group of zero or more subscriber stations (SSs) that are assigned a multicast address for the purposes of polling.

3.48 **multiple input multiple output (MIMO):** A system employing at least two transmit (Tx) antennas and at least two receive (Rx) antennas to improve the system capacity, coverage, or throughput.
3.49 **neighbor base station (BS):** For any mobile station (MS), a BS (other than the serving BS) whose downlink (DL) transmission can be received by the MS.

3.50 **Operator ID:** Operator ID is an identifier of the network provider. The Operator ID is contained in the Base Station ID.

3.51 **orderly power-down procedure:** The procedure that the mobile station (MS) performs when powering down, for example, as directed by user input or as prompted by a automatic power-down mechanism.

3.52 **packing:** The act of combining multiple service data units (SDUs) from a higher layer into a single medium access control layer (MAC) protocol data unit (PDU).

3.53 **Paging Controller:** Paging controller is a unit that belongs to the idle mode services in the NCMS. The paging controller retains the MS state and operational parameters and/or administers paging activity for the MS while in idle mode.

3.54 **payload header suppression (PHS):** The process of suppressing the repetitive portion of payload headers at the sender and restoring the headers at the receiver.

3.55 **Payload Header Suppression field (PHSF):** A string of bytes representing the header portion of a protocol data unit (PDU) in which one or more bytes are to be suppressed (i.e., a snapshot of the uncompressed PDU header inclusive of suppressed and unsuppressed bytes).

3.56 **payload header suppression index (PHSI):** An 8-bit value that references the payload header suppression (PHS) rule.

3.57 **payload header suppression mask (PHSM):** A bit mask indicating which bytes in the Payload Header Suppression field (PHSF) to suppress and which bytes to not suppress.

3.58 **payload header suppression size (PHSS):** The length of the suppressed field in bytes. This value is equivalent to the number of bytes in the Payload Header Suppression field (PHSF) and also the number of valid bits in the payload header suppression mask (PHSM).

3.59 **payload header suppression valid (PHSV):** A flag that tells the sending entity to verify all bytes that are to be suppressed.

3.60 **physical slot (PS):** A unit of time, dependent on the physical layer (PHY) specification, for allocating bandwidth.

3.61 **point-to-point (PtP):** A mode of operation whereby a link exists between two network entities.

3.62 **primary management connection:** A connection that is established during initial subscriber station (SS) ranging and used to transport delay-tolerant medium access control layer (MAC) management messages.

3.63 **Privacy Key Management (PKM) Protocol:** A client/server model between the base station (BS) and subscriber station (SS) that is used to secure distribution of keying material.
**3.64 protocol data unit (PDU):** The data unit exchanged between peer entities of the same protocol layer. On the downward direction, it is the data unit generated for the next lower layer. On the upward direction, it is the data unit received from the previous lower layer (see Figure 4).

![Figure 4—PDU and SDU in a protocol stack](image)

**3.65 quality of service (QoS) parameter set:** A parameter set associated with a service flow identifier (SFID). The contained traffic parameters define scheduling behavior of uplink (UL) or downlink (DL) flows associated with transport connections.

NOTE—See 6.3.14.1.

**3.66 radio frequency (RF) center frequency:** The center of the frequency band in which a base station (BS) or subscriber station (SS) is intended to transmit.

**3.67 scanning interval:** A time period intended for the mobile station (MS) to monitor neighbor base stations (BSs) to determine the suitability of the BSs as targets for handover (HO).

**3.68 secondary management connection:** A connection that may be established during subscriber station (SS) registration that is used to transport standards-based [e.g., Simple Network Management Protocol (SNMP), Dynamic Host Configuration Protocol (DHCP)] messages.

**3.69 security association (SA):** The set of security information that a base station (BS) and one or more of its client subscriber stations (SSs) share in order to support secure communications. This shared information includes traffic encryption keys (TEKs) and cipher block chaining (CBC) initialization vectors (IVs).

**3.70 security association identifier (SAID):** An identifier shared between the base station (BS) and subscriber station (SS) that uniquely identifies a security association (SA). The SAID is unique within MS. The uniqueness of this identifier shall be guaranteed by {MS MAC Address, SAID} pair.
3.71 **service access point (SAP):** The point in a protocol stack where the services of a lower layer are available to its next higher layer.

3.72 **service data unit (SDU):** The data unit exchanged between two adjacent protocol layers. On the downward direction, it is the data unit received from the previous higher layer. On the upward direction, it is the data unit sent to the next higher layer.

NOTE—See Figure 4.

3.73 **service flow (SF):** A unidirectional flow of medium access control layer (MAC) service data units (SDUs) on a connection that is provided a particular quality of service (QoS).

3.74 **service flow identifier (SFID):** A 32-bit quantity that uniquely identifies a service flow to the subscriber station (SS).

3.75 **serving base station (BS):** For any mobile station (MS), the BS with which the MS has most recently completed registration at initial network-entry or during a handover (HO).

3.76 **STC layer:** OFDMA Space Time Coding information-flow fed to the STC encoder as an input. The number of STC layers in a system with vertical encoding is one, while in horizontal encoding, it depends on the number of encoding/modulation paths. This term may be used interchangeably with the word _layer_ when used in the context of OFDMA STC.

3.77 **STC stream:** OFDMA Space Time Coding information path encoded by the STC encoder that is passed to subcarrier mapping and sent through one antenna, or passed on to the beamformer. The number of STC streams in both vertical and horizontal encoding systems is the same as the number of output paths of the STC encoder. This term may be used interchangeably with the word _stream_ when used in the context of OFDMA STC.

3.78 **subcarrier index:** An index number identifying a particular used subcarrier in an orthogonal frequency division multiplexing (OFDM) or orthogonal frequency division multiple access (OFDMA) signal. Subcarrier indices are greater than or equal to zero.

3.79 **subscriber station (SS):** A generalized equipment set providing connectivity between subscriber equipment and a base station (BS).

3.80 **subscriber station receive/transmit gap (SSRTG):** The minimum receive-to-transmit turnaround gap. SSRTG is measured from the time of the last sample of the received burst to the first sample of the transmitted burst at the antenna port of the SS.

3.81 **subscriber station transmit/receive gap (SSTTG):** The minimum transmit-to-receive turnaround gap. SSTTG is measured from the time of the last sample of the transmitted burst to the first sample of the received burst at the antenna port of the SS.

3.82 **target base station (BS):** The BS with which a mobile station (MS) intends to be registered at the end of a handover (HO).

3.83 **time division duplex (TDD):** A duplex scheme where uplink (UL) and downlink (DL) transmissions occur at different times but may share the same frequency.

3.84 **time division multiple access (TDMA) burst:** A contiguous portion of the uplink (UL) or downlink (DL) using physical layer (PHY) parameters, determined by the downlink interval usage code (DIUC) or uplink interval usage code (UIUC), that remain constant for the duration of the burst. TDMA bursts are
separated by preambles and are separated by gaps in transmission if subsequent bursts are from different transmitters.

### 3.85 Time Division Multiplexing (TDM) Burst
A contiguous portion of a TDM data stream using physical layer (PHY) parameters, determined by the downlink interval usage code (DIUC), that remain constant for the duration of the burst. TDM bursts are not separated by gaps or preambles.

### 3.86 Transport Connection
A connection used to transport user data. It does not include any traffic over the basic, primary, or secondary management connections. A fragmentable transport connection is a connection that allows fragmentation of service data units (SDUs).

### 3.87 Transport Connection Identifier (CID)
A unique identifier taken from the CID address space that uniquely identifies the transport connection. All user data traffic is carried on transport connections, even for service flows that implement connectionless protocols, such as Internet Protocol (IP). An active or admitted service flow [identified by a service flow identifier (SFID)] maps to a Transport CID assigned by the base station (BS).

### 3.88 Turbo Decoding
Iterative decoding, using soft inputs and soft outputs.

### 3.89 Type/Length/Value (TLV)
A formatting scheme that adds a tag to each transmitted parameter containing the parameter type (and implicitly its encoding rules) and the length of the encoded parameter.

### 3.90 U Interface
The management and control interface that exists between the SS and the BS over the air interface.

### 3.91 Uplink (UL)
The direction from a subscriber station (SS) to the base station (BS).

### 3.92 Uplink Channel Descriptor (UCD)
A medium access control layer (MAC) message that describes the physical layer (PHY) characteristics of an uplink (UL).

### 3.93 Uplink Interval Usage Code (UIUC)
An interval usage code specific to an uplink (UL).

### 3.94 Uplink Map (UL-MAP)
A set of information that defines the entire access for a scheduling interval.

### 3.95 User Data
Protocol data units (PDUs) of any protocol above a service-specific convergence sublayer (CS) received over the CS service access point (SAP).

### 3.96 Wireless Access
End-user radio connection(s) to core networks.

5. Service-specific CS

The service-specific CS resides on top of the MAC CPS and utilizes, via the MAC SAP, the services provided by the MAC CPS (see Figure 1). The CS performs the following functions:

- Accepting higher layer protocol data units (PDUs) from the higher layer
- Performing classification of higher layer PDUs
- Processing (if required) the higher layer PDUs based on the classification
- Delivering CS PDUs to the appropriate MAC SAP
- Receiving CS PDUs from the peer entity

Currently, three CS specifications are provided: the asynchronous transfer mode (ATM) CS, the packet CS, and the Generic Packet CS. Other CSs may be specified in the future.

5.1 ATM CS

The ATM CS is a logical interface that associates different ATM services with the MAC CPS SAP. The ATM CS accepts ATM cells from the ATM layer, performs classification and, if provisioned, PHS, and delivers CS PDUs to the appropriate MAC SAP.

5.1.1 CS service definition

The ATM CS is specifically defined to support the convergence of PDUs generated by the ATM layer protocol of an ATM network. Since ATM cell streams are generated according to the ATM standards, no ATM CS service primitive is required.

5.1.2 Data/Control plane

5.1.2.1 PDU formats

The ATM CS PDU shall consist of an ATM CS PDU header, defined in Table 2, and the ATM CS PDU payload. The ATM CS PDU payload shall be equal to the ATM cell payload. The ATM CS PDU is illustrated in Figure 5.
5.1.2.2 Classification

An ATM connection, which is uniquely identified by a pair of values of virtual path identifier (VPI) and virtual channel identifier (VCI), is either virtual path (VP) switched or virtual channel (VC) switched. In VP-switched mode, all VCIs within one single incoming VPI are automatically mapped to that of an outgoing VPI. In VC-switched mode, input VPI/VCI values are individually mapped to output VPI/VCI values. Thus, when performing PHS, the ATM CS differentiates these two types of connections and performs the suppression accordingly.

A classification rule is a set of matching criteria applied to each ATM cell entering the ATM CS. It consists of some ATM cell matching criteria, such as VPI and VCI, and a reference to a CID. If an ATM cell matches the specified matching criteria, it is delivered to the MAC SAP for delivery on the connection identified by the CID.

ATM CS PDU Payload (48 bytes)

Figure 5—ATM CS PDU format
5.1.2.2.1 VP-switched mode

For VP-switched mode, the VPI field, 12 bits for a network-to-network interface (NNI) or 8 bits for a user-to-network interface (UNI), is mapped to the 16-bit CID for the MAC connection on which it is transported. Since the QoS and category of service parameters for the connection are set at connection establishment, this mapping of VPI to CID guarantees the correct handling of the traffic by the MAC.

5.1.2.2.2 VC-switched mode

For VC-switched mode, the VPI and VCI fields, 28 bits total for an NNI or 24 bits total for a UNI, are mapped to the 16-bit CID for the MAC connection on which it is transported. Since the QoS and category of service parameters for the connection are set at connection establishment, this mapping of VPI and VCI to CID guarantees the correct handling of the traffic by the MAC. Note that the full range of VPI/VCI combinations (up to $2^{28}$ for NNI and $2^{24}$ for UNI) cannot be simultaneously supported in this mode.

5.1.2.3 PHS

In PHS, a repetitive portion of the payload headers of the CS SDUs is suppressed by the sending entity and restored by the receiving entity. On the downlink (DL), the sending entity is the ATM CS on the BS and the receiving entity is the ATM CS on the SS. On the uplink (UL), the sending entity is the ATM CS on the SS, and the receiving entity is the ATM CS on the BS. To further save bandwidth, multiple ATM cells (with or without PHS) that share the same CID may be packed and carried by a single MAC CPS PDU. Note that when PHS is turned off, no part of any ATM cell header including HEC (header error check) field shall be suppressed. This provides an option for protecting the integrity of the cell header. Whether PHS is applied to an ATM connection is signaled in the dynamic service addition (DSA) request (DSA-REQ) message at the connection’s creation. Similarly, the VPI (for VP-switched connections) or the VPI/VCI (for VC-switched connections) is also signaled in the classification rule settings of the DSA-REQ message at connection creation.

5.1.2.3.1 PHS for VP-switched ATM connections

In VP-switched mode, the VPI is mapped to a CID. This allows the disposal of the remainder of the ATM cell header except for the VCI, PTI (payload type indicator), and CLP (cell loss priority) fields. These fields shall be encapsulated in the CS PDU header.

Figure 6 shows a CS PDU containing a single VP-switched ATM cell with the cell header suppressed and the format of the ATM CS PDU header for VP-switched ATM connections.

![Figure 6—CS PDU format for VP-switched ATM connections](image-url)
5.1.2.3.2 PHS for VC-switched ATM connections

In VC-switched mode, the VPI/VCI combination is mapped to a CID. This allows the disposal of the remainder of the ATM cell header except for the PTI and CLP fields. These fields shall be encapsulated in the CS PDU header.

Figure 7 shows a CS PDU containing a single VC-switched ATM cell with the cell header suppressed and the format of the ATM CS PDU header for VC-switched ATM connections.

![Figure 7—CS PDU format for VC-switched ATM connections](image)

5.1.2.4 Signaling procedure

ATM interfaces support three types of connections, switched virtual circuit (SVC), permanent virtual circuit (PVC), and soft PVC. SVCs are established and terminated dynamically on demand by the use of signaling. The word “permanent” signifies that the circuit is established administratively. Although both PVC and soft PVC are established administratively, PVCs are established by provisioning process, and soft PVCs are established by the use of signaling.

ATM networks use common channel signaling (CCS), where signaling messages are carried over a connection completely independent of user connections and where one signaling channel can carry signaling messages for a number of user connections. With nonassociated signaling (ATM as-sig-0061.000), by default, the signaling channel on VPI = 0 controls all VPs on the same physical interface. In other words, except when the optional proxy signaling capability (Annex 2 of ATM as-sig-0061.000) or when the optional Virtual UNI capability (Annex 8 of ATM as-sig-0061.000) is used, the signaling channel is identified by VPI = 0 and VCI = 5. Note that this specification does not support associated signaling (ATM af-unii-0010.002), where VCI = 5 of each VP is used as the signaling channel for all VCs on the same VP. In addition, this specification does not support either proxy signaling or virtual UNI.

To establish an SVC, it is the responsibility of the calling party to initiate the signaling procedure by issuing the appropriate signaling messages. Either end can establish or release the SVC. Details on how to use these signaling messages are available in ATM as-sig-0061.000. It shall be the responsibility of the implementation of the BS to map ATM signaling messages to corresponding MAC CPS service primitives.

To establish a soft PVC, the network management system provisions one end of the soft PVC with the address identifying the egress ATM interface of the ATM network. The calling end has the responsibility for establishing and releasing the connection. It is also the responsibility of the calling party (if necessary) to reestablish the connection in case of switching system or link failure. It shall be the responsibility of the implementation of the BS to map ATM signaling messages to corresponding MAC CPS service primitives.

On the DL direction, the signaling starts at an “end user” of the ATM backhaul network that implements an ATM UNI and terminates at the BS that shall implement either an ATM UNI or an ATM NNI. The signaling may be mapped by an interworking function (IWF) and extended to some user network on the SS-side. On
the UL direction, the signaling starts at the ATM interface of the BS and ends at the ATM UNI of an “end user.” In addition, the signaling may be originated by an “end user” of some user network and mapped by the IWF. Note that mapping of data units carried by the air link shall be limited to only cell-level convergence (5.1.2.2). If required by a user network, other levels of mappings (e.g., the convergence of, say, an Ethernet packet to ATM cells) shall be handled by the user network’s IWF exclusively.

During the provisioning process, each SS joining the IEEE 802.16 system shall request a dedicated CID as the signaling connection corresponding to the CCS connection used by ATM networks. Any CID provisioned for this purpose shall not be dynamically changed or terminated. Each IEEE 802.16 system shall provision a set of CIDs for this purpose.

5.2 Packet CS

The packet CS resides on top of the IEEE 802.16 MAC CPS. The CS performs the following functions, utilizing the services of the MAC:

a) Classification of the higher layer protocol PDU into the appropriate transport connection
b) Suppression of payload header information (optional)
c) Delivery of the resulting CS PDU to the MAC SAP associated with the service flow for transport to the peer MAC SAP
d) Receipt of the CS PDU from the peer MAC SAP
e) Rebuilding of any suppressed payload header information (optional)

The sending CS is responsible for delivering the MAC service data unit (MAC SDU) to the MAC SAP. The MAC is responsible for delivery of the MAC SDU to peer MAC SAP in accordance with the QoS, fragmentation, concatenation, and other transport functions associated with a particular connection’s service flow characteristics. The receiving CS is responsible for accepting the MAC SDU from the peer MAC SAP and delivering it to a higher layer entity.

The packet CS is used for transport for all packet-based protocols as defined in 11.13.18.3.

5.2.1 MAC SDU format

Once classified and associated with a specific MAC connection, higher layer PDUs shall be encapsulated in the MAC SDU format as illustrated in Figure 8. The 8-bit PHSI (payload header suppression index) field shall be present when a PHS rule has been defined for the associated connection.

PHS is described in 5.2.3.
5.2.2 Classification

Classification is the process by which a MAC SDU is mapped onto a particular transport connection for transmission between MAC peers. The mapping process associates a MAC SDU with a transport connection, which also creates an association with the service flow characteristics of that connection. This process facilitates the delivery of MAC SDUs with the appropriate QoS constraints.

A classification rule is a set of matching criteria applied to each packet entering the IEEE 802.16 network. It consists of some protocol-specific packet matching criteria (destination IP address, for example), a classification rule priority, and a reference to a CID. If a packet matches the specified packet matching criteria, it is then delivered to the SAP for delivery on the connection defined by the CID. Implementation of each specific classification capability (as, for example, IPv4 based classification) is optional. The service flow characteristics of the connection provide the QoS for that packet.

Several classification rules may each refer to the same service flow. The classification rule priority is used for ordering the application of classification rules to packets. Explicit ordering is necessary because the patterns used by classification rules may overlap. The priority need not be unique, but care shall be taken within a classification rule priority to prevent ambiguity in classification. DL classification rules are applied by the BS to packets it is transmitting and UL classification rules are applied at the SS. Figure 9 and Figure 10 illustrate the mappings discussed in the previous paragraph.

It is possible for a packet to fail to match the set of defined classification rules. In this case, the CS shall discard the packet.

![Diagram](image-url)
5.2.3 Payload header suppression (PHS)

In PHS, a repetitive portion of the payload headers of the higher layer is suppressed in the MAC SDU by the sending entity and restored by the receiving entity. Implementation of PHS capability is optional. On the UL, the sending entity is the SS and the receiving entity is the BS. On the DL, the sending entity is the BS and the receiving entity is the SS. If PHS is enabled at MAC connection, each MAC SDU is prefixed with a PHSI, which references the Payload Header Suppression field (PHSF).

The sending entity uses classification rules to map packets into a service flow. The classification rule uniquely maps packets to its associated PHS Rule. The receiving entity uses the CID and the PHSI to restore the PHSF. Once a PHSF has been assigned to a PHSI, it shall not be changed. To change the value of a PHSF on a service flow, a new PHS rule shall be defined, the old rule is removed from the service flow, and the new rule is added. When all classification rules associated with the PHS rule are deleted, then the PHS rule shall also be deleted.

PHS has a payload header suppression valid (PHSV) option to verify or not verify the payload header before suppressing it. PHS has also a payload header suppression mask (PHSM) option to allow select bytes not to be suppressed. The PHSM facilitates suppression of header fields that remain static within a higher layer session (e.g., IP addresses), while enabling transmission of fields that change from packet to packet (e.g., IP Total Length).

The BS shall assign all PHSI values just as it assigns all CID values. Either the sending or the receiving entity shall specify the PHSF and the payload header suppression size (PHSS). This provision allows for preconfigured headers or for higher level signaling protocols outside the scope of this standard to establish cache entries.

It is the responsibility of the higher layer service entity to generate a PHS Rule that uniquely identifies the suppressed header within the service flow. It is also the responsibility of the higher layer service entity to
guarantee that the byte strings that are being suppressed are constant from packet to packet for the duration of the active service flow.

5.2.3.1 PHS operation

SS and BS implementations are free to implement PHS in any manner as long as the protocol specified in this subclause is followed. Figure 11 illustrates the following procedure.

A packet is submitted to the packet CS. The SS applies its list of classification rules. A match of the rule shall result in an UL service flow and CID and may result in a PHS Rule. The PHS Rule provides PHSF, PHSI, PHSM, PHSS, and PHSV. If PHSV is set or not present, the SS shall compare the bytes in the packet header with the bytes in the PHSF that are to be suppressed as indicated by the PHSM. If they match, the SS shall suppress all the bytes in the UL PHSF except the bytes masked by PHSM. The SS shall then prefix the PDU with the PHSI and present the entire MAC SDU to the MAC SAP for transport on the UL.

When the MAC protocol data unit (MAC PDU) is received by the BS from the air interface, the BS MAC shall determine the associated CID by examination of the generic MAC header. The BS MAC sends the PDU to the MAC SAP associated with that CID. The receiving packet CS uses the CID and the PHSI to look up PHSF, PHSM, and PHSS. The BS reassembles the packet and then proceeds with normal packet processing. The reassembled packet contains bytes from the PHSF. If verification was enabled, then the PHSF bytes equal the original header bytes. If verification was not enabled, then there is no guarantee that the PHSF bytes match the original header bytes.

A similar operation occurs on the DL. The BS applies its list of Classifiers classification rules. A match of the classification shall result in a DL service flow and a PHS rule. The PHS rule provides PHSF, PHSI, PHSM, PHSS, and PHSV. If PHSV is set or not present, the BS shall verify the Downlink Suppression field in the packet with the PHSF. If they match, the BS shall suppress all the bytes in the Downlink Suppression field except the bytes masked by PHSM. The BS shall then prefix the PDU with the PHSI and present the entire MAC SDU to the MAC SAP for transport on the DL.

The SS shall receive the packet based upon the CID Address filtering within the MAC. The SS receives the PDU and then sends it to the CS. The CS then uses the PHSI and CID to lookup PHSF, PHSM, and PHSS. The SS reassembles the packet and then proceeds with normal packet processing.

Figure 12 demonstrates packet suppression and restoration when using PHS masking. Masking allows only bytes that do not change to be suppressed. Note that the PHSF and PHSS span the entire suppression field, included suppressed and unsuppressed bytes.
Figure 11—PHS operation
5.2.3.2 PHS signaling

PHS requires the creation of the following three objects:

a) Service flow
b) Classification rule
c) PHS rule

These three objects may be created either simultaneously or in separate message flows.

PHS rules are created with DSA or dynamic service change (DSC) messages. The BS shall define the PHSI when the PHS Rule is created. PHS rules are deleted with the DSC or dynamic service deletion (DSD) messages. The SS or BS may define the PHSS and PHSF. To change the value of a PHSF on a service flow, a new PHS rule shall be defined, the old rule is removed from the service flow, and the new rule is added.

Figure 13 shows the two ways to signal the creation of a PHS rule.

It is possible to partially specify a PHS rule (in particular the size of the rule) at the time a service flow is created. As an example, it is likely that when a service flow is first provisioned, the header fields to be suppressed will be known. The values of some of the fields [for example: IP addresses, User Datagram Protocol (UDP) port numbers, etc.] may be unknown and would be provided in a subsequent DSC as part of the activation of the service flow (using the “Set PHS Rule” DSC Action). If the PHS rule is being defined in more than one step, each step, whether it is a DSA or DSC message, shall contain both the SFID (or reference) and a PHS index to uniquely identify the PHS rule that is being defined.
5.2.4 IEEE 802.3/Ethernet-specific part

5.2.4.1 IEEE 802.3/Ethernet CS PDU format

The IEEE 802.3/Ethernet PDUs are mapped to MAC SDUs according to Figure 14 (when header suppression is enabled at the connection, but not applied to the CS PDU) or Figure 15 (with header suppression). In the case where PHS is not enabled, PHSI field shall be omitted.

The IEEE 802.3/Ethernet PDU shall not include the Ethernet FCS when transmitted over this CS.

ROHC (refer to IETF RFC 3095) may be used in addition to PHS to compress the IP header portion of an IP packet over Ethernet frame. The MS and the BS shall set bit 7 of Request/Transmission Policy (see 11.13.11) to 0 to enable ROHC. When ROHC is enabled for a service flow, the service flow constitutes what in RFC 3095 is referred to as a ROHC channel. Two service flows cannot share a ROHC channel, and two ROHC channels cannot share the same service flow. On a service flow for which ROHC has been enabled, all of the IP packet parts of IP over Ethernet frames shall pass through the ROHC compressor on the sender side and the decompressor on the receiver side.
ROHC compression and decompression operation shall be performed in accordance with RFC 3095, RFC 3759, RFC 3243, RFC 4995, RFC 3843, RFC 4996. To enable ROHC, the following two steps are required:

1) Capability negotiation during REG-REQ/RSP message exchange to determine whether ROHC is supported.

2) Indication in DSA-REQ/RSP messages to enable ROHC for the service flow.

5.2.4.2 IEEE 802.3/Ethernet CS classification rules

The following parameters are relevant for IEEE 802.3/Ethernet CS classification rules:

- IEEE 802.3/Ethernet header classification parameters—zero or more of the IEEE 802.3/Ethernet, VLAN and IP headers may be included in the classification. In this case, only the IEEE 802.3/IEEE 802.1Q/IP (11.13.18.3.3.2 through 11.13.18.3.3.12 and 11.13.18.3.3.16) classification parameters are allowed.
- For IP over IEEE 802.3/Ethernet, Ethernet, and VLAN, IP headers may be included in classification. In this case, only the IP, IEEE 802.3 and IEEE 802.1Q (11.13.18.3.3.2 through 11.13.18.3.3.12 and 11.13.18.3.3.16) classification parameters are allowed.
- For IP-header compressed IP over IEEE 802.3/Ethernet, Ethernet and VLAN headers may be included in the classification. In this case, only the IEEE 802.3/IEEE 802.1Q (11.13.18.3.3.8 through 11.13.18.3.3.12) classification parameters are allowed.

5.2.5 IP specific part

This subclause applies when IP (IETF RFC 791 and IETF RFC 2460) is carried over the IEEE 802.16 network.

5.2.5.1 IP CS PDU format

The format of the IP CS PDU shall be as shown in Figure 16 (when header suppression is enabled at the connection, but not applied to the CS PDU) or Figure 17 (with header suppression). In the case where PHS is not enabled, the PHSI field shall be omitted.

ROHC (refer to RFC 3095) may be used instead of PHS to compress IP headers. The MS and the BS signal enabling of ROHC by setting bit 7 of Request/Transmission Policy (see 11.13.12) to 0. When ROHC is enabled for a service flow, the service flow constitutes what in RFC 3095 is referred to as a ROHC channel.
Two service flows cannot share a ROHC channel, and two ROHC channels cannot share the same service flow. All IP packets that are classified onto a service flow for which ROHC has been enabled shall pass through the ROHC compressor on the sender side, and the decompressor on the receiver side.

ROHC compression and decompression operation shall be performed in accordance with RFC 3095, RFC 3759, RFC 3243, RFC 4995, RFC 3843, RFC 4996. To enable ROHC, the following two steps are required:

1) Capability negotiation during REG-REQ/RSP message exchange to determine whether ROHC is supported.
2) Indication in DSA-REQ/RSP messages to enable ROHC for the service flow.

**5.2.5.2 IP classification rules**

IP classification rules operate on the fields of the IP header and the transport protocol. The parameters (11.13.18.3.3.2 through 11.13.18.3.3.7 and 11.13.18.3.3.16) may be used in IP classification rules.
5.3 Generic Packet Convergence Sublayer (GPCS)

The Generic Packet CS (GPCS) is an upper layer protocol-independent packet convergence sublayer that supports multiple protocols over an IEEE 802.16 air interface. It is defined as follows:

— GPCS provides a generic packet convergence layer. This layer uses the MAC SAP and exposes a SAP to GPCS applications.

— GPCS does not re-define or replace other convergence sublayers. Instead, it provides a SAP that is not protocol specific.

— With GPCS, packet parsing happens “above” GPCS. The results of packet parsing are classification parameters given to the GPCS SAP for “parameterized classification,” but upper layer packet parsing is left to the GPCS application.

— With GPCS, the upper layer protocol that is immediately above the IEEE 802.16 GPCS is identified by a TLV parameter, GPCS protocol type, as defined in 11.13.19.5.1. The GPCS protocol type shall be included in C-SFM primitives and DSx messages during connection establishment.

— GPCS defines a set of SAP parameters as the result of upper layer packet parsing. These are passed from upper layer to the GPCS in addition to the data packet. The SAP parameters include SFID, MS MAC Address, data, and length. Each is defined in 5.3.3.

— GPCS allows multiplexing of multiple layer protocol types (e.g., IPv4, IPv6, Ethernet) over the same IEEE 802.16 connection. An appropriate upper protocol layer that supports protocol multiplexing is used to do this, and it is signaled in the GPCS_PROTOCOL_TYPE TLV in DSx messages to indicate that multiple protocols are supported for a connection/service flow. It is outside the scope of the GPCS to specify how the upper layer multiplexes and demultiplexes multiple protocol data packets over an IEEE 802.16 connection/service flow.

— For interoperability, upper layer protocol type may need an interface specification. Such a standard specification is out of scope of this document.

— With GPCS, the IEEE 802.1D bridging will be supported transparently by the IEEE 802.16 air interface, because the GPCS requires the upper layer to provide the MS MAC Address and SFID with every packet, where the MS MAC Address and SFID can represent a port and a port is either a unicast port or broadcast port.

— PHS as defined in 5.2.3 defines rules for how packets with suppressed fields are reconstructed based on the PHSI and the associated PHS rule. This reconstruction method can also be applied on packets transferred over the GPCS. Details are given in 5.3.6.
5.3.1 Mapping of the GPCS service to upper layers

In the case where a GPCS instance services only a single GPCS peer on an SS, the MS MAC Address field of the GPCS_DATA primitive shall be constant and set to the MAC address of the SS. The SFID field of the GPCS_DATA primitive shall be set to the SFID of the service flow being carried.

In the case where a GPCS instance services more than one SS, the MS MAC Address field of the GPCS_DATA primitive will indicate the SS that is the source or destination for the PDU. The SFID field of the GPCS_DATA primitive shall be set to the SFID of the service flow being carried.

5.3.2 Operation of GPCS with SSs that do not support the GPCS

A BS that supports GPCS may interoperate with an SS that does not support GPCS. It can be observed that a GPCS service with GPCS_PROTOCOL_TYPE 0x0000 (Ethernet MAC Service) carries packets formatted identically to the packets used in the IEEE 802.3 specific part of the Packet CS. Also, a GPCS service with GPCS_PROTOCOL_TYPE 0x0003 (Raw IP) carries packets formatted identically to the packets used in the IP specific part of the Packet CS.

A BS may operate using GPCS at the base station, locally using GPCS_PROTOCOL_TYPE=0x0000, while signaling to the SS during connection setup that the IEEE 802.3 specific part of the packet CS is being used.

A BS may operate using GPCS at the base station, locally using GPCS_PROTOCOL_TYPE=0x0003, while signaling to the SS during connection setup that the IP specific part of the packet CS is being used.
5.3.3 GPCS SAP parameters

The GPCS uses the GPCS SAP, an instance of the logical CS SAP. The GPCS SAP parameters enable the upper layer protocols to generically pass information to the GPCS so that the GPCS does not need to interpret upper layer protocol headers in order to map the upper layer data packets into proper IEEE 802.16 MAC connections. Since the SAP parameters are explicit, the parsing portion of the classification process is the responsibility of the upper layer. The parameters are relevant for SAP data path primitives, GPCS_DATA.request and GPCS_DATA.indication as described in 5.3.4 and 5.3.5, respectively.

**Service flow ID (SFID)**
Unique identifier to identify a unidirectional service flow for an MS. A GPCS implementation shall map the combination of SFID and MS MAC Address directly to a MAC connection ID. During connection / service flow establishment, the 802.16 control plane function shall provide GPCS the mapping information.

**MS MAC Address:**
48-bit unique identifier used by MS.

**DATA:**
The payload delivered by the GPCS upper layer to the GPCS, or by the GPCS to the upper layer.

**LENGTH:**
Number of bytes in DATA.

5.3.4 GPCS_DATA.request

5.3.4.1 Function
This primitive defines the transfer of data from the upper layer to the GPCS.

5.3.4.2 Semantics of the service primitive
The parameters of the primitive are as follows:

```c
GPCS_DATA.request
(
    SFID,
    MS MAC Address,
    length,
    data
)
```

The parameters SFID, MS MAC Address, length, and data are described in 5.3.3.

5.3.4.3 When generated
This primitive is generated by an upper layer protocol when a GPCS SDU is to be transferred to a peer entity or entities.

5.3.4.4 Effect of receipt
The receipt of this primitive causes GPCS to map the SFID and MS MAC Address to a unidirectional service flow, and thereby a connection. GPCS invokes MAC functions, for example the MAC SAP (an example MAC SAP definition is provided in Annex C) to effect transfer of the SDU to the MAC layer.
5.3.5 **GPCS_DATA.indication**

5.3.5.1 **Function**

This primitive defines the transfer of data from the GPCS to an upper layer protocol.

5.3.5.2 **Semantics of the service primitive**

The parameters of the primitive are as follows:

```
GPCS_DATA.indication
(
  SFID,
  MS MAC Address,
  length,
  data
)
```

The parameters SFID, MS MAC Address, length, and data are described in 5.3.3.

Note that SFID and MS MAC Address are not transferred over the IEEE 802.16 air interface. The GPCS shall map the CID to SFID and MS MAC Address, and then pass them to the upper layer of the GPCS through GPCS_DATA.indication, where the CID is provided in MAC SAP.

5.3.5.3 **When generated**

This primitive is generated by GPCS whenever a GPCS SDU is to be delivered to an upper layer protocol resulting from receipt of a MAC PDU.

5.3.5.4 **Effect of receipt**

The effect of receipt of this primitive by the upper layer protocol entity is dependent on the validity and content of the SDU.

5.3.6 **PHS operation**

PHS header suppression and reconstruction according to 5.2.3 may be deployed on particular GPCS service flows by installing PHS rules at the receiving side of the service flow using the procedures described in 5.2.3.2.
6. MAC common part sublayer

6.1 Point-to-multipoint (PMP) operation overview

The DL, from the BS to the user, operates on a PMP basis. The IEEE 802.16 wireless link operates with a central BS and a sectorized antenna that is capable of handling multiple independent sectors simultaneously. Within a given frequency channel and antenna sector, all stations receive the same transmission, or parts thereof. The BS is the only transmitter operating in this direction, so it transmits without having to coordinate with other stations, except for the overall time division duplexing (TDD) that may divide time into UL and DL transmission periods. The DL is generally broadcast. In cases where the DL-MAP does not explicitly indicate that a portion of the DL subframe is for a specific SS, all SSs capable of listening to that portion of the DL subframe shall listen. The SSs check the CIDs in the received PDUs and retain only those PDUs addressed to them.

SSs share the UL to the BS on a demand basis. Depending on the class of service utilized, the SS may be issued continuing rights to transmit, or the right to transmit may be granted by the BS after receipt of a request from the user.

In addition to individually addressed messages, messages may also be sent on multicast connections (control messages and video distribution are examples of multicast applications) as well as broadcast to all stations.

Within each sector, users adhere to a transmission protocol that controls contention between users and enables the service to be tailored to the delay and bandwidth requirements of each user application. This is accomplished through four different types of UL scheduling mechanisms. These are implemented using unsolicited bandwidth grants, polling, and contention procedures. Mechanisms are defined in the protocol to allow vendors to optimize system performance by using different combinations of these bandwidth allocation techniques while maintaining consistent interoperability definitions. For example, contention may be used to avoid individual polling of SSs that have been inactive for a long period of time.

The use of polling simplifies the access operation and guarantees that applications receive service on a deterministic basis if it is required. In general, data applications are delay tolerant, but real-time applications like voice and video require service on a more uniform basis and sometimes on a very tightly-controlled schedule.

The MAC is connection-oriented. For the purposes of mapping to services on SSs and associating varying levels of QoS, all data communications are in the context of a transport connection. Service flows may be provisioned when an SS is installed in the system. Shortly after SS registration, transport connections are associated with these service flows (one connection per service flow) to provide a reference against which to request bandwidth. Additionally, new transport connections may be established when a customer’s service needs change. A transport connection defines both the mapping between peer convergence processes that utilize the MAC and a service flow. The service flow defines the QoS parameters for the PDUs that are exchanged on the connection.

The concept of a service flow on a transport connection is central to the operation of the MAC protocol. Service flows provide a mechanism for UL and DL QoS management. In particular, they are integral to the bandwidth allocation process. An SS requests UL bandwidth on a per-connection basis (implicitly identifying the service flow). Bandwidth is granted by the BS to an SS as an aggregate of grants in response to per-connection requests from the SS.

Transport connections, once established, may require active maintenance. The maintenance requirements vary depending upon the type of service connected. For example, unchannelized T1 services require virtually no connection maintenance since they have a constant bandwidth allocated periodically. Channelized T1 services require some maintenance due to the dynamic (but relatively slowly changing)
bandwidth requirements if compressed, coupled with the requirement that full bandwidth be available on demand. IP services may require a substantial amount of ongoing maintenance due to their bursty nature and due to the high possibility of fragmentation. As with connection establishment, modifiable connections may require maintenance due to stimulus from either the SS or the network side of the connection.

Finally, transport connections may be terminated. This generally occurs only when a customer’s service requirements change. The termination of a transport connection is stimulated by the BS or SS.

All three of these transport connection management functions are supported through the use of static configuration and dynamic addition, modification, and deletion of service flows.

6.2 Reserved

6.3 Data/Control plane

6.3.1 Addressing and connections

6.3.1.1 Point-to-multipoint (PMP)

Each air interface in an SS shall have a 48-bit universal MAC address, as defined in IEEE Std 802®. This address uniquely defines the air interface of the SS. It is used during the initial ranging process to establish the appropriate connections for an SS. It is also used as part of the authentication process by which the BS and SS each verify the identity of the other.

Connections are identified by a 16-bit CID. At SS initialization, two pairs of management connections, basic connections (UL and DL) and primary management connections (UL and DL), shall be established between the SS and the BS, and a third pair of management connections (secondary management, DL and UL) may be optionally generated. The three pairs of management connections reflect the fact that there are inherently three different levels of QoS for management traffic between an SS and the BS. The basic connection is used by the BS MAC and SS MAC to exchange short, time-urgent MAC management messages. The primary management connection is used by the BS MAC and SS MAC to exchange longer, more delay-tolerant MAC management messages. Table 38 specifies which MAC management messages are transferred on which of these two connections. In addition, it also specifies which MAC management messages are transported on the broadcast connection. Finally, the secondary management connection is used by the BS and SS to transfer delay-tolerant, standards-based [Dynamic Host Configuration Protocol (DHCP), Trivial File Transfer Protocol (TFTP), SNMP, etc.] messages. Messages carried on the secondary management connection may be packed and/or fragmented. For the OFDM, and OFDMA PHYs, management messages shall have CRC. Use of the secondary management connection is required only for managed SS.

The CIDs for these connections shall be assigned in the RNG-RSP, REG-RSP or MOB_BSHO-REQ/RSP for pre-allocation in handover. When CID pre-allocation is used during HO, a primary management CID may be derived based on Basic CID without assignment in the messages (see 6.3.21.2.11). The message dialogs provide three CID values. The same CID value is assigned to both members (UL and DL) of each connection pair.

For bearer services, the BS and the SS may initiate the set-up of service flows based upon the provisioning information. The registration of an SS, or the modification of the services contracted at an SS, stimulates the higher layers of the BS and/or the SS to initiate the setup of the service flows. When admitted or active, service flows are uniquely associated with transport connections. MAC management messages shall never be transferred over transport connections. Bearer or data services shall never be transferred on the basic, primary, or secondary management connections.
Bearer connection CID reassignments during handover or network re-entry shall be sent using the REG-RSP encodings TLV in the RNG-RSP message, the REG-RSP message, or reassigned autonomously without explicit assignment in any message (see 6.3.21.2.11).

Requests for transmission are based on these CIDs, since the allowable bandwidth may differ for different connections, even within the same service type. For example, an SS unit serving multiple tenants in an office building would make requests on behalf of all of them, though the contractual service limits and other connection parameters may be different for each of them.

Many higher layer sessions may operate over the same wireless CID. For example, many users within a company may be communicating with Transmission Control Protocol (TCP)/IP to different destinations, but since they all operate within the same overall service parameters, all of their traffic is pooled for request/grant purposes. Since the original local area network (LAN) source and destination addresses are encapsulated in the payload portion of the transmission, there is no problem in identifying different user sessions.

The type of service and other current parameters of a service are implicit in the CID; they may be accessed by a lookup indexed by the CID.

6.3.2 MAC PDU formats

MAC PDUs shall be of the form illustrated in Figure 20. Each PDU shall begin with a fixed-length MAC header. The header may be followed by the Payload of the MAC PDU. If present, the Payload shall consist of zero or more subheaders and zero or more MAC SDUs and/or fragments thereof. The payload information may vary in length, so that a MAC PDU may represent a variable number of bytes. This allows the MAC to tunnel various higher layer traffic types without knowledge of the formats or bit patterns of those messages.

| MSB | MAC header | Payload (optional) | CRC (optional) | LSB |

Figure 20—MAC PDU formats

A MAC PDU may contain a CRC, as described in 6.3.3.5. Implementation of CRC capability is mandatory for OFDM and OFDMA PHYs. All reserved fields shall be set to zero on transmission and ignored on reception.
6.3.2.1 MAC header formats

The MAC header formats are defined in Table 3.

</tbody>
</table>

There is one defined DL MAC header, which is the Generic MAC header, which begins each DL MAC PDU containing either MAC management messages or CS data. There are two defined UL MAC header formats. The first is the generic MAC header that begins each MAC PDU containing either MAC management messages or CS data, where the header type (HT) is set to 0 as shown in Table 4. The second is the MAC header format without payload where HT is set to 1 as shown in Table 4. For the latter format, the header is not followed by any MAC PDU payload and CRC.

<td>Figure 30–Figure 32</td>
<td>Table 15, Table 16</td>
</tr>
</tbody>
</table>

<sup>a</sup>Headers with HT = 1 shall not be encrypted. Thus the EC field is used to distinguish between feedback MAC header (UL)/Compress MAP (DL), and all other type headers.

<sup>b</sup>Compressed DL-MAP and Reduced Private MAP do not use MAC headers as defined in 6.3.2.1; however, the first two bits of these maps replace the HT/EC fields and are always set to 0b11 to identify them as such (see 8.3.6.3, 8.3.6.7, 8.4.5.6, and 8.4.5.8). If the most significant bit of the Type field is set to 0, it indicates the presence of a compressed/reduced private DL-MAP. If the most significant bit of the Type field is set to 1, it indicates the presence of a SUB-DL-UL-MAP.
### 6.3.2.1.1 Generic MAC header

The generic MAC header is illustrated in Figure 21.

![Figure 21—Generic MAC header format](image)

The fields of the generic MAC header are defined in Table 5. Every header is encoded, starting with the HT and encryption control (EC) fields. The coding of these fields is such that the first byte of a MAC header shall never have the value of 0xFX, where “X” means “do not care.” This prevents false detection on the stuff byte used in the transmission convergence sublayer (TCS).

#### Table 5—Generic MAC header fields

<table>
<thead>
<tr>
<th>Name</th>
<th>Length (bit)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI</td>
<td>1</td>
<td>CRC indicator. 1 = CRC is included in the PDU by appending it to the PDU payload after encryption, if any. 0 = No CRC is included.</td>
</tr>
<tr>
<td>CID</td>
<td>16</td>
<td>Connection identifier.</td>
</tr>
<tr>
<td>EC</td>
<td>1</td>
<td>Encryption control. 0 = Payload is not encrypted or payload is not included. 1 = Payload is encrypted.</td>
</tr>
<tr>
<td>EKS</td>
<td>2</td>
<td>Encryption key sequence. The index of the traffic encryption key (TEK) and initialization vector (IV) used to encrypt the payload. This field is only meaningful if the EC field is set to 1.</td>
</tr>
<tr>
<td>ESF</td>
<td>1</td>
<td>Extended Subheader field. If ESF = 0, the extended subheader is absent. If ESF = 1, the extended subheader is present and shall follow the generic MAC header immediately. (See 6.3.2.2.7.) The ESF is applicable both in the DL and in the UL.</td>
</tr>
<tr>
<td>HCS</td>
<td>8</td>
<td>Header check sequence. An 8-bit field used to detect errors in the header. The transmitter shall calculate the HCS value for the first five bytes of the cell header, and insert the result into the HCS field (the last byte of the MAC header). It shall be the remainder of the division (Modulo 2) by the generator polynomial gD = D⁸ + D⁵ + D + 1 of the polynomial D⁸ multiplied by the content of the header excluding the HCS field. (Example: [HT EC Type] = 0x80, BR = 0xAAAA, CID = 0x0F0F; HCS would then be set to 0xD5).</td>
</tr>
</tbody>
</table>
The ESF bit in the Generic MAC header indicates that the extended subheader is present. Using this field, a number of additional subheaders can be used within a PDU. The extended subheader shall always appear immediately after the Generic MAC header and before all other subheaders. Contrary to the other subheaders, extended subheaders are not considered part of the MAC PDU payload and, hence are not encrypted. When an entity transmits a MAC PDU without a payload, it shall set the EC bit in the Generic MAC header to 0, even if the connection on which it transmits the MAC PDU is associated with data encryption. When an entity receives a MAC PDU that does not contain a payload, it shall process this MAC PDU if the EC bit is set to 0, and should discard this MAC PDU if the EC bit is set to 1.

The definition of the Type field is indicated in Table 6.

### Table 6—Type encodings

<table>
<thead>
<tr>
<th>Type bit</th>

</table>
| #4 | ARQ feedback payload  
| | 1 = present, 0 = absent |
| #3 | Extended type  
| | Indicates whether the present packing subheader (PSH) or fragmentation subheader (FSH) is extended for non-ARQ-enabled connections  
| | 1 = Extended  
| | 0 = Not extended  
| | For ARQ-enabled connections, this bit shall be set to 1. |
| #2 | Fragmentation subheader (FSH)  
| | 1 = present, 0 = absent |
| #1 | Packing subheader (PSH)  
| | 1 = present, 0 = absent |
| #0 least significant bit (LSB) | DL: Fast-feedback allocation subheader (FFSH)  
| | UL: Grant management subheader (GMSH)  
| | 1 = present, 0 = absent |

### 6.3.2.1.2 MAC header without payload

This MAC header format is applicable to UL only. The MAC header is not followed by any MAC PDU payload and CRC.
6.3.2.1.2.1 MAC signaling header type I

For this MAC header format, there is no payload following the MAC header. The MAC signaling header type I is illustrated in Figure 22. Table 7 describes the encoding of the 3-bit Type field following the EC field.

![Figure 22—MAC signaling header type I format](image)

6.3.2.1.2.1.1 Bandwidth request (BR) header

The BR PDU shall consist of BR header alone and shall not contain a payload. The BR header is illustrated in Figure 23. An MS receiving a BR header on the DL shall discard the PDU.

The BR header shall have the following properties:

a) It is a MAC signaling header type I.
b) The CID shall indicate the connection for which UL bandwidth is requested.
c) The BR field shall indicate the number of bytes requested.
d) The allowed types of BRs are defined in Table 7.

An SS receiving a BR header on the DL shall discard the PDU.

The fields of the BR header are defined in Table 8.

The BR header format is shown in Figure 23.

![BR header format](image)

6.3.2.1.2.1.2 Bandwidth request and UL Tx power report header

The BR and UL Tx power report PDU shall consist of BR and UL Tx power report header alone and shall not contain a payload. The BR and UL Tx power report header is illustrated in Figure 24.

![Figure 24—BR and UL Tx power report header format](image)

The BR and UL Tx power report header shall have the following properties:

a) This is a MAC signaling header type I.

b) The CID shall indicate the connection for which UL bandwidth is requested.

c) The allowed type for BR and UL Tx power report is defined in Table 7. The requested bandwidth is incremental.

The fields of the BR and UL Tx power report header are defined in Table 9.

<table>
<thead>

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).
6.3.2.1.2.1.3 BR and CINR report header

BR and CINR report PDU shall consist of BR and CINR report header alone, and shall not contain a payload (see Figure 25).

The BR and CINR report header shall have the following properties:

a) This is a MAC signaling header type 1.

b) The CID shall indicate the connection for which UL bandwidth is requested.

c) The allowed type for BR and CINR report header is defined in Table 7. The requested bandwidth is incremental.

The fields of the BR and CINR report header are defined in Table 10.

**Table 10—Description of the fields of BR and CINR report header**

</tbody>
</table>
CINR
This parameter indicates the CINR measured by the MS from the BS. It shall be interpreted as a single value from \(-16.0\) dB to \(47.5\) dB in units of \(0.5\) dB.

DCD Change Indication
This parameter is set to 1 if the DCD change count stored at the MS is not equal to that in the received DL-MAP message. Otherwise, it is set to 0.

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).

6.3.2.1.2.1 CQICH allocation request header

The CQICH allocation request PDU shall consist of a CQICH allocation request header alone and shall not contain a payload. This header is sent by the MS to request the allocation of a CQICH. The CQICH allocation request header is illustrated in Figure 26.

![Figure 26—CQICH allocation request](image)

The CQICH allocation request header shall have the following properties:

a) This is a MAC signaling header type I.
b) The CID shall indicate the MS Basic CID.
c) The allowed type for CQICH allocation request is defined in Table 7.
The fields of the CQICH allocation request header are defined in Table 11.

### Table 11—Description of the fields of CQICH allocation request header

</table>

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).

**6.3.2.1.2.1.5 PHY channel report header**

The PHY channel report PDU shall consist of a PHY channel report header alone and shall not contain a payload. The PHY channel report header is illustrated in Figure 27.

![Figure 27—PHY channel report header](image)

The PHY channel report shall have the following properties:

a) This is a MAC signaling header type I.
b) The CID shall indicate the MS Basic CID.
c) The allowed type for PHY channel report is defined in Table 7.
An MS receiving a PHY channel report header on the DL shall discard the PDU.

The fields of the PHY channel report header are defined in Table 12.

</table>

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).

**6.3.2.1.2.1.6 BR and UL sleep control header**

The BR and UL sleep control header is sent by the MS to request activation/deactivation of certain power saving class. The header also indicates incremental transmission demand. The BR and UL sleep control PDU shall consist of a BR and UL sleep control header alone and shall not contain a payload. The BR and UL sleep control header is illustrated in Figure 28.
The BR and UL sleep control header shall have the following properties:

a) This is a MAC signaling header type I.
b) The CID shall indicate the connection for which the uplink bandwidth is requested.
c) The allowed type for BR and UL sleep control is defined in Table 7.

An MS receiving a BR and UL sleep control header on the DL shall discard the PDU.

The fields of the BR and UL sleep control header are defined in Table 13.

**Table 13—BR and UL sleep control header fields**

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).
6.3.2.1.2.1.7 SN report header

The SN report header is sent by the MS to report the LSB of the next ARQ BSN or the virtual MAC SDU Sequence number for the active connections with SN Feedback enabled. The SN report header is illustrated in Figure 29.

![Figure 29—SN report header format](image)

The SN report header shall be of the form illustrated in Figure 29. The SN report header shall have the following properties:

a) This is a MAC signaling header type I.
b) The CID shall indicate the basic connection of the MS for which the SN Report is being sent.
c) The allowed type for SN report header is defined in Table 7.
d) The SDU SN field shall indicate the next ARQ BSN or the virtual MAC SDU Sequence number for the active connections with SN Feedback enabled. In the latter case, the 8-bit virtual MAC SDU Sequence number shall be mapped into the LSBs of the SDU SN and the three MSBs of the SDU SN shall be set to zero.

An MS receiving a SN report header on the DL shall discard the PDU.

The fields of the SN report header are defined in Table 14.

<table>

Support of this subheader shall be negotiated between the BS and MS as part of the registration dialog (REG-REQ/RSP).
6.3.2.1.2.2 MAC signaling header type II

This type of MAC header is UL-specific. There is no payload following the MAC header. The MAC signaling header type II is illustrated in Figure 30. Table 15 describes the encoding of the 1-bit type field following the EC field. The description of DL MAC header format with HT/EC = 0b11, defined as the Compressed DL-MAP, is not part of this subclause. The detailed description can be found in 8.4.5.6.1.

![Figure 30—MAC signaling header type II format](image)

6.3.2.1.2.2.1 Feedback header

The feedback header is sent by an MS either as a response to a Feedback Polling IE (see 8.4.5.4.26) or as an unsolicited feedback. When sent as a response to a Feedback Polling IE, the MS shall send a feedback header using the assigned resource indicated in the Feedback Polling IE. When sent as unsolicited feedback, the MS can either send the feedback header on currently allocated UL resource or request additional UL resource by sending an Indication flag on the fast-feedback channel or the enhanced fast-feedback channel (refer to 8.4.11.11) or by sending a BR ranging code.

The feedback PDU shall consist of the feedback header alone and shall not contain a payload. The feedback header with and without the CID field are illustrated in Figure 31 and Figure 32. The feedback header with the CID field shall be used when the UL resource used to send the feedback header is requested through BR ranging. Otherwise, the feedback header without the CID field shall be used.
The fields of feedback header are defined in Table 16.

**Table 16—Description of the fields of feedback header**

<table>
<thead>
<tr>
<th>Name</th>
<th>Length (bit)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CII</td>
<td>1</td>

</tr>
<tr>
<td>Feedback Type</td>
<td>4</td>
<td>Set according to Table 17.</td>
</tr>
</tbody>
</table>
The feedback header shall have the following properties:

a) This is a MAC signaling header type II. The length of the header shall always be 6 bytes.
b) The allowed type for feedback header is defined in Table 15.
c) The Feedback Type field shall be set according to Table 17.
d) The CII field (CID Inclusion Indication) shall be set to 1 for the header with CID field and set to 0 for the header without CID field.
e) The Feedback Content field shall be set accordingly based on the value of the feedback type field.
f) When the size of the defined content, as given in Table 17, for any Feedback type is less than the size of the Feedback Contents field, the defined content shall be bit-aligned to the LSB of the Feedback Contents field and all unused bits of the Feedback Contents field shall be set to a value of '0'.

The feedback header may be used by the MS to provide its feedback(s). An MS receiving a feedback header on the DL shall discard the PDU.

The support of feedback header is OFDMA-PHY-specific and shall be negotiated between the BS and the MS as part of the registration dialog (REG-REQ/RSP).

6.3.2.1.2.2.1 MIMO channel feedback header

The MIMO channel feedback header is used for MS to provide DL MIMO channel quality feedback to the BS. The MIMO channel feedback header can be used to provide a single or composite channel feedback. The MIMO channel feedback header with or without Basic CID field is illustrated in Figure 33 and Figure 34, respectively.

### Table 17—Feedback type and feedback content (continued)

<table>
<thead>
<tr>
<th>Feedback type (binary)</th>
<th>Feedback contents</th>
<th>Description</th>
</tr>

|        |              | 0b1101: 1/32 
|        |              | 0b1110: 1/48 
|        |              | 0b1111: 1/64 
|        |              | where Ratio = BW_{preferred}/BW_{used}. |
|        |              | BW_{preferred}: Preferred bandwidth for DIUC transmission, |
|        |              | BW_{used}: Actual used channel bandwidth (excluding guard bands). |
| SLPB   | 7            | Starting location of preferred bandwidth: 0–127. This field points to the starting preferred bandwidth location. This field, combined with the PBWI field, tells the BS the exact size and location of the preferred bandwidth in the channel. The effective bandwidth (used bandwidth) is divided into 128 intervals numbered 0 to 127 counting from the lower to the higher band. SLPB indicates the starting location of preferred bandwidth for the DIUC burst profile. |
| BPRI   | 1/2          | Burst profile ranking indicator. This field can be used to rank up to four preferred burst profiles within the DL channel. BPRI (without Basic CID) indicates the ranking for DL channel condition of the preferred bandwidth as reported in the current header where 0 is the most preferred bandwidth: |
|        |              | 0b00: 1\(^{st}\) preferred burst profile |
|        |              | 0b10: 2\(^{nd}\) preferred burst profile |
|        |              | 0b01: 3\(^{rd}\) preferred burst profile |
|        |              | 0b11: 4\(^{th}\) preferred burst profile |
|        |              | BPRI (including Basic CID): |
|        |              | 0b0: 1\(^{st}\) preferred burst profile |
|        |              | 0b1: 2\(^{nd}\) preferred burst profile |
|        |              | This field is 1 bit when CII is set to 1; otherwise, this field is 2 bits. |
| CTI    | 3            | Coherent time index. This field provides coherent time information. CTI indicates the estimated duration of the valid MIMO channel conditions: |
|        |              | 0b000: Infinite |
|        |              | 0b001: 1 frame |
|        |              | 0b010: 2 frames |
|        |              | 0b011: 3 frames |
|        |              | 0b100: 4 frames |
|        |              | 0b101: 8 frames |
|        |              | 0b110: 14 frames |
|        |              | 0b111: 24 frames |
|        |              | This field is present only when CII is set to 0. |
5.3.2.2 MAC subheaders and special payloads

Five types of subheaders may be present in a MAC PDU with generic MAC header; four per-PDU subheader types and one per-SDU subheader type. The per-PDU subheaders (i.e., extended subheaders, FSH, FFSH, and GMSH) may be inserted in the MAC PDUs immediately following the generic MAC header. If both the FSH and GMSH are indicated, the GMSH shall come first. In the DL, the FFSH shall always appear as the last per-PDU subheader. The ESF bit in the generic MAC header indicates that one or more extended subheaders are present in the PDU. The extended subheaders shall always appear immediately after the generic MAC header and before all other subheaders. All extended subheaders are not encrypted. (See 6.3.2.2.7.)

The only per-SDU subheader is the PSH. It may be inserted before each MAC SDU if so indicated by the Type field. The PSH and FSH are mutually exclusive and shall not both be present within the same MAC PDU.

When present, per-PDU subheaders shall always precede the first per-SDU subheader.
6.3.2.2.1 Fragmentation subheader (FSH)

The FSH is shown in Table 19.

6.3.2.2.2 Grant management subheader (GMSH)

The GMSH is 2 bytes in length and is used by the SS to convey bandwidth management needs to the BS. This subheader is encoded differently based upon the type of UL scheduling service for the connection (as given by the CID). The use of this subheader is defined in 6.3.6. The GMSH is shown in Table 20. Its fields are defined in Table 21. The capability of GMSH at both BS and SS is optional.

| FLI | 1 | Frame latency indication  
| | | 0 = FL field disabled for this grant  
| | | 1 = FL field enabled for this grant |
| FL | 4 | Frame latency. The number of frames previous to the current one in which the transmitted data was available. When the latency is greater than 15 then the FL field shall be set to 15. |
| Extended Piggyback Request | 11 | The number of bytes of UL bandwidth requested by the MS. The BR is for the CID. The request shall not include any PHY overhead. In case of Extended rtPS, the BS changes its grant size to the size specified in this field. |
| PBR | 16 | Piggyback request. The number of bytes of UL bandwidth requested by the SS. The BR is for the CID. The request shall not include any PHY overhead. The request shall be incremental. |
| PM | 1 | Poll me  
| | | 0 = No action  
| | | 1 = Used by the SS to request a bandwidth poll. |
| Reserved | 9 | — |
| SI | 1 | Slip indicator  
| | | 0 = No action  
| | | 1 = Used by the SS to indicate a slip of UL grants relative to the UL queue depth. |
6.3.2.2.3 Packing subheader (PSH)

When packing (see 6.3.3.4) is used, the MAC may pack multiple SDUs into a single MAC PDU. When packing variable-length MAC SDUs, the MAC precedes each one with a PSH. The PSH is defined in Table 22.

</tbody>
</table>

6.3.2.2.4 ARQ feedback

If the ARQ Feedback Payload bit in the MAC Type field (see Table 6) is set, the ARQ Feedback Payload shall be transported. If packing is used, it shall be transported as the first packed payload. See 6.3.3.4.3. Note that this bit does not address the ARQ Feedback payload contained inside an ARQ Feedback message.
6.3.2.2.5 Reserved

6.3.2.2.6 Fast-feedback allocation subheader (FFSH)

The format of the FFSH is specified in Table 23. The FFSH, when used, shall always be the last per-PDU subheader as specified in 6.3.2.2. The support of the FFSH is PHY-specification-specific.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>

</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Allocation offset**

Defines the offset, in units of slots, from the beginning of the fast-feedback UL bandwidth allocation (8.4.5.4.9), of the slot in which the SS servicing the CID appearing in the generic MAC header shall send a fast-feedback message. Range of values is 0 to 63. The allocation applies to the UL subframe two frames after the frame including the FFSH.

6.3.2.2.7 Extended subheader format

The extended subheader group (see Figure 35), when used, shall always appear immediately after the generic MAC header and before all subheaders, and, if the MAC PDU contains an encrypted payload (i.e., the EC bit is set to 1), the packet number (PN), as described in 6.3.2.2. The extended subheader group format is specified in Table 24, Table 25, and Table 26. Extended subheaders shall not be encrypted.
The fields of the extended subheader group structure are described in Table 24.

Table 24—Extended subheader group format

<table>
<thead>
<tr>
<th>Name</th>
<th>Size (bit)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extended Subheader Group Length</td>
<td>8</td>

<tr>
<td>Extended Subheader Body</td>
<td>variable</td>
<td>The size of the extended subheader is determined by extended subheader type as specified in Table 25 and Table 26. The size of the extended subheader body is byte aligned.</td>
</tr>
</tbody>
</table>
The extended subheader group starts with an 8-bit Extended Subheader Group Length field that is followed by one or multiple extended subheaders. The length field specifies the total length in bytes of the subheader group, including all the extended subheaders and the length byte. Each extended subheader consists of a reserved bit, a 7-bit Extended Subheader Type field, and a variable-size extended subheader body. The size of each extended subheader is determined by the extended subheader type as specified in Table 25.

The list of defined extended subheaders is given in Table 25 for the DL and in Table 26 for the UL. The support of each extended subheader shall be negotiated between the BS and the MS as part of the registration dialog (REG-REQ/RSP).

</tbody>
</table>
6.3.2.2.7.1 SDU SN extended subheader

The SDU SN extended subheader shall only be sent by the BS if SDU SN extended subheader capability is supported (negotiated through REG-REQ/RSP) and if SDU_SN Feedback is enabled for a DL connection (negotiated through DSA-REQ/RSP). The SDU SN extended subheader shall contain the last virtual MAC SDU sequence number of current MAC PDU. The format of the SDU SN extended subheader is as described in Table 27.

Table 27—SDU SN extended subheader format

<tbody>
<tr>
<td>SDU sequence number</td>
<td>8</td>
<td>Last virtual MAC SDU sequence number in the current MAC PDU.</td>
</tr>
</tbody>
</table>

6.3.2.2.7.2 DL sleep control extended subheader

The DL sleep control extended subheader is sent by the BS to activate/deactivate certain power saving class. The requested operation is effective from the start frame carried in the DL sleep control extended subheader according to the format defined in Table 28. The format of DL sleep control extended subheader is as described in Table 28. The BS may transmit this message to reactivate the Power Saving Class after the BS determines the end of data transmission.

Table 28—DL sleep control extended subheader format

</tr>
</tbody>
</table>

6.3.2.2.7.3 Feedback request extended subheader

Feedback request extended subheader shall only be sent by the BS to provide a UL allocation for a fast-feedback channel transmission (see 8.4.11). The BS shall indicate in the fast-feedback request subheader transmission the applied frame for the UL allocation.
The format of the feedback request extended subheader is as described in Table 29.

### Table 29—Feedback request extended subheader format

<table>

<td>Indicate to report at the frame. If $F = 0$, the allocation applies to the UL subframe two frames ahead of the current frame. If $F = 1$, four frames ahead of the current frame.</td>
</tr>
</tbody>
</table>

### 6.3.2.2.7.4 MIMO mode feedback extended subheader

An MS uses the MIMO feedback extended subheader to provide its feedback in terms of MIMO mode feedback. When there is an UL MAC PDU payload to be transmitted at the same time. The format of the MIMO mode feedback extended subheader is as described in Table 30.

### Table 30—MIMO mode feedback extended subheader format

<table>
<thead>

</tr>
</tbody>
</table>

For each MS, if a MIMO mode feedback extended subheader is present, it shall only appear in the first unicast PDU transmitted by that MS in that frame.
6.3.2.2.7.5 UL Tx power report extended subheader

This subheader is sent from MS to BS to report the Tx power of the burst that carries this subheader. The format of the UL Tx power report extended subheader is as described in Table 31.

<table>
<thead>
<tr>

</table>

6.3.2.2.7.9 ertPS resumption bitmap extended subheader

An MS may have multiple ertPS service flows that have been stopped by the MS by sending BR headers with BR = 0. When the MS has more than one ertPS service flow to resume at the same time, the MS may include the following extended subheader in a MAC PDU to request the serving BS to resume scheduling of the identified ertPS service flows. When the BS receives this extended subheader, the BS shall allocate a UL burst for each UL ertPS service flow identified by the extended subheader.

Table 36—ertPS resumption bitmap extended subheader

</tr>
</tbody>
</table>

6.3.2.2.7.10 Persistent Allocation Error Event

The Persistent Allocation Error Event is used by the MS to indicate failure with a persistent allocation. The fields of the Persistent Allocation Error Event extended subheader are defined in Table 37.
6.3.2.3 MAC management messages

A set of MAC management messages are defined. These messages shall be carried in the Payload of the MAC PDU. All MAC management messages begin with a Management Message Type field and may contain additional fields. MAC management messages on the basic, broadcast, and initial ranging connections shall be neither fragmented nor packed. MAC management messages on the primary management connection may be packed and/or fragmented. MAC management messages on the fragmentable broadcast connection may be fragmented. For the OFDM, and OFDMA PHY's, management messages carried on the initial ranging, broadcast, fragmentable broadcast, basic, and primary management connections shall have CRC usage enabled. The format of the management message is given in Figure 36. The encoding of the Management Message Type field is given in Table 38. MAC management messages shall not be carried on transport connections. MAC management messages that have a Type value specified in Table 38 as reserved, or those not containing all required parameters or containing erroneously encoded parameters, shall be silently discarded. In case of MAC management messages with multiple presentations of the same TLV and/or encoded parameter information, the last presentation shall be used, unless otherwise specified that multiple presentations are allowed (e.g., Downlink_Burst_Profile TLV in DCD message), in which case all presentations shall be used.

</tbody>
</table>

*For SSs and BSs that support PKMv2, PKM-RSP is sometimes transmitted on the broadcast connection.*
In general, the PKM-RSP messages are carried on the Primary Management connection. However, the PKMv2 Group-Key-Update-Command message for the GTEK update mode shall be carried on the Broadcast connection.

During the adaptive antenna system (AAS) portion of the frame, the DL-MAP, UL-MAP, DCD, UCD, MOB_NBR-ADV, MOB_TRF-IND, MOB_PAG-ADV, and CLK-CMP messages may be sent using the Basic CID.

6.3.2.3.1 DCD (DL channel descriptor) message

A DCD shall be transmitted by the BS at a periodic interval (Table 554) to define the characteristics of a DL physical channel.

### Table 39—DCD message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCD_Message_Format()</td>
<td>—</td>

<td>—</td>
<td>For each DL burst profile 1 to n</td>
</tr>
<tr>
<td>Downlink_Burst_Profile</td>
<td>—</td>
<td>PHY-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

A BS shall generate DCDs in the format shown in Table 39, including all of the following parameters:

**Configuration Change Count**

Incremented by one (modulo 256) by the BS whenever any of the values of this channel descriptor change, except for the frame number for the OFDM PHY and the Available DL Radio Resources. If the value of this count in a subsequent DCD remains the same, the SS can quickly decide that the remaining fields have not changed and may be able to disregard the remainder of the message. An SS performing initial network entry should decode the Available DL Radio Resources even if the DCD Configuration Change Count remains unchanged.

The following WirelessMAN-OFDM PHY-specific parameter shall be included in the DCD message:

**Frame Duration Code**

**Frame Number**
The message parameters following the Configuration Change Count shall be encoded in a TLV form (see 11.4). All channel encodings (see 11.4.1) shall appear first before the Downlink_Burst_Profile encodings.

The Downlink_Burst_Profile is a compound TLV encoding that defines, and associates with a particular DL interval usage code (DIUC), the PHY characteristics that shall be used with that DIUC. Within each Downlink_Burst_Profile shall be an unordered list of PHY attributes, encoded as TLV values (see 11.4.2). Each interval is assigned a DIUC by the DL-MAP message. A Downlink_Burst_Profile shall be included for each DIUC to be used in the DL-MAP unless the PHY’s Downlink_Burst_Profile is explicitly known.

Downlink_Burst_Profile contents are defined separately for each PHY specification in Clause 8.

For OFDMA PHY, the DCD message (if such exists) shall always be transmitted on a DL burst described by a DL-MAP IE with DIUC=0 and DIUC = 0 shall have burst profile parameters that are the same as those used for transmission of the DL-MAP message.

6.3.2.3.2 DL-MAP (Downlink map) message

The DL-MAP message defines the access to the DL information. If the length of the DL-MAP message is a nonintegral number of bytes, the LEN field in the MAC header is rounded up to the next integral number of bytes. The message shall be padded to match this length, but the SS shall disregard the 4 pad bits.

<table>
<thead>
<tr>
<th>Table 40—DL-MAP message format</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Syntax</strong></td>
</tr>
<tr>
<td>DL-MAP_Message_Format() {</td>
</tr>
<tr>
<td>Management Message Type = 2</td>

<tr>
<td>}</td>
</tr>
<tr>
<td>for (i = 1; i &lt;= n; i++) {</td>
</tr>
<tr>
<td>DL-MAP_IE()</td>
</tr>
<tr>
<td>}</td>
</tr>
<tr>
<td>}</td>
</tr>
<tr>
<td>if !(byte boundary)</td>
</tr>
</tbody>
</table>
A BS shall generate DL-MAP messages in the format shown in Table 40, including all of the following parameters:

**PHY Synchronization**

The PHY synchronization field is dependent on the PHY specification used. The encoding of this field is given in each PHY specification separately.

**DCD Count**

Matches the value of the configuration change count of the DCD, which describes the DL burst profiles that apply to this map.

**Base Station ID**

The Base Station ID is a 48-bit long field identifying the BS. The least significant 24 bits of the Base Station ID shall be programmable. The most significant 24 bits shall be used as the Operator ID. This is a network management hook that can be sent with the DCD message for handling edge-of-sector and edge-of-cell situations. The 24-bit Operator ID shall be assigned as an IEEE 802.16 Operator ID by the IEEE Registration Authority. The IEEE Registration Authority shall be the sole authorized number space administrator for this function.

The encoding of the remaining portions of the DL-MAP message is PHY-specification dependent and may be absent. Refer to the appropriate PHY specification.

The UL-MAP message (when present) shall be always transmitted in the first PDU on the burst described by the first DL-MAP IE of the DL-MAP (or, in the case of the OFDM PHY mode, of the DLFP).

The DL-MAP IEs in the DL-MAP shall be ordered in the increasing order of the transmission start time of the relevant PHY burst. The transmission start time is conveyed by the contents of the DL_MAP IE in a manner that is PHY dependant.

The logical order in which MAC PDUs are mapped to the PHY bursts in the DL is defined as the order of DL-MAP IEs in the DL-MAP message.

### 6.3.2.3.3 UCD (UL channel descriptor) message

A UCD shall be transmitted by the BS at a periodic interval (Table 554) to define the characteristics of an UL physical channel.

A BS shall generate UCDs in the format shown in Table 41, including all of the following parameters:

---

13The IEEE Registration Authority is a committee of the IEEE Standards Association Board of Governors. General information as well as details on the allocation of IEEE 802.16 Operator ID can be obtained at http://standards.ieee.org/regauth.
Configuration Change Count
Incremented by one (modulo 256) by the BS whenever any of the values of this channel descriptor change, except for the Available UL Radio Resources. If the value of this count in a subsequent UCD remains the same, the SS can quickly decide that the remaining fields have not changed and may be able to disregard the remainder of the message. An SS performing initial network entry should decode the Available UL Radio Resources even if the UCD Configuration Change Count remains unchanged. This value is also referenced from the UL-MAP messages.

Ranging Backoff Start
Initial backoff window size for initial ranging contention, expressed as a power of 2. Values of $n$ range 0–15 (the highest order bits shall be unused and set to 0).

Ranging Backoff End
Final backoff window size for initial ranging contention, expressed as a power of 2. Values of $n$ range 0–15 (the highest order bits shall be unused and set to 0).

Request Backoff Start
Initial backoff window size for contention BRs, expressed as a power of 2. Values of $n$ range 0–15 (the highest order bits shall be unused and set to 0).

Request Backoff End
Final backoff window size for contention BRs, expressed as a power of 2. Values of $n$ range 0–15 (the highest order bits shall be unused and set to 0).

<td>—</td>
</tr>
</tbody>
</table>
To provide for flexibility, the remaining message parameters shall be encoded in a TLV form (see 11.3). All Channel encodings (see 11.3.1) shall appear first before the Uplink_Burst_Profile encodings.

The Uplink_Burst_Profile is a compound TLV encoding that defines, and associates with a particular UIUC, the PHY characteristics that shall be used with that UIUC. Within each Uplink_Burst_Profile shall be an unordered list of PHY attributes, encoded as TLV values (see 11.3.1.1 for an example applicable to the 10–66 GHz PHY specification). Each interval is assigned a UIUC by the UL-MAP message. An Uplink_Burst_Profile shall be included for each UIUC to be used in the UL-MAP.

Uplink_Burst_Profile contents are defined separately for each PHY specification in Clause 8.

6.3.2.3.4 UL-MAP (UL map) message

The UL-MAP message allocates access to the UL channel. The UL-MAP message shall be as shown in Table 42.

The BS shall generate the UL-MAP with the following parameters:

UCD Count
Matches the value of the Configuration Change Count of the UCD, which describes the UL burst profiles that apply to this map.

Allocation Start Time
Effective start time of the UL allocation defined by the UL-MAP (units are PHY-specific, see 10.3).

Map IEs
The contents of a UL-MAP IE is PHY-specification dependent.

IEs define UL bandwidth allocations. Each UL-MAP message (except when the PHY is an OFDMA PHY) shall contain at least one information element (IE) that marks the end of the last allocated burst. Ordering of IEs carried by the UL-MAP is PHY-specific.

The CID represents the assignment of the IE to either a unicast, multicast, or broadcast address. When specifically addressed to allocate a bandwidth grant, the CID shall be the Basic CID of the SS. A UIUC shall be used to define the type of UL access and the UL burst profile associated with that access. An Uplink_Burst_Profile shall be included in the UCD for each UIUC to be used in the UL-MAP.

For SC, and OFDMA PHYs, the UL-MAP message (if such exists) shall always be transmitted on the burst described by the first DL-MAP IE (and following the HARQ MAP Pointer IE, if such exists in the OFDMA PHY) of the DL-MAP message. If there are multiple PDUs in the burst described by the first DL-MAP IE, the UL-MAP message shall be the first one.

The logical order in which MAC PDUs are mapped to the PHY bursts in the UL is defined as the order of UL-MAP IEs in the UL-MAP message.

</table>
6.3.2.3.5 RNG-REQ (ranging request) message

An RNG-REQ shall be transmitted by the SS at initialization and periodically to determine network delay and to request power and/or DL burst profile change. The format of the RNG-REQ message is shown in Table 43. The RNG-REQ message may be sent in initial ranging and data grant intervals.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNG-REQ_Message_Format()</td>
<td>—</td>

<td>Shall be set to zero</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The CID field in the MAC header shall assume the following values when sent in an initial ranging interval:

a) Initial Ranging CID if the SS is attempting to join the network.
b) Initial Ranging CID if the SS has not yet registered and is changing DL (or both DL and UL) channels.
c) In all other cases, the Basic CID is used as soon as one is assigned in the RNG-RSP message.

If sent in a data grant interval, the CID is always equal to the Basic CID.

An SS shall generate RNG-REQ messages in the format shown in Table 43.

All parameters are coded as TLV tuples as defined in 11.5.

TLV message elements shall only be included in RNG-REQ messages of adequate UL bandwidth. In OFDMA, when the MS transmits the HO CDMA ranging code, the BS shall provide for initial UL bandwidth allocation of size at least sufficient for transmission of RNG-REQ message with MS MAC address TLV and GMSH. If required TLV message elements cannot be accommodated in the UL bandwidth of a current RNG-REQ message, after the MS obtains a Basic CID from the BS, the MS shall make UL BR of sufficient size to conduct additional RNG-REQ including all required message elements, at the first available opportunity.

The following parameters shall be included in the RNG-REQ message when the SS is attempting initial entry to the network:

- **Requested Downlink Burst Profile**
- **SS MAC Address**

The following parameters shall be included in the RNG-REQ message when transmitted during SS initial entry to the network. The parameter shall be sent on the SS’s basic connection or for OFDMA on the following initial ranging connection:

- **MAC Version (11.1.3)**
The following parameters may be included in the RNG-REQ message after the SS has received a RNG-RSP addressed to the SS:

**Requested Downlink Burst Profile**

**Ranging Anomalies**

The following parameter may be included in the RNG-REQ message:

**AAS broadcast capability**

The following parameter may be included in the RNG-REQ message when the MS is attempting to perform reentry, association, or HO:

**Requested Downlink Burst Profile**

The following parameter shall be included in the RNG-REQ message when the MS is attempting to perform reentry, association, or HO:

**Serving BSID**

The BSID of the BS to which the MS is currently connected (has completed the registration cycle and is in normal operation). The serving BSID shall not be included if the aging timer is timed-out (serving BSID AGINGTIMER; see Table 554). Inclusion of serving BSID in the RNG-REQ message signals to the target BS that the MS is currently connected to the network through the serving BS and is performing association or is in the process of HO network reentry.

The following TLV parameter shall be included in the RNG-REQ message when the MS is attempting to perform reentry, HO, or location update:

**Ranging Purpose Indication**

The presence of this item in the message indicates the following MS action:

If Bit 0 is set to 1, in combination with a serving BSID, it indicates that the MS is currently attempting to HO or reentry; or, in combination with a Paging Controller ID, indicates that the MS is attempting network reentry from idle mode to the BS.

If Bit 1 is set to 1, it indicates that the MS is initiating the idle mode location update process.

Bit 2: Seamless HO indication. When this bit is set to 1 in combination with other included information elements, it indicates the MS is initiating ranging as part of seamless HO procedure.

Bit 3: Ranging Request for Emergency Call Setup. When this bit is set to 1, it indicates MS action of Emergency Call Process.

Bit 4: MBS update. When this bit is set to 1, the MS is currently attempting to perform location update due to a need to update service flow management encodings for MBS flows.

Bits 5–7: Reserved

The following TLV parameter shall be included in the RNG-REQ message when the MS is attempting to perform reentry or location update:

**Paging Controller ID** (see 11.1.8.2)

The Paging Controller ID is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in idle mode.
The following TLV parameter shall be included in the RNG-REQ message when the MS in Idle Mode is attempting to change Paging Cycle during Location Update:

**Paging Cycle Change** (see 11.5)

PAGING_CYCLE requested by the MS

The following TLV parameter may be included in RNG-REQ message when an MS is performing initial ranging to the selected target BS:

**HO_ID**  
Optional ID assigned for use in initial ranging to the target BS during HO once the BS is selected as the target BS (see 6.3.21.2.7).

The following parameter may be included in the RNG-REQ message when the MS is attempting to perform reentry, association, or HO:

**MS MAC Address**  
MS MAC Address shall be included if HO_ID is omitted.

The following TLV parameter may be included in the RNG-REQ message when MS is attempting to perform location update:

**MAC Hash Skip Threshold** (see 11.1.8.1)  
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC address hash of an MS for which the action code is 00 (No Action Required).

The following TLV parameter shall be included in the RNG-REQ message when the MS is attempting to perform location update due to power down:

**Power Down Indicator**  
Indicates the MS is currently attempting to perform location update due to power down.

The following parameters may be included in RNG-REQ message when the MS is attempting to perform HO and needs to inform target BS of its preference to define Power Saving Class during HO to target BS.

**Power_Saving_Class_Parameters**  
Compound TLV to specify power saving class operation.

The following TLV shall be included whenever the CMAC tuple is included in the RNG-REQ message during re-entry, secure Location Update or handover.

**CMAC_KEY_COUNT**  
This field contains the MSs current value of the CMAC_KEY_COUNT, which is used to generate the CMAC_KEY_U used to generate the CMAC Tuple included in this message. See 7.2.2.2.9.

The following parameter shall be included in the RNG-REQ message when the MS is attempting to perform Network Re-Entry from idle mode, Keep-Alive check in sleep mode, Secure Location Update, or HO and the MS has a hashed message authentication code (HMAC)/cipher-based message authentication code (CMAC) tuple necessary to expedite security authentication.

**HMAC/CMAC Tuple (see 11.1.2)**  
The HMAC/CMAC Tuple shall be the last attribute in the message.
6.3.2.3.6 RNG-RSP (ranging response) message

A RNG-RSP shall be transmitted by the BS in response to a received RNG-REQ. In addition, it may also be transmitted asynchronously to send corrections based on measurements that have been made on other received data or MAC messages. As a result, the SS shall be prepared to receive a RNG-RSP at any time, not just following a RNG-REQ transmission. The format of the RNG-REQ message is shown in Table 44.

To provide for flexibility, the message parameters following the Uplink Channel ID shall be encoded in a TLV form.

All other parameters are coded as TLV tuples, as defined in 11.6.

</tr>
</tbody>
</table>
Frequency Adjust Information
AAS Broadcast Permission
Preamble Index Override

Preamble Indices of new target BS(s) where the MS should redo ranging. If the TLV includes two or more Preamble Indices, the first one in the list is the most preferable and the second is the next preferable. When the TLV is used with Downlink frequency override TLV, the MS should redo ranging on the new DL channel identified by the Preamble Indices.

Ranging Abort Timer
Timer defined by a BS to prohibit the MS from attempting network entry at this BS, for a specific time duration.

The following WirelessMAN-OFDM PHY-specific parameters may also be included in the RNG-RSP message:

Frame Number
Frame number in which the corresponding RNG-REQ message or subchannelized initial ranging indication (for OFDM) was received. When Frame Number is included, SS MAC Address shall not appear in the same message.

Initial Ranging Opportunity Number
Initial ranging opportunity within the frame in which the corresponding RNG-REQ message or subchannelized initial ranging indication (for OFDM) was received. If not provided, and Frame Number is included in the message, initial ranging opportunity is assumed to be one.

The following WirelessMAN-OFDM PHY-specific parameter may also be included in the RNG-RSP message:

Ranging Subchannel
The OFDM ranging subchannel index that was used to transmit the initial ranging message.

The following WirelessMAN-OFDMA PHY-specific parameters shall be included in the RNG-RSP message when an initial or periodic ranging message based on code division multiple access (CDMA) is received, in which case the RNG-RSP shall use the Initial Ranging CID.

Ranging code attributes
Indicates the OFDMA time symbols reference, subchannel reference, and frame number used to transmit the ranging code, and the ranging code index that was sent by the SS.

The RNG-RSP is directed to the SS if it is sent on the Basic CID of the SS or if the RNG-RSP contains the MAC address of the SS, or, in the case of OFDMA, if the RNG-RSP contains CDMA-code parameters specifying the code sent by the SS.

When a BS sends a RNG-RSP message in response to a RNG-REQ message containing serving BSID, the BS may include the TLV parameter Service Level Prediction in the RNG-RSP message.

The service level prediction value indicates the level of service the MS can expect from this BS. The following encodings apply:

0 = No service possible for this MS.
1 = Some service is available for one or several service flows authorized for the MS.
2 = For each authorized service flow, a MAC connection can be established with QoS specified by the AuthorizedQoSParamSet.
3 = No service level prediction available.
A Service Level Prediction may be accompanied by a number of service flow encodings as specified in 11.13 sufficient to uniquely identify the AuthorizedQoSParamSet associated with the Service Level Prediction. If service flow encodings are included, then the Service Level Prediction response is specific to the presented AuthorizedQoSParamSet defined by the associated encodings. Included service flow encodings are restricted to the following parameters only:

- Global service class name.
- Service flow QoS parameter set encodings as defined in 11.13 so that the combination of global service class name and any service flow modifying parameters fully defines an AuthorizedQoSParamSet profile being assessed.
- Service flow identifier (SFID).

If individual AuthorizedQoSParamSet profiles are provided for multiple Service Level Predictions, then each Service Level Prediction is specific to its associated AuthorizedQoSParamSet profile and shall include only response options 0 or 2.

When a BS sends a RNG-RSP message in response to a RNG-REQ message containing Paging Controller ID or a Power Down Indicator, the BS shall include the following TLV parameter in the RNG-RSP message:

**Location Update Response**  
Response to idle mode location update request (refer to Table 585)

The following TLV shall be included only if the Location Update Response is set to 0x00 (Success of Idle Mode Location Update) and the Paging Information has changed.

**Paging Information (see 11.1.8.3)**  
New Paging Information assigned to MS.

The following TLV shall be included only if the Location Update Response = 0x00 (Success of Idle Mode Location Update) and if Paging Controller ID has changed.

**Paging Controller ID (see 11.1.8.2)**  
Paging Controller ID is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in idle mode.

The following TLV parameter shall be included in the RNG-RSP message when the MS is attempting to perform network reentry or HO and the target BS wishes to identify reentry process management messages that may be omitted during the current HO attempt:

**HO Process Optimization**  
Identifies reentry process management messages that may be omitted during the current HO attempt due to the availability of MS service and operational context information obtained by means that are beyond the scope of this standard, and the MS service and operational status post-HO completion. The target BS may elect to use MS service and operational information obtained over the backbone network to build and send unsolicited SBC-RSP and/or REG-RSP management messages to update MS operational information. The MS shall not enter normal operation with target BS until completing receiving all network reentry, MAC management message responses as indicated in HO process optimization.

The following parameter may be included in RNG-RSP message transmitted in response to RNG-REQ message containing MAC Hash Skip Threshold:
MAC Hash Skip Threshold
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC address hash of an MS for which the action code for the MS is 00 (No Action Required).

The following TLV parameter shall be included in the RNG-RSP message when the periodic ranging in sleep operation completes and the serving BS decides to assign a new SLPID for the MS:

SLPID_Update (see 11.1.7.2)
The SLPID_Update is a compound TLV value that provides a shorthand method for changing the SLPID used by the MS during sleep mode operation. The SLPID_Update TLV specifies new SLPID replacing old SLPID.

The following parameter may be included in RNG-RSP message by the BS to define and/or activate/deactivate power saving class of type I, type II and type III. In case of HO, those TLVs are used only to define the Power Saving Class.

Power_Saving_Class_Parameters (see Table 585)
Unified TLV encoding for Power Saving Class Parameters (see Table 585).

The following TLV parameter may be included in RNG-RSP message transmitted the BS permits an activation of power saving class. This TLV indicates the enabled action that MS performs upon reaching trigger condition in sleep mode.

Enabled-Action-Triggered
Indicates possible action upon reaching trigger condition

The following TLV parameter shall be included in the RNG-RSP message when a BS sends RNG-RSP message as a reply to the RNG-REQ message from an MS which is performing initial ranging during HO and for which the BS has a current HO ID value:

HO_ID
Optional ID assigned for use in initial ranging to the target BS once this BS is selected as the target BS (see 11.5).

The following TLV parameter shall be included for the BS to notify the MS of known future next periodic ranging for the MS with its serving BS:

Next Periodic Ranging
Indicates the Frame Offset for the next periodic ranging opportunity. This value shall be set to zero to indicate that there has been DL traffic addressed to the MS.

The following parameter, necessary to expedite security authentication, shall be included in the RNG-RSP message when the BS notifies the MS through the HO Process Optimization TLV that the PKM-REQ/RSP sequence may be omitted for the current HO reentry attempt, or when the BS wishes to acknowledge a valid HMAC/CMAC Tuple in the acknowledged RNG-REQ management message:

HMAC/CMAC Tuple (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.
The following TLV parameters may be included in an unsolicited RNG-RSP message:

**Rendezvous time**
This is the offset, measured in units of frame duration, when the BS is expected to provide a non-contention-based ranging opportunity for the MS. The offset is calculated from the frame where RNG-RSP message is transmitted. The BS is expected to provide the non-contention-based ranging opportunity at the frame specified by the rendezvous time parameter.

**CDMA code**
A unique code assigned to the MS, to be used for dedicated ranging. The code is from the initial ranging codeset.

**Transmission Opportunity Offset**
A unique transmission opportunity assigned to the MS, to be used for dedicated ranging, in units of symbol duration.

### 6.3.2.3.7 REG-REQ (registration request) message

An REG-REQ shall be transmitted by an SS at initialization. An SS shall generate REG-REQs in the form shown in Table 45.

**Table 45—REG-REQ message format**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>REG-REQ_Message_Format() {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 6</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

An SS shall generate REG-REQs including the following parameters if authentication is supported:

**Primary Management CID (in the generic MAC header)**
The connection identifier in the generic MAC header is the Primary Management CID for this SS, as assigned in the RNG-RSP message.

All other parameters are coded as TLV tuples.

The REG-REQ shall contain the following TLVs:

**Hashed Message Authentication Code (HMAC)/CMAC Tuple**
Shall be the final attribute in the message’s TLV attribute list (11.1.2.1).

For PMP operation, the REG-REQ shall contain the following TLVs:

**CID Support (11.7.6)**
For PMP operation with OFDMA the REG-REQ may contain the following TLVs:

SS management support (11.7.2)
IP management mode (11.7.3)

For PMP operation with OFDM the REG-REQ shall contain the following TLVs:

SS management support (11.7.2)
IP management mode (11.7.3)

The REG-REQ may contain the following TLVs:

IP version (11.7.4)
SS capabilities encodings (11.7.8)
Vendor ID encoding (11.1.5)
Vendor-specific information (11.1.6)
Convergence Sublayer capabilities (11.7.7)
ARQ Parameters (11.7.1)
ARQ and fragmentation parameters desired by the SS for establishing the secondary management connection. When the TLV is not supplied, the SS is indicating its desire to not support ARQ on the connection. For purposes of the parameter negotiation dialog, the parameters supplied in this message are equivalent to those supplied in the DSA-REQ message.

For an MS supporting HO, the REG-REQ (on initial network entry) shall contain the following TLVs:

Handover supported field (11.7.12.5)
Mobility parameters support (11.7.13)

For an MS supporting HO, the REG-REQ (on initial network entry) shall contain the following TLV:

HO Process Optimization MS Timer (11.7.12.2)

The REG-REQ may contain the following TLV:

MAC header and extended subheader support (11.7.21)
BS switching timer (11.7.12.7)
Extended capability (11.7.8.11)

The following TLV may be added if the MS supports H-FDD:

H-FDD sleep capabilities (11.7.8.10)

6.3.2.3.8 REG-RSP (registration response) message

A REG-RSP shall be transmitted by the BS in response to received REG-REQ.

To provide for flexibility, the message parameters following the response field shall be encoded in a TLV format.

A BS shall generate REG-RSPs in the form shown in Table 46, including both of the following parameters:
CID (in the generic MAC header)
The connection identifier in the generic MAC header is the Primary Management CID for this SS.

Response
A 1 byte quantity with one of the two values:
  0 = OK
  1 = Message authentication failure

Table 46—REG-RSP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>

<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

For the OFDM PHY, the REG-RSP shall contain the following TLVs:

SS management support (11.7.2)
Response to REG-REQ indicating the mode of SS management operation.

Secondary Management CID (11.7.5)
Present only if the SS has indicated in the REG-REQ that it is a managed SS.

When the Secondary Management CID is present, the following UL QoS parameters may be also included in the message:

- Traffic Priority (11.13.5)
- Maximum Sustained Traffic Rate (11.13.6)
- Minimum Reserved Traffic Rate (11.13.8)
- Maximum Latency (11.13.13)

IP management mode (11.7.3)
Response to REG-REQ indication of whether the requester wishes to accept IP-based traffic on the secondary management connection, once the initialization process has completed.

The REG-RSP shall contain the following TLV if authentication is supported:

HMAC/CMAC Tuple (11.1.2.1)
The HMAC/CMAC Tuple attribute shall be the final attribute in the message’s TLV attribute list.

The REG-RSP may contain the following TLVs:
SS capabilities encodings (11.7.8)
Response to the capabilities of the requester provided in the REG-REQ. Included in the response if the request included capabilities information. The response indicates whether the capabilities may be used. If a capability is not recognized, the response indicates that this capability shall not be used by the requester. Capabilities returned in the REG-RSP shall not be set to require greater capability of the requester than is indicated in the REG-REQ.

IP Version (11.7.4)
Vendor ID Encoding (of the responder; 11.1.5)
Vendor-specific information (11.1.6)
Included if the RNG-REQ contained the Vendor ID Encoding of the requestor.

Convergence Sublayer capabilities (11.7.7)
Response to the capabilities of the requester provided in the REG-REQ. Included in the response if the request included Convergence Sublayer Capabilities information. The response indicates whether the capabilities may be used. If a capability is not recognized, the response indicates that this capability shall not be used by the requester. Capabilities returned in the REG-RSP shall not be set to require greater capability of the requester than is indicated in the REG-REQ.

ARQ Parameters (11.7.1)
ARQ and fragmentation parameters specified by the BS to complete ARQ parameter negotiation for the secondary management connection. This information is only included in the message if ARQ parameters were supplied by the SS in the original REG-REQ message. For purposes of the parameter negotiation dialog, the parameters supplied in this message are equivalent to those supplied in the DSA-RSP message.

For mobile stations, when the information is available to create the CID update TLV, the target BS shall include the CID_update and SAID_update TLVs in the REG-RSP for an MS recognized by the target BS as performing HO, network reentry from idle mode or location update for MBS update. The BS may include the Compressed CID Update TLV instead of the CID_update TLV in REG-RSP message if the CID update procedure is required. The target BS recognizes an MS performing location update for MBS update by the presence of a Paging Controller ID and Ranging Purpose Indication with Bit 4 set to 1 in the RNG-REQ message.

CID_update
The CID_update is a compound TLV value that provides a shorthand method for replacing the active connections used by the MS in its previous serving BS. Each CID_update TLV specifies a CID in the target BS that shall replace a CID used in the previous serving BS. Multiple instances of CID_update may occur in the REG-RSP to facilitate recreating and reassigning admitted or active service flows for the MS from its previous serving BS. If any of the service flow parameters change, then those service flow parameter encoding TLVs that have changed will be added. If the BS cannot reestablish a particular service flow, it shall not include an instance of CID_update for that service flow.

These TLVs enable the target BS to renew connections used in the previous serving BS, but with different service flow management encodings settings.

Compressed CID_update
The Compressed CID_update TLV also provides a method for replacing the active connections used by the MS in its previous serving BS as CID update TLV. It can diminish the length of REG-RSP message.
SAID_update
The SAID_update is a compound TLV value that provides a shorthand method for renewing active SAs used by the MS in its previous serving BS. The TLVs specify SAID in the target BS that shall replace active SAID used in the previous serving BS. Multiple iterations of these TLVs may occur in the REG-RSP suitable to recreating and reassigning all active Security Associations for the MS from its previous serving BS including Primary, Dynamic and Static SAIDs. If any of the Security Associations parameters change, then those Security Associations parameters encoding TLVs that have changed will be added.

When a BS has Provisioned service flows to transmit to an MS, the BS shall include the following:

Total number of provisioned service flow TLV (11.7.18)

The REG-RSP may contain the following TLV:

MAC header and extended subheader support (11.7.21)
Handover Indication Readiness Timer (11.7.12.6)
Extended capability (11.7.8.11)

For an MS supporting HO, the REG-RSP (on initial network entry) shall contain the following TLVs:

Handover supported field (11.7.12.5)
System Resource_Retain_Time (11.7.12.1)
Mobility parameters support (11.7.13)

For an MS supporting HO, the REG-RSP on initial network entry shall contain the following TLVs:

HO Process Optimization MS Timer (11.7.12.2)
MS Handover Retransmission Timer (11.7.12.3)
Handover Indication Readiness Timer (11.7.12.6)

The following TLV may be added if the MS supports H-FDD:

H-FDD sleep capabilities (11.7.8.10)

6.3.2.3.9 Privacy key management (PKM) messages (PKM-REQ/PKM-RSP)
PKM employs two MAC message types: PKM-REQ (PKM request) and PKM-RSP (PKM response), as described in Table 47.

Table 47—PKM MAC messages

<table>
<thead>
<tr>
<th>Type value</th>
<th>Message name</th>
<th>Message description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>PKM-REQ</td>
<td>Privacy key management request [SS -&gt; BS]</td>
</tr>
<tr>
<td>10</td>
<td>PKM-RSP</td>
<td>Privacy key management response [BS -&gt; SS]</td>
</tr>
</tbody>
</table>

These MAC management message types distinguish between PKM requests (SS-to-BS) and PKM responses (BS-to-SS). Each message encapsulates one PKM message in the management message payload.
PKM protocol messages transmitted from the SS to the BS shall use the form shown in Table 48. They are transmitted on the SSs primary management connection.

Table 48—PKM-REQ message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>PKM-REQ_Message_Format() {</td>

<td>8</td>
<td></td>
</tr>
<tr>
<td>TLV Encoded Attributes</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

PKM protocol messages transmitted from the BS to the SS shall use the form shown in Table 49. They are transmitted on the SS’s primary management connection. However, the PKMv2 Group-Key-Update-Command message for the GTEK update mode shall be carried on the Broadcast connection.

Table 49—PKM-RSP message format

<table>

</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The parameters shall be as follows:

**Code**

The Code field is one byte and identifies the type of PKM packet. When a packet is received with an invalid code, it shall be silently discarded. The code values are defined in Table 50.

**PKM Identifier**

The Identifier field is one byte. An SS uses the ID to match a BS response to the SS requests. In the case of a 3-way SA-TEK procedure, however, a BS uses it to match an SS response to the BS challenges.

The SS shall increment (modulo 256) the Identifier field whenever it issues a new PKM message. In PKMv1, a “new” message is an Authorization Request or Key Request that is not a retransmission being sent in response to a Timeout event. In PKMv2, a PKMv2 RSA-Request,
PKMv2 SA-TEK-Challenge, or PKMv2 Key-Request message is a “new” message. For retransmissions, the Identifier field shall remain unchanged.

The Identifier field in PKMv2 EAP-Transfer messages and Authentication Information messages, which is redundant and does not affect any response messaging, shall be set to zero. The Identifier field in a BS’s PKM-RSP message shall match the Identifier field of the PKM-REQ message the BS is responding to. The Identifier field in TEK Invalid messages and PKMv2 TEK Invalid messages, which are not sent in response to PKM-REQs, shall be set to zero. The Identifier field in unsolicited Authorization Invalid messages shall be set to zero. The Identifier field in PKMv2 Group-Key-Update-Command messages, which are used to distribute the updated group traffic encryption key (GTEK) and traffic keying material, shall be set to zero.

On reception of a PKM-RSP message, the SS associates the message with a particular state machine (the Authorization state machine in the case of Authorization Replies, Authorization Rejects, and Authorization Invalids for the PKMv1, PKMv2 RSA Reply, PKMv2 RSA Reject, PKMv2 EAP Transfer, PKMv2 SA-TEK-Challenge, PKMv2 SA-TEK-Response for the PKMv2; a particular TEK state machine in the case of Key Replies, Key Rejects, and TEK Invalids the PKMv1, PKMv2-Key-Reply, PKMv2-Key-Reject, PKMv2 TEK-Invalids, and PKMv2 Group-Key-Update-Command messages for the PKMv2).

In PKMv1, an SS shall keep track of its latest ID.

An SS shall keep track of the IDs of its latest, pending Key Request for each SA. The SS shall discard Key Reply and Key Reject messages with Identifier fields not matching those of the pending Key Request messages.

In PKMv2, both an SS and a BS shall keep track of their latest ID.

An SS shall keep track of the ID of its latest, pending PKMv2 RSA-Request. The SS shall discard PKMv2 RSA-Reply and PKMv2 RSA-Reject messages with Identifier fields not matching that of the pending PKMv2 RSA-Request. Moreover, a BS shall keep it, pending PKMv2 RSA-Reply. The BS shall discard PKMv2 RSA-Acknowledgement messages with Identifier fields not matching that of the pending PKMv2 RSA-Reply.

A BS shall keep track of the ID of its latest, pending PKMv2 SA-TEK-Challenge. The BS shall discard PKMv2 SA-TEK-Request messages with Identifier fields not matching that of the pending PKMv2 SA-TEK-Challenge. In addition, an SS shall keep it, pending PKMv2 SA-TEK-Request. The SS shall discard PKMv2 SA-TEK-Reply messages with Identifier fields not matching that of the pending PKMv2 SA-TEK-Request.

An SS shall keep track of the ID of its latest, pending PKMv2 Key-Request. The SS shall discard PKMv2 Key-Reply and PKMv2 Key-Reject messages with Identifier fields not matching that of the pending PKMv2 Key-Request.

**Attributes**

PKM attributes carry the specific authentication, authorization, and key management data exchanged between client and server. Each PKM packet type has its own set of required and optional attributes. Unless explicitly stated, there are no requirements on the ordering of attributes within a PKM message. The end of the list of attributes is indicated by the LEN field of the MAC PDU header.

</tbody>
</table>
Auth Invalid and Auth Info messages may be used in PKMv1 and PKMv2.

Formats for each of the PKM messages are described in the following subclauses. The descriptions list the PKM attributes contained within each PKM message type. The attributes themselves are described in 11.9. Unknown attributes shall be ignored on receipt and skipped over while scanning for recognized attributes.

The BS shall silently discard all requests that do not contain ALL required attributes. The SS shall silently discard all responses that do not contain ALL required attributes.

### 6.3.2.3.9.1 SA Add message

The SA Add message is sent by the BS to the SS to establish one or more additional SAs.

Code: 3

Attributes are shown in Table 51.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>Authorization key (AK) sequence number.</td>
</tr>
<tr>
<td>(one or more) SA-Descriptor(s)</td>
<td>Each compound SA-Descriptor attribute specifies an SA identifier (SAID) and additional properties of the SA.</td>
</tr>
<tr>
<td>HMAC-Digest</td>
<td>Keyed secure hash algorithm (SHA) message.</td>
</tr>
</tbody>
</table>

The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.

### 6.3.2.3.9.2 Auth Request (authorization request) message

Code: 4

---

Table 50—PKM message codes (continued)

<table>
<thead>
<tr>
<th>Code</th>
<th>PKM message type</th>
<th>MAC management message name</th>
</tr>
</thead>
<tbody>
<tr>
<td>33</td>
<td>MIH Comeback Response</td>
<td>PKM-RSP</td>
</tr>
<tr>
<td>34–255</td>
<td>Reserved</td>
<td></td>
</tr>
</tbody>
</table>
Attributes are shown in Table 52.

**Table 52—Auth Request message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>SS-Certificate</td>
<td>Contains the SS’s X.509 user certificate.</td>
</tr>
<tr>
<td>Security-Capabilities</td>
<td>Describes requesting SS’s security capabilities.</td>
</tr>
<tr>
<td>SAID</td>
<td>SS’s Primary SAID equal to the Basic CID.</td>
</tr>
</tbody>
</table>

The SS-Certificate attribute contains an X.509 SS certificate (see 7.6) issued by the SS’s manufacturer. The SS’s X.509 certificate is a public-key certificate that binds the SS’s identifying information to its RSA public key in a verifiable manner. The X.509 certificate is digitally signed by the SS’s manufacturer, and that signature can be verified by a BS that knows the manufacturer’s public key. The manufacturer’s public key is placed in an X.509 certification authority (CA) certificate, which in turn is signed by a higher level CA.

The Security-Capabilities attribute is a compound attribute describing the requesting SS’s security capabilities. This includes the data encryption and data authentication algorithms the SS supports.

An SAID attribute contains a Primary SAID. In this case, the provided SAID is the SS’s Basic CID, which is equal to the Basic CID assigned to the SS during initial ranging.

**6.3.2.3.9.3 Auth Reply (authorization reply) message**

Sent by the BS to a client SS in response to an Auth Request message, the Auth Reply message contains an AK, the key’s lifetime, the key’s sequence number, and a list of SA-Descriptors identifying the Primary and Static SAs that the requesting SS is authorized to access and their particular properties (e.g., type, cryptographic suite). The AK shall be encrypted with the SS’s public key. The SA-Descriptor list shall include a descriptor for the Basic CID reported to the BS in the corresponding Auth Request message. The SA-Descriptor list may include descriptors of Static SAIDs that the SS is authorized to access.

The Auth Reply message may also contain PKM configuration settings that override the default timer values.

Code: 5

Attributes are shown in Table 53.

**Table 53—Auth Reply message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTH-Key</td>
<td>AK, encrypted with the target client SS’s public key.</td>
</tr>
<tr>
<td>Key-Lifetime</td>
<td>AK’s active lifetime.</td>
</tr>
</tbody>
</table>
6.3.2.3.9.4 Auth Reject (authorization reject) message

The BS responds to an SS’s authorization request with an Auth Reject message if the BS rejects the SS’s authorization request.

Code: 6

Attributes are shown in Table 54.

Table 54—Auth Reject message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for rejection of authorization request.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display String providing reason for rejection of authorization request.</td>
</tr>
</tbody>
</table>

The Error-Code and Display-String attributes describe to the requesting SS the reason for the authorization failure.

6.3.2.3.9.5 Key Request message

Code: 7

For PMP operations, attributes are shown in Table 55.

Table 55—Key Request message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier.</td>
</tr>
<tr>
<td>HMAC-Digest</td>
<td>Keyed SHA message digest.</td>
</tr>
</tbody>
</table>

The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.
Inclusion of the keyed digest allows the BS to authenticate the Key Request message. The HMAC-Digest’s authentication key is derived from the AK or operator shared secret.

### 6.3.2.3.9.6 Key Reply message

Code: 8

Attributes are shown in Table 56.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security Association ID.</td>
</tr>
<tr>
<td>TEK-Parameters</td>
<td>“Older” generation of key parameters relevant to SAID.</td>
</tr>
<tr>
<td>TEK-Parameters</td>
<td>“Newer” generation of key parameters relevant to SAID.</td>
</tr>
<tr>
<td>HMAC-Digest</td>
<td>Keyed SHA message digest.</td>
</tr>
</tbody>
</table>

The TEK-Parameters attribute is a compound attribute containing all of the keying material corresponding to a particular generation of a SAID’s TEK. This would include the TEK, the TEK’s remaining key lifetime, its key sequence number, and the cipher block chaining (CBC) IV. The TEK is encrypted. See 11.9.8 for details.

At all times, the BS maintains two sets of active generations of keying material per SAID. (A set of keying material includes a TEK and its corresponding CBC IV.) One set corresponds to the “older” generation of keying material; the second set corresponds to the “newer” generation of keying material. The newer generation has a key sequence number one greater than (modulo 4) that of the older generation. Subclause 7.4.1 specifies BS requirements for maintaining and using a SAID’s two active generations of keying material.

The BS distributes to a client SS both generations of active keying material. Thus, the Key Reply message contains two TEK-Parameters attributes, each containing the keying material for one of the SAID’s two active sets of keying material.

The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the keyed digest allows the receiving client to authenticate the Key Reply message and ensure SS and BS have synchronized AKs. The HMAC-Digest attribute’s authentication key is derived from the AK. See 7.5 for details.

### 6.3.2.3.9.7 Key Reject message

Receipt of a Key Reject message indicates the receiving client SS is no longer authorized for a particular SAID.

Code: 9

Attributes are shown in Table 57.
The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the keyed digest allows the receiving client to authenticate the Key Reject message and ensure SS and BS have synchronized AKs. The HMAC-Digest attribute’s authentication key is derived from the AK. See 7.5 for details.

6.3.2.3.9.8 Authorization Invalid message

The BS may send an Authorization Invalid message to a client SS as

a) An unsolicited indication, or
b) A response to a message received from that SS.

In either case, the Authorization Invalid message instructs the receiving SS to reauthorize with its BS.

The BS sends an Authorization Invalid message in response to a Key Request message if

— The BS does not recognize the SS as being authorized (i.e., no valid AK associated with the requesting SS), or
— Verification of the Key Request message’s keyed message digest (in the HMAC-Digest attribute) failed, indicating a loss of AK synchronization between SS and BS.

Code: 10

Attributes are shown in Table 58.

### Table 57—Key Reject message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier.</td>
</tr>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for rejection of Key Request message.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string containing reason for Key Reject message.</td>
</tr>
<tr>
<td>HMAC-Digest</td>
<td>Keyed SHA message digest.</td>
</tr>
</tbody>
</table>

The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.

### Table 58—Authorization Invalid message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for invalid authorization.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string describing failure condition.</td>
</tr>
</tbody>
</table>
6.3.2.3.9.9 TEK Invalid message

The BS sends a TEK Invalid message to a client SS if the BS determines that the SS encrypted an UL PDU with a TEK (i.e., a SAID’s TEK key sequence number), contained within the received packet’s MAC header, that is out of the BS’s range of known, valid sequence numbers for that SAID.

Code: 11

Attributes are shown in Table 59.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security Association ID.</td>
</tr>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for TEK Invalid message.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string containing vendor-defined information.</td>
</tr>
<tr>
<td>HMAC-Digest</td>
<td>Keyed SHA message digest.</td>
</tr>
</tbody>
</table>

The HMAC-Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the keyed digest allows the receiving client to authenticate the TEK Invalid message and ensure SS and BS have synchronized AKs. The HMAC-Digest attribute’s authentication key is derived from the AK. See 7.5 for details.

6.3.2.3.9.10 Auth Info (authentication information) message

The Auth Info message contains a single CA-Certificate attribute, containing an X.509 CA certificate for the manufacturer of the SS. The SS’s X.509 user certificate shall have been issued by the CA identified by the X.509 CA certificate.

Auth Info messages are strictly informative; while the SS shall transmit Auth Info messages as indicated by the Authentication state model (7.2.1.5), the BS may ignore them.

Code: 12

Attributes are shown in Table 60.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>CA-Certificate</td>
<td>Certificate of manufacturer CA that issued SS certificate.</td>
</tr>
</tbody>
</table>

The CA-Certificate attribute contains an X.509 CA certificate for the CA that issued the SS’s X.509 user certificate. The external CA issues these CA certificates to SS manufacturers.
6.3.2.3.9.11 PKMv2 RSA-Request message

A client MS sends a PKMv2 RSA-Request message to the BS in order to request mutual authentication in the RSA-based authorization.

Code: 13

Attributes are shown in Table 61.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MS_Random</td>
<td>A 64-bit random number generated in the MS</td>
</tr>
<tr>
<td>MS_Certificate</td>
<td>Contains the MS’s X.509 user certificate</td>
</tr>
<tr>
<td>SAID</td>
<td>MS’s Primary SAID equal to the Basic CID</td>
</tr>
<tr>
<td>SigSS</td>
<td>An RSA signature over all the other attributes in the message</td>
</tr>
</tbody>
</table>

The MS-certificate attribute contains an X.509 MS certificate (see 7.6) issued by the MS’s manufacturer. The MS’s X.509 certificate is as defined in 6.3.2.3.9.2.

The SigSS attribute indicates a RSA signature over all the other attributes in this message, and the MS’s private key is used to make a RSA signature.

6.3.2.3.9.12 PKMv2 RSA-Reply message

Sent by the BS to a client MS in response to a PKMv2 RSA-Request message, the PKMv2 RSA-Reply message contains an encrypted pre-primary authorization key (pre-PAK), the key’s lifetime, and the key’s sequence number. The pre-PAK shall be encrypted with the MS’s public key. The MS_Random number is returned from the PKMv2 RSA-Request message, along with a random number supplied by the BS, thus enabling assurance of key liveness.

Code: 14

Attributes are shown in Table 62.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MS_Random</td>
<td>A 64-bit random number generated in the MS</td>
</tr>
<tr>
<td>BS_Random</td>
<td>A 64-bit random number generated in the BS</td>
</tr>
<tr>
<td>Encrypted pre-PAK</td>
<td>RSA-OAEP-Encrypt(PubKey(MS), pre-PAK</td>
</tr>
<tr>
<td>Key Lifetime</td>
<td>PAK aging timer</td>
</tr>
</tbody>
</table>
The SigBS attribute indicates a RSA signature over all the other attributes in this message, and the BS’s private key is used to make a RSA signature.

### 6.3.2.3.9.13 PKMv2 RSA-Reject message

The BS responds to an SS’s authorization request with a PKMv2 RSA-Reject message if the BS rejects the SS’s authorization request. When an MS receives this message, an MS may retransmit the PKMv2 RSA-Request message or quit RSA-based mutual authentication.

**Code:** 15

Attributes are shown in Table 63.

### Table 63—PKMv2 RSA-Reject message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>PAK sequence number</td>
</tr>
<tr>
<td>BS_Certificate</td>
<td>Contains the BS’s X.509 certificate</td>
</tr>
<tr>
<td>SigBS</td>
<td>An RSA signature over all the other attributes in the message</td>
</tr>
</tbody>
</table>

The Error-Code and Display-String attributes describe to the requesting MS the reason for the RSA-based authorization failure.

The SigBS attribute indicates a RSA signature over all the other attributes in this message, and the BS’s private key is used to make a RSA signature.

### 6.3.2.3.9.14 PKMv2 RSA-Acknowledgement message

The MS sends the PKMv2 RSA-Acknowledgement message to BS in response to a PKMv2 RSA-Reply message. Only if the value of the Auth Result Code attribute is failure, then the Error-Code and Display-String attributes can be included in this message.

**Code:** 16
Attributes are shown in Table 64.

**Table 64—PKMv2 RSA-Acknowledgement message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>BS_Random</td>
<td>A 64-bit random number generated in the BS</td>
</tr>
<tr>
<td>Auth Result Code</td>
<td>Indicates result (success or failure) of authorization procedure</td>
</tr>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for rejection of authorization request</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string providing reason for rejection of authorization request</td>
</tr>
<tr>
<td>SigSS</td>
<td>An RSA signature over all the other attributes in the message</td>
</tr>
</tbody>
</table>

The SigSS attribute indicates a RSA signature over all the other attributes in this message, and the SS’s private key is used to make a RSA signature.

**6.3.2.3.9.15 PKMv2 EAP-Start message**

EAP Start may be used to initiate an EAP session.

In the case of EAP reauthentication, the HMAC/CMAC Digest and Key Sequence Number attributes shall be included. At initial EAP authentication, these attributes are omitted.

The use of EAP Start to initiate an EAP session during initial network entry is optional. The BS shall not rely on its arrival in order to initiate an EAP session.

Code: 17

Attributes are shown in Table 65.

**Table 65—PKMv2 EAP-Start message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK</td>
</tr>
</tbody>
</table>

**6.3.2.3.9.16 PKMv2 EAP-Transfer message**

When an MS has an EAP payload received from an EAP method for transmission to the BS or when a BS has an EAP payload received from an EAP method for transmission to the MS, it encapsulates it in a PKMv2 EAP-Transfer message. In the case of reauthentication, the HMAC/CMAC Digest and Key Sequence Number attributes shall be included.

Code: 18
Attributes are shown in Table 66.

**Table 66—PKMv2 EAP-Transfer message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAP Payload</td>
<td>Contains the EAP authentication data, not interpreted in the MAC</td>
</tr>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK</td>
</tr>
</tbody>
</table>

The EAP Payload field carries data in the format described in section 4 of IETF RFC 3748.

**6.3.2.3.9.17 PKMv2 SA-TEK-Challenge message**

The BS transmits the PKMv2 SA-TEK-Challenge message as a first step in the 3-way SA-TEK handshake at initial network entry and at reauthorization. The BS shall send this message to the MS after finishing authorization procedure(s) selected by the negotiated Authorization Policy Support included in the SBC-REQ/RSP messages. It identifies an AK to be used, and includes a random number challenge to be returned by the MS in the PKMv2 SA-TEK-Request message.

Code: 20

Attributes are shown in Table 67.

**Table 67—PKMv2 SA-TEK-Challenge message attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>BS_Random</td>
<td>A freshly generated random number of 64 bits.</td>
</tr>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>AKID</td>
<td>Identifies the authorization key (this is the AKID of the new AK in the case of reauthentication).</td>
</tr>
<tr>
<td>Key lifetime</td>
<td>PMK lifetime, this attribute shall include only follows EAP-based authorization or EAP-based reauthorization procedures.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message authentication digest for this message.</td>
</tr>
</tbody>
</table>

The generation of the AK sequence number and the authorization key identifier (AKID) is defined in 7.2.2.4.1.

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate a PKMv2 SA-TEK-Challenge message. The HMAC/CMAC Digest attribute’s authentication keys are derived from the AK.
6.3.2.3.9.18 PKMv2 SA-TEK-Request message

The MS transmits the PKMv2 SA-TEK-Request message after receipt and successful HMAC Digest or CMAC value verification of an SA-Challenge tuple or PKMv2 SA-TEK-Challenge message from the BS. The PKMv2 SA-TEK-Request proves liveliness of the MS and its possession of the AK to the BS. If this message is being generated during initial network entry, then it constitutes a request for SA-Descriptors identifying the primary and static SAs and GSAs the requesting MS is authorized to access and their particular properties (e.g., type, cryptographic suite).

If this message is being generated following HO, then it constitutes a request for establishment (in the target BS) of TEKs, GTEKs, and group key encryption keys (GKEKs) for the MS and renewal of active primary, static and dynamic SAs and associated SAIDs used by the MS in its previous serving BS.

Code: 21

Attributes are shown in Table 68.

Table 68—PKMv2 SA-TEK-Request message attributes

<table>
<thead>
<tr>

<td>Security Negotiation Parameters</td>
<td>The requesting MS’s security capabilities (see 11.8.4)</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message authentication digest for this message</td>
</tr>
</tbody>
</table>

\(^a\)Receipt of a new BS random value in SA-TEK-Challenge indicates the beginning of a new handshake.

6.3.2.3.9.19 PKMv2 SA-TEK-Response message

The BS transmits the PKMv2 SA-TEK-Response message as a final step in the 3-way SA-TEK handshake.

Code: 22

Attributes are shown in Table 69.

Table 69—PKMv2 SA-TEK-Response message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MS_Random</td>
<td>The number received from the MS.</td>
</tr>
<tr>
<td>BS_Random</td>
<td>The random number included in the PKMv2 SA-TEK-Challenge message.</td>
</tr>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number</td>
</tr>
</tbody>
</table>
6.3.2.3.9.20 PKMv2 Key-Request message

An MS sends a PKMv2 Key-Request message to the BS to request new TEK and TEK-related parameters (GTEK and GTEK-related parameters for MBS) or GKEK and GKEK-related parameters for MBS.

Code: 23

Attributes are shown in Table 70.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier — GSAID for MBS</td>
</tr>
<tr>
<td>Nonce</td>
<td>A random number generated in an MS</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK</td>
</tr>
</tbody>
</table>

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate the PKMv2 Key-Request message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK.

6.3.2.3.9.21 PKMv2 Key-Reply message

The BS responds to an MS’s PKMv2 Key-Request message with a PKMv2 Key-Reply message.
Code: 24

Attributes are shown in Table 71.

Table 71—PKMv2 Key-Reply message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier — GSAID for MBS.</td>
</tr>
<tr>
<td>TEK-Parameters</td>
<td>“Older” generation of key parameters relevant to SAID — GTEK-Parameters for the MBS.</td>
</tr>
<tr>
<td>TEK-Parameters</td>
<td>“Newer” generation of key parameters relevant to SAID. — GTEK-Parameters for the multicast or broadcast service.</td>
</tr>
<tr>
<td>GKEK-Parameters</td>
<td>“Older” generation of GKEK-related parameters for MBS.</td>
</tr>
<tr>
<td>GKEK-Parameters</td>
<td>“Newer” generation of GKEK-related parameters for MBS.</td>
</tr>
<tr>
<td>Nonce</td>
<td>A same random number included in the PKMv2 Key-Request message.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK.</td>
</tr>
</tbody>
</table>

The TEK-Parameters and SAID attributes are as defined in 6.3.2.3.9.5.

The GKEK-Parameters attribute is a compound attribute containing all of the GKEK-related parameters corresponding to a GSAID. This would include the GKEK, the GKEK’s remaining key lifetime, and the GKEK’s key sequence number. The older generation of the GKEK-Parameters attribute is valid within the current lifetime, and the newer generation of the GKEK-Parameters attribute is valid within the next lifetime.

The BS shall always supply fresh (see 7.2.2.2.6) key material in the newer generation of Key Parameters in the PKMv2 Key-Reply message.

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate the PKMv2 Key-Reply message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK.

6.3.2.3.9.22 PKMv2 Key-Reject message

The BS responds to an MS’s PKMv2 Key-Request message with a PKMv2 Authorization-Reject message if the BS rejects the MS’s traffic keying material request.

Code: 25
Attributes are shown in Table 72.

### Table 72—PKMv2 Key-Reject message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier.</td>
</tr>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for rejection of the PKMv2 Key-Request message.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string containing reason for the PKMv2 Key-Request message.</td>
</tr>
<tr>
<td>Nonce</td>
<td>A same random number included in the PKMv2 Key Request message.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK.</td>
</tr>
</tbody>
</table>

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate the PKMv2 Key-Reject message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK.

#### 6.3.2.3.9.23 PKMv2 SA-Addition message

This message is sent by the BS to the SS to establish one or more additional SAs.

**Code:** 26

Attributes are shown in Table 73.

### Table 73—PKMv2 SA-Addition message attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>(one or more) SA-Descriptor(s)</td>
<td>Each compound SA-Descriptor attribute specifies a SAID and additional properties of the SA.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK.</td>
</tr>
</tbody>
</table>

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate the PKMv2 SA-Addition message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK.

#### 6.3.2.3.9.24 PKMv2 TEK-Invalid message

The BS sends a PKMv2 TEK-Invalid message to a client MS if the BS determines that the MS encrypted an UL PDU with a TEK (i.e., a SAID’s TEK key sequence number), contained within the received packet’s MAC header, that is out of the BS’s range of known, valid sequence numbers for that SAID.
Code: 27

Attributes are shown in Table 74.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number.</td>
</tr>
<tr>
<td>SAID</td>
<td>Security association identifier.</td>
</tr>
<tr>
<td>Error-Code</td>
<td>Error code identifying reason for PKMv2 TEK-Invalid message.</td>
</tr>
<tr>
<td>Display-String (optional)</td>
<td>Display string containing reason for the PKMv2 TEK-Invalid message.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message digest calculated using AK.</td>
</tr>
</tbody>
</table>

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list.

Inclusion of the HMAC/CMAC Digest attribute allows the MS and BS to authenticate the PKMv2 SA-Addition message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK.

### 6.3.2.3.9.25 PKMv2 Group-Key-Update-Command message

This message is sent by BS to refresh and push the GKEK-related parameters (for GKEK update mode) or the GTEK-related parameters (for GTEK update mode) to MSs served with the specific multicast service, broadcast service, or MBS.

Code: 28

Attributes are shown in Table 75.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key Sequence Number</td>
<td>AK sequence number for GKEK update mode, GKEK sequence number for GTEK update mode.</td>
</tr>
<tr>
<td>GSAID</td>
<td>Security association identifier.</td>
</tr>
<tr>
<td>Key Push Modes</td>
<td>Usage code of PKMv2 Group-Key-Update-Command message.</td>
</tr>
<tr>
<td>Key Push Counter</td>
<td>Counter one greater than that of older generation.</td>
</tr>
<tr>
<td>GTEK-Parameters</td>
<td>“Newer” generation of GTEK-related parameters relevant to GSAID. The GTEK-Parameters is the TEK-Parameters for multicast, broadcast service, or MBS.</td>
</tr>
<tr>
<td>GKEK-Parameters</td>
<td>“Newer” generation of GKEK-related parameters for multicast, broadcast service, or MBS.</td>
</tr>
<tr>
<td>HMAC/CMAC Digest</td>
<td>Message integrity code of this message.</td>
</tr>
</tbody>
</table>
Key Sequence Number attribute is the sequence number of the shared AK between an MS and a BS in this message for GKEK update mode. Key Sequence number is the GKEK sequence number in this message for GTEK update mode.

GSAID is SAID for the multicast group or the broadcast group. The type and length of the GSAID is equal to ones of the SAID.

There are two types in a PKMv2 Group-Key-Update-Command message, GKEK update mode and GTEK update mode. The former is used to update GKEK, and the latter is used to update GTEK for the multicast service, the broadcast service, or MBS. The Key Push Modes attribute indicates the usage code of a PKMv2 Group-Key-Update-Command message. The PKMv2 Group-Key-Update-Command message for the GKEK update mode is carried on the primary management connection, but, for the GTEK update mode, it is carried on the broadcast connection. A few of the attributes in a PKMv2 Group-Key-Update-Command message shall not be used according to this Key Push Modes attribute’s value. See 11.9.27 for details.

The Key Push Counter attribute is used to protect against replay attacks. This value is one greater than that of older generation. If the CMAC-Digest is included in this message, then the Key Push Counter may not be included.

A PKMv2-Group-Key-Update-Command message contains only the newer generation of key parameters, because this message informs an MS of key material to be used for the next lifetime. The GTEK-Parameters attribute is a compound attribute containing all of the keying material corresponding to a newer generation of a GSAID’s GTEK. This would include the GTEK, the GTEK’s remaining key lifetime, the GTEK’s key sequence number, the associated GKEK sequence number, and the cipher block chaining (CBC) initialization vector. The GTEK is TEK for the multicast group or the broadcast group. The type and length of the GTEK is equal to ones of the TEK. The GKEK (Group Key Encryption Key) can be randomly generated from a BS or a network entity (i.e., an ASA server or an MBS server). The GKEK should be identically shared within the same multicast group, broadcast service group or MBS group. The GTEK is encrypted with GKEK for the multicast service, broadcast service or MBS. GKEK parameters contain the GKEK encrypted by the KEK, GKEK sequence number, and GKEK lifetime. See 7.5.4.5 for details.

The HMAC/CMAC Digest attribute shall be the final attribute in the message’s attribute list. Inclusion of the keyed digest allows the receiving client to authenticate the PKMv2 Group-Key-Update-Command message. The HMAC/CMAC Digest attribute’s authentication key is derived from the AK for the GKEK update mode and GKEK for the GTEK update mode. See 7.2.2.2.9 for details.

6.3.2.3.9.26 MIH Initial Request message

The MS sends this message to the BS to deliver an MIH query encapsulated in an MIHF frame.

Code: 31

Attributes are shown in Table 76.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIHF frame type</td>
<td>Indicates the type of MIHF frame (11.1.11.2)</td>
</tr>
<tr>
<td>Delivery Method and Status Code</td>
<td>Indicates the delivery method of query response (11.9.39)</td>
</tr>
<tr>
<td>MIHF frame</td>
<td>The encapsulated MIHF query (11.1.11.1)</td>
</tr>
</tbody>
</table>
6.3.2.3.9.27 MIH Acknowledge

This message is sent by the BS to the MS to acknowledge a received MIH query encapsulated in an MIHF frame. The response to the query is sent in a later MIH Comeback Response message, and the MS uses a Query ID, received in this MIH Acknowledge message and associated with the MS Initial Request by virtue of the stateful nature of the MIH Acknowledge, to correlate the MIH Initial Request message query with the later response.

Code: 32

Attributes are shown in Table 77.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cycle</td>
<td>Indicates the delivery method of query response (11.9.38)</td>
</tr>
<tr>
<td>Query ID</td>
<td>Used to map query and query response (11.1.11.3)</td>
</tr>
<tr>
<td>Delivery Method and Status Code</td>
<td>Indicates the delivery method and status code (11.9.39)</td>
</tr>
</tbody>
</table>

6.3.2.3.9.28 MIH Comeback Response

The BS sends this message to the MS to deliver a query response encapsulated in an MIHF frame.

Code: 33

Attributes are shown in Table 78.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>MIHF frame type</td>
<td>Indicates the type of the included MIHF frame. Only included when an MIHF frame is present.</td>
</tr>
<tr>
<td>Query ID</td>
<td>Used to map query and query response (11.1.11.3).</td>
</tr>
<tr>
<td>Delivery Method and Status Code</td>
<td>Indicates the delivery method and status code (11.9.39).</td>
</tr>
<tr>
<td>MIHF frame</td>
<td>The encapsulated MIH response (11.1.11.1).</td>
</tr>
</tbody>
</table>
6.3.2.3.10 DSA-REQ message

A DSA-REQ message is sent by an SS or BS to create a new service flow.

Table 79—DSA-REQ message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSA-REQ_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 11</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

An SS or BS shall generate DSA-REQ messages in the form shown in Table 79, including the following parameters:

CID *(in the generic MAC header)*

SS’s primary management connection identifier.

Transaction ID

Unique identifier for this transaction assigned by the sender.

All other parameters are coded as TLV tuples.

A DSA-REQ message shall not contain parameters for more than one service flow unless the Group parameter Create/Change TLV (11.13.39) is used.

The DSA-REQ message shall contain the following:

Service Flow Parameters *(see 11.13)*

Specification of the service flow’s traffic characteristics and scheduling requirements.

Convergence Sublayer Parameter Encodings *(see 11.13.18)*

Specification of the service flow’s CS-specific parameters.

The DSA-REQ message shall contain the following parameter encoded as a TLV tuple if authentication is supported:

HMAC/CMAC Tuple *(see 11.1.2)*

The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.

6.3.2.3.10.1 SS-Initiated DSA

The SFID shall not be present in the DSA message; at the BS, the service flow within the DSA-REQ message shall be assigned a unique SFID, which shall be sent back in the DSA-RSP message. SS-initiated DSA-REQ messages may use the service class name in place of some, or all, of the QoS parameters.
6.3.2.3.10.2 BS-Initiated DSA

BS-initiated DSA-REQ messages may also include a CID. CIDs are unique within the MAC domain.

BS-initiated DSA-REQ messages for named service classes shall include the QoS parameter set associated with that service class. BS-initiated DSA-REQ messages shall also include the Target SAID for the service flow.

6.3.2.3.11 DSA-RSP message

A DSA-RSP message shall be generated in response to a received DSA-REQ message. The format of a DSA-RSP message shall be as shown in Table 80.

Table 80—DSA-RSP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSA-RSP_Message_Format()</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 12</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

CID (in the generic MAC header)
SS’s primary management connection identifier.

Transaction ID
Transaction ID from corresponding DSA-REQ.

Confirmation Code (see 11.13)
The appropriate confirmation code (CC) for the entire corresponding DSA-REQ.

All other parameters are coded as TLV tuples.

If the transaction is successful, the DSA-RSP message may contain the following:

Service Flow Parameters (see 11.13)
The complete specification of the service flow shall be included in the DSA-RSP if it includes a newly assigned CID or an expanded service class name.

CS Parameter Encodings (see 11.13.18)
Specification of the service flow’s CS-specific parameters.

Whether successful or unsuccessful, the message shall include the following parameter encoded as a TLV tuple if authentication is supported:
HMAC/CMAC Tuple (see 11.1.2.1)
The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.

6.3.2.3.11.1 SS-Initiated DSA

The BS’s DSA-RSP message for service flows that are successfully added shall contain an SFID. The DSA-RSP message for successfully admitted or active UL QoS parameter sets shall also contain a CID.

The BS’s DSA-RSP message shall also include the Target SAID for the service flow. If the corresponding DSA-REQ message uses the service class name (see 11.13.3) to request service addition, a DSA-RSP message shall contain the QoS parameter set associated with the named service class. If the service class name is used in conjunction with other QoS parameters in the DSA-REQ message, the BS shall accept or reject the DSA-REQ message using the explicit QoS parameters in the DSA-REQ message. If these service flow encodings conflict with the service class attributes, the BS shall use the DSA-REQ message values as overrides for those of the service class.

6.3.2.3.11.2 BS-Initiated DSA

If a DSA-RSP with status success is sent and Service Flow Parameter TLVs are included, the only Service Flow Parameter TLVs that may be included shall be those specified under 11.13.17 (ARQ TLVs for ARQ enabled connections).

6.3.2.3.12 DSA-ACK message

A DSA-ACK message shall be generated in response to a received DSA-RSP message. The format of a DSA-ACK message shall be as shown in Table 81.

Table 81—DSA-ACK message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSA-ACK_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 13</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID** *(in the generic MAC header)*
SS’s primary management connection identifier.

**Transaction ID**
Transaction ID from corresponding DSA-RSP.
Confirmation Code (see 11.13)
The appropriate CC for the entire corresponding DSA-RSP.

All other parameters are coded TLV tuples.

HMAC/CMAC Tuple (see 11.1.2)
The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.

6.3.2.3.13 DSC-REQ (DSC request) message

A DSC-REQ message is sent by an SS or BS to dynamically change the parameters of an existing service flow.

An SS or BS shall generate DSC-REQ messages in the form shown in Table 82, including the following parameters:

CID (in the generic MAC header)
SS’s primary management connection identifier.

Transaction ID
Unique identifier for this transaction assigned by the sender.

All other parameters are coded as TLV tuples.

Table 82—DSC-REQ message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSC-REQ_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 14</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

A DSC-REQ message shall not carry parameters for more than one service flow unless the Group parameter Create/Change TLV (11.13.39) is used.

A DSC-REQ message shall contain the following:

Service Flow Parameters (see 11.13)
Specifies the service flow’s new traffic characteristics and scheduling requirements. The admitted and active QoS parameter sets currently in use by the service flow. If the DSC message is successful and it contains service flow parameters, but does not contain replacement sets for both admitted and active QoS parameter sets, the omitted set(s) shall be set to null. The service flow parameters shall contain a SFID.

The DSC-REQ shall contain the following parameter encoded as a TLV tuple if authentication is supported:
HMAC/CMAC Tuple (see 11.1.2)

The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.

6.3.2.3.14 DSC-RSP (DSC response) message

A DSC-RSP shall be generated in response to a received DSC-REQ. The format of a DSC-RSP shall be as shown in Table 83.

Table 83—DSC-RSP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSC-RSP_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 15</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

CID (in the generic MAC header)

SS’s primary management connection identifier.

Transaction ID

Transaction ID from corresponding DSC-REQ.

Confirmation Code (see 11.13)

The appropriate CC for the corresponding DSC-REQ.

All other parameters are coded as TLV tuples.

If the transaction is successful, the DSC-RSP may contain the following:

Service Flow Parameters (see 11.13)

The complete specification of the service flow shall be included in the DSC-RSP only if it includes a newly assigned CID or an expanded service class name. If a service flow parameter set contained an UL admitted QoS parameter set and this service flow does not have an associated CID, the DSC-RSP shall include a CID. If a service flow parameter set contained a service class name and an admitted QoS parameter set, the DSC-RSP shall include the QoS parameter set corresponding to the named service class. If specific QoS parameters were also included in the classed service flow request, these QoS parameters shall be included in the DSC-RSP instead of any QoS parameters of the same type of the named service class.

CS Parameter Encodings (see 11.13.18)

Specification of the service flow’s CS-specific parameters.
Whether successful or unsuccessful, the message shall include the following parameter encoded as a TLV tuple if authentication is supported:

**HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.

### 6.3.2.3.15 DSC-ACK (DSC acknowledge) message

A DSC-ACK shall be generated in response to a received DSC-RSP. The format of a DSC-ACK shall be as shown in Table 84.

#### Table 84—DSC-ACK message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSC-ACK_Message_Format()</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID** *(in the generic MAC header)*

SS’s primary management connection identifier.

**Transaction ID**

Transaction ID from the corresponding DSC-REQ.

**Confirmation Code** *(see 11.13)*

The appropriate CC for the entire corresponding DSC-RSP.

All other parameters are coded TLV tuples.

**HMAC/CMAC Tuple** *(see 11.1.2)*

The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.
6.3.2.3.16 DSD-REQ message

A DSD-REQ is sent by an SS or BS to delete an existing service flow. The format of a DSD-REQ shall be as shown in Table 85.

Table 85—DSD-REQ message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSD-REQ_Message_Format()</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type 17</td>
<td>8</td>
<td>—</td>

<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID (in the generic MAC header)**
SS’s primary management connection identifier.

**Service Flow ID**
The SFID to be deleted.

**Transaction ID**
Unique identifier for this transaction assigned by the sender.

All other parameters are coded as TLV tuples.

**HMAC/CMAC Tuple** (see 11.1.2.1)
The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.
6.3.2.3.17 DSD-RSP message

A DSD-RSP shall be generated in response to a received DSD-REQ. The format of a DSD-RSP shall be as shown in Table 86.

**Table 86—DSD-RSP message format**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSD-RSP_Message_Format() {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 18</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>

<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td><em>variable</em></td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID (in the generic MAC header)**
SS’s primary management connection identifier.

**Service Flow ID**
SFID from the DSD-REQ to which this response refers.

**Transaction ID**
Transaction ID from the corresponding DSD-REQ.

**Confirmation Code (see 11.13)**
The appropriate CC for the corresponding DSD-REQ.

All other parameters are coded as TLV tuples.

**HMAC/CMAC Tuple (see 11.1.2)**
The HMAC/CMAC Tuple attribute contains a keyed message digest (to authenticate the sender). The HMAC Tuple attribute shall be the final attribute in the DSx message’s attribute list.
6.3.2.3.18 MCA-REQ (multicast polling assignment request) message

The MCA-REQ message is sent to an SS to assign it to or remove it from a multicast polling group. The format of the message is shown in Table 87.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCA-REQ_Message_Format()</td>
<td>—</td>
<td>—</td>

<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID** *(in the generic MAC header)*

SS’s primary management connection identifier.

**Transaction ID**

Unique identifier for this transaction assigned by the sender.

All other parameters are coded as TLV tuples.

**Multicast CID** *(see 11.10)*

**Assignment** *(see 11.10)*

6.3.2.3.19 MCA-RSP (multicast polling assignment response) message

The MCA-RSP is sent by the SS in response to a MCA-REQ. The message format shall be as shown in Table 88.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCA-RSP_Message_Format()</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 22</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Transaction ID</td>
<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID (in the generic MAC header)**
SS’s primary management connection identifier.

**Transaction ID**
Unique identifier for this transaction assigned by the sender.

**Confirmation Code**
Zero indicates the request was successful. Nonzero indicates failure.

#### 6.3.2.3.20 DBPC-REQ (DL burst profile change request) message

This message is not applicable to OFDMA PHY.

The DBPC-REQ message is sent by the SS to the BS on the SS’s Basic CID to request a change of the least robust DL burst profile used by the BS to transport data to the SS (i.e., the DL operational burst profile). Note that a change of DL burst profile may also be requested by means of a RNG-REQ message as defined in 6.3.2.3.5.

The DBPC-REQ message shall be sent at the current operational Data Grant Burst Type for the SS. If the SS detects changes in the channel conditions on the DL, the SS uses this message to request transition to a more appropriate Data Grant Burst Type. The message format shall be as shown in Table 89.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBPC-REQ_Message_Format() {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 23</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Reserved</td>
<td>4</td>
<td>Shall be set to zero</td>
</tr>
<tr>
<td>DIUC</td>
<td>4</td>
<td>—</td>
</tr>
<tr>
<td>Configuration Change Count</td>
<td>8</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**DIUC**
Data grant DIUC values. (PHY-specific: SC—Table 220, OFDM—Table 275, OFDMA—Table 322)

**Configuration Change Count**
Value of Configuration Change Count provided in DCD defining the burst profile associated with DIUC.

#### 6.3.2.3.21 DBPC-RSP (DL burst profile change response) message

This message is not applicable to OFDMA PHY.
The DBPC-RSP message shall be transmitted by the BS on the SS’s Basic CID in response to a DBPC-REQ message from the SS. If the DIUC parameter is the same as requested in the DBPC-REQ message, then the request was accepted. Otherwise, if the request is rejected, the DIUC parameter shall be the previous DIUC at which the SS was receiving DL data. The message format shall be as shown in Table 90.

### Table 90—DBPC-RSP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBPC-RSP_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 24</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>Reserved</td>
<td>4</td>
<td>Shall be set to zero</td>
</tr>
<tr>
<td>DIUC</td>
<td>4</td>
<td>—</td>
</tr>
<tr>
<td>Configuration Change Count</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

- **DIUC**
  - Data grant DIUC values. (PHY-specific: SC—Table 220, OFDM—Table 275, OFDMA—Table 322)

- **Configuration Change Count**
  - Value of Configuration Change Count provided in DCD defining the burst profile associated with DIUC.

### 6.3.2.3.22 RES-CMD (reset command) message

The RES-CMD message shall be transmitted by the BS on an SS’s Basic CID to force the SS to reset itself, reinitialize its MAC, and repeat initial system access. This message may be used if an SS is unresponsive to the BS or if the BS detects continued abnormalities in the UL transmission from the SS.

The RES-CMD message format is shown in Table 91.

### Table 91—RES-CMD message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES-CMD_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 25</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV encoded information</td>
<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>
The RES-CMD shall include the following parameter encoded as a TLV tuple if authentication is supported:

**HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.23 SBC-REQ (SS basic capability request) message

The SBC-REQ shall be transmitted by the SS during initialization. An SS shall generate SBC-REQ messages in the form shown in Table 92.

**Table 92—SBC-REQ message format**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBC-REQ_Message_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 26</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

An SS shall generate SBC-REQ messages including the following parameter:

**Basic CID (in the MAC header)**

The connection identifier in the MAC header is the Basic CID for this SS, as assigned in the RNG-RSP message.

All other parameters are coded as TLV tuples.

The Basic Capabilities Request contains the SS Capabilities Encodings (11.8) that are necessary to acquire NSP information and for effective communication with the SS during the remainder of the initialization protocols. NSP information is solicited in the SBC-REQ message when the SBC-REQ includes the SIQ TLV (11.8.9) with bit bit 0 set to 1.

The following parameter shall be included in the Basic Capability Request if the SS is intended to solicit NSP information:

**Service Information Query** (see 11.8.9)

The following parameter shall be included in the Basic Capabilities Request only if the SS is not intended to solicit NSP information:

**Physical Parameters Supported** (see 11.8.3)

The following parameters may be included if the SS is not intended to solicit NSP information:

- **Capabilities for construction and transmission of MAC PDUs** (see 11.8.2)
- **Security negotiation parameters** (see 11.8.4)
- **Visited NSP ID** (see 11.8.11)
- **Auth Type for EAP** (see 11.8.12)
- **MIH Capability Supported** (see 11.8.10)
**SDU MTU capability** (see 11.8.15)

**DL Coordinated Zone capability** (see 11.8.16)

The Basic Capability Request shall include the following parameter encoded as a TLV tuple if authentication has been completed:

**HMAC/CMAC Tuple** (see 11.1.2)

Either the HMAC Tuple or the CMAC Tuple shall be the final attribute in the message’s TLV attribute list. This attribute should be included in the message during HO reentry.

For FDD systems, the following parameter shall be included in the Basic Capabilities Request only if the SS is not intended to solicit NSP information:

**Bandwidth Allocation Support** (see 11.8.1)

### 6.3.2.3.24 SBC-RSP (SS basic capability response) message

The SBC-RSP shall be transmitted by the BS in response to a received SBC-REQ.

To provide flexibility, the message parameters following the Response field shall be encoded in a TLV format. See Table 93.

#### Table 93—SBC-RSP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBC-RSP_Message_Format() {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 27</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Attributes</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

A BS shall generate SBC-RSP messages in the form shown in Table 93, including both of the following parameters:

**CID (in the MAC header)**

The connection identifier in the MAC header is the Basic CID for this SS, as appears in the RNG-REQ message.

The following parameter may be included in the SBC-RSP.

**SDU MTU capability** (see 11.8.15)

NSP information is solicited in the SBC-REQ message when the SBC-REQ includes the SIQ TLV (11.8.9) with bit 0 set to 1.

If NSP information is solicited in the SBC-REQ, then the following parameters shall not be included in the SBC-RSP; otherwise the following parameters shall be included in the SBC-RSP if found in the SBC-REQ:
Physical Parameters Supported (see 11.8.3)

Bandwidth Allocation Support (see 11.8.1)

The BS response to the subset of SS capabilities present in the SBC-REQ message. The BS responds to the SS capabilities to indicate whether they may be used. If the BS does not recognize an SS capability, it may return this as “off” in the SBC-RSP.

Only capabilities set to “on” in the SBC-REQ may be set “on” in the SBC-RSP, as this is the handshake indicating that they have been successfully negotiated.

Security negotiation parameters (see 11.8.4)

HMAC/CMAC Tuple

Either the HMAC Tuple or the CMAC Tuple shall be the final attribute in the message’s TLV attribute list. This attribute should be included in the message during HO reentry (see 11.1.2).

If NSP information is not solicited in the SBC-REQ, then the capabilities for construction and transmission of MAC PDUs (see 11.8.2) include the following parameter; otherwise, the following parameter shall not be included in the SBC-RSP:

Maximum number of supported security association (see 11.8.4.6)

The following parameter may be included in the SBC-RSP:

SII-ADV Message Pointer (see 11.8.14)

If NSP information is solicited in the SBC-REQ and the BS is configured with a list of NSP IDs, then the NSP List TLV and, if requested, the Verbose NSP Name List TLV shall be included unless the message includes an SII-ADV Message Pointer TLV providing a pointer to an SII-ADV message in which these TLVs are sent; if the message does include an SII-ADV Message Pointer TLV, then these TLVs may be included:

NSP List (see 11.1.10.1)

Verbose NSP Name List (see 11.1.10.2)

Verbose NSP Name List shall only be included in the message if NSP List TLV is also included in the message, the verbose NSP names were solicited in the SIQ TLV and the BS is configured with a list of verbose NSP names.

If NSP information is not solicited in the SBC-REQ, then the following parameters may be included when solicited in the SBC-REQ message:

MIH Capability Supported (see 11.8.10)

If the Visited NSP ID TLV is found in the SBC-REQ, then the following parameter shall be included:

Visited NSP Realm (see 11.8.13)

6.3.2.3.25 CLK-CMP (clock comparison) message

In network systems with service flows carrying information that requires the SSs to reconstruct their network clock signals (e.g., DS1 and DS3), CLK-CMP messages shall be periodically broadcast by the BS. When these services are not supported by the SS, the implementation of the CLK-CMP message at the SS shall be optional. If provisioned to do so, the BS shall take a clock difference measurement at every periodic interval (within the tolerance of the 10 MHz reference defined in the definition of the Clock Comparison
Table 94—CLK-CMP message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLK-CMP_Message_Format() {</td>
<td>—</td>

</tr>
<tr>
<td>Comparison Value[i]</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

CLK-CMP messages shall include the following parameters where Clock ID, Sequence Number, and Clock Comparison Value (CCV) shall be repeated for each clock signal:

Clock Count
This 8-bit value shall be the number of CCVs included in the CLK-CMP message.

Clock ID
This 8-bit value shall be the unique identifier for each clock signal from which the CCVs are generated by the BS.

Sequence Number
This 8-bit value shall be incremented by one (modulo the field size, 256) by the BS whenever a new CLK-CMP message is generated. This parameter is used to detect packet losses.

Clock Comparison Value
This 8-bit value shall be the difference (modulo the field size, 256) between the following two reference clock signals: (1) a 10 MHz reference clock locked to the symbol clock of the airlink [such as a global positioning satellite (GPS) reference used to generate the symbol clock], and (2) an 8.192 MHz reference clock locked to the network clock.

6.3.2.3.26 DREG-CMD (de/reregister command) message

The DREG-CMD message shall be transmitted by the BS on an SS’s Basic CID to force the SS to change its access state. The BS may transmit the DREG-CMD message unsolicited or in response to a DREG-REQ message. Upon receiving a DREG-CMD message, the SS shall take the action indicated by the action code.
The format of the message is shown in Table 95.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DREG-CMD_Message_Format()</td>

<td>8</td>
<td>—</td>
</tr>
<tr>
<td>TLV encoded parameters</td>
<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The action code values and the corresponding actions are specified in Table 96.

<table>
<thead>
<tr>
<th>Action code (hexadecimal)</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>SS shall immediately terminate service with the BS and should attempt network entry at another BS.</td>
</tr>
<tr>
<td>01</td>
<td>SS shall listen to the current BS but shall not transmit until a RES-CMD message or DREG-CMD message with action code 02 or 03 is received.</td>
</tr>
<tr>
<td>02</td>
<td>SS shall listen to the current BS but only transmit on the basic and primary management connections.</td>
</tr>
<tr>
<td>03</td>
<td>SS shall return to normal operation and may transmit on any of its active connections.</td>
</tr>
<tr>
<td>04</td>
<td>This option is valid only in response to a DREG-REQ message with De-Registration Request Code = 0x00. The SS shall terminate current Normal Operations with the BS.</td>
</tr>
<tr>
<td>05</td>
<td>MS shall begin MS idle mode initiation. See 6.3.23.1.</td>
</tr>
<tr>
<td>06</td>
<td>This option is valid only in response to a DREG-REQ message with De-Registration Request Code = 0x01. The behavior of MS to this action code is described in 6.3.23.1.</td>
</tr>
<tr>
<td>07–0xFF</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The DREG-CMD message shall include the following parameters encoded as TLV tuples if authentication is supported:

**HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

When the DREG-CMD message is sent with action code 0x05, the following TLVs shall be included:

**Paging Information** (see 11.1.8.3)

The Paging Information TLV defines the PAGING CYCLE, PAGING OFFSET Paging-Group-ID and Paging Interval Length parameters to be used by the MS in IDLE mode.
Paging Controller ID (see 11.1.8.2)

The Paging Controller ID is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in idle mode. Paging Controller ID shall be set to BSID when a BS is acting as paging controller.

Idle Mode Retain Information

The Idle Mode Retain Information provided as part of this message is indicative only. Network reentry from idle mode process requirements may change at the time of actual reentry. For each bit location, a value of 0 indicates the information for the associated reentry management messages shall not be retained and managed, a value of 1 indicates the information for the associated reentry management message shall be retained and managed.

- **Bit 0**: Retain MS service and operational information associated with SBC-REQ/RSP messages.
- **Bit 1**: Retain MS service and operational information associated with PKM-REQ/RSP messages.
- **Bit 2**: Retain MS service and operational information associated with REG-REQ/RSP messages.
- **Bit 3**: Retain MS service and operational information associated with network address.
- **Bit 4**: Retain MS service and operational information associated with time of day.
- **Bit 5**: Retain MS service and operational information associated with TFTP messages.
- **Bit 6**: Retain MS state information (see 11.14).
- **Bit 7**: Consider Paging Preference of each service flow in resource retention. Bit 7 is meaningful when Bit 2 and Bit 6 have a value of 1. If Bit 2, Bit 6, and Bit 7 is 1, MS state information (see 11.14) is retained for service flows with positive Paging Preference. If Bit 2 and Bit 6 are 1 and Bit 7 is 0, MS state information (see 11.14) is retained for all service flows.

When the DREG-CMD message is sent with action code 0x05, the following TLVs may be included:

**MAC Hash Skip Threshold**

Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC Address hash of an MS for which the action code is 00 (No Action Required). If a BS receives the DREG-REQ message containing MAC Hash Skip Threshold TLV, the BS may include MAC Hash Skip Threshold TLV in the DREG-CMD message. If the value is set to 0xFF, a BS shall omit MAC Address hash of the MS with No Action Required for every MOB_PAG-ADV message. If the value is set to zero, BS shall include the MS MAC Address hash in every MOB_PAG-ADV message.

The DREG-CMD message may include the following parameters encoded as TLV tuples:

**REQ-duration**

Waiting value for the DREG-REQ message re-transmission (measured in frames) if this is included with action code 0x06 in DREG-CMD. If serving BS includes REQ-duration in a DREG-CMD message including an Action Code = 0x05, the MS may initiate an Idle Mode request through a DREG-REQ with Action Code = 0x01, request for MS De-Registration from serving BS and initiation of MS Idle Mode, at REQ-duration expiration.

6.3.2.3.27 DSX-RVD (DSx received) message

The DSX-RVD message shall be generated by the BS in response to an SS-initiated DSx-REQ to inform the SS that the BS has received the DSx-REQ message in a more timely manner than provided by the DSx-RSP.
message, which shall be transmitted only after the DSx-REQ is authenticated. The format of the DSX-RVD shall be as shown in Table 97.

Table 97—DSX-RVD message format

<table>
<thead>
<tr>
<th>Syntax</th>

<td>16</td>
<td></td>
</tr>
<tr>
<td>Confirmation Code</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID** *(in the generic MAC header)*  
SS’s primary management connection identifier.

**Transaction ID**  
Transaction ID from corresponding DSx-REQ.

**Confirmation Code** *(see 11.13)*  
The appropriate CC indicating the integrity of the corresponding DSx-REQ.

6.3.2.3.28 TFTP-CPLT (Config File TFTP complete) message

The TFTP-CPLT message shall be generated by a managed SS when it has successfully retrieved its configuration file from the provisioning server (see 6.3.9.12). If the SS does not need a configuration file, it shall send the TFTP-CPLT message to the BS anyway to indicate that it has completed initialization and is ready to accept services. The format of the TFTP-CPLT shall be as shown in Table 98.

Table 98—TFTP-CPLT message format

<table>

<td>variable</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID** *(in the generic MAC header)*  
SS’s primary management connection identifier.
The TFTP-CPLT shall include the following parameters encoded as a TLV tuple if authentication is supported:

**HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.29 TFTP-RSP (Config File TFTP complete response) message

The TFTP-RSP message shall be generated by the BS in response to a TFTP-CPLT message from the SS (see 6.3.9.12). The format of the TFTP-RSP shall be as shown in Table 99.

#### Table 99—TFTP-RSP message format

<td></td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Parameters shall be as follows:

**CID (in the generic MAC header)**

SS’s primary management connection identifier.

**Response**

A 1 byte quantity with one of the two values:

0 = OK

1 = Message authentication failure

### 6.3.2.3.30 ARQ-Feedback message

A system supporting ARQ shall be able to receive and process the ARQ-Feedback message.

The ARQ-Feedback message, as shown in Table 100, can be used to signal any combination of different ARQ ACKs (cumulative, selective, selective with cumulative). The message shall be sent on the appropriate basic management connection.
ARQ_Feedback_Payload field shall be either sent using this ARQ Feedback message or by packing ("piggybacking") the ARQ_Feedback_Payload as described in 6.3.3.4.3.

6.3.2.3.31 ARQ-Discard message

This message is applicable to ARQ-enabled connections only.

The transmitter sends this message when it wants to skip a certain number of ARQ blocks. The ARQ Discard message shall be sent as a MAC management message on the basic management connection of the appropriate direction. Table 101 shows the format of the discard message.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARQ_Feedback_Message_Format() {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 33</td>
<td>8</td>
<td>—</td>

<td>See 6.3.3.4.3.</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

6.3.2.3.32 ARQ-Reset message

This message is applicable to ARQ-enabled connections only.

The transmitter or the receiver may send this message. The message is used in a dialog to reset the parent connection’s ARQ transmitter and receiver state machines. The ARQ Reset message shall be sent as a MAC management message on the basic management connection of the appropriate direction. Table 102 shows the format of the reset message.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

<td>BSN</td>
<td>11</td>
<td>Sequence number of the last block in the transmission window that the transmitter wants to discard.</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>
For Transport CIDs, the Direction bits shall be set to 0b00 on transmission, and ignored on reception. For Secondary Management CIDs, the Direction bits shall be set to 0b01 or 0b10 as appropriate and other values shall cause the message to be treated as invalid and discarded on reception.

### 6.3.2.3.33 Channel Measurement REP-REQ/RSP (report request/response)

If the BS, operating in bands below 11 GHz, requires RSSI and CINR channel measurement reports, it shall send the Channel Measurement REP-REQ message. The Channel Measurement REP-REQ message shall additionally be used to request the results of the measurements the BS has previously scheduled. Table 103 shows the Channel Measurement REP-REQ message.

<table>
<thead>
<tr>
<th>Syntax</th>

</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The Channel Measurement REP-REQ message shall contain the following TLV encoded parameters:

**Report Request**
The Channel Measurement REP-RSP message shall be used by the SS to respond to the channel measurements listed in the received Channel Measurement REP-REQ messages. Where regulation mandates detection of specific signals by the SS, the SS shall also send a Channel Measurement REP-RSP message in an unsolicited fashion upon detecting such signals on the channel in which it is operating if mandated by regulatory requirements. The SS may also send a Channel Measurement REP-RSP message containing channel measurement reports, in an unsolicited fashion, or when other interference is detected above a threshold value. When specific signal detection by an SS is not mandated by regulation, the SS may indicate “Unmeasured. Channel Not Measured” (see 11.12) in the Channel Measurement REP-RSP message when responding to the Channel Measurement REP-REQ message from the BS. Table 104 shows the Channel Measurement REP-RSP message.

### Table 104—Channel Measurement REP-RSP message format

<table>
<thead>
<tr>

<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The Channel Measurement REP-RSP message shall contain the following TLV encoded parameters:

- **Report**
  - Compound TLV that shall contain the measurement Report in accordance with the Report Request (see 11.11).

Upon sending a Channel Measurement REP-RSP message, an SS shall reset all its measurement counters for each channel on which it reported.

### 6.3.2.3.34 FPC (fast power control) message

Power control shall be effected by the use of periodic ranging. In addition, the BS may adjust the power levels of multiple subscribers simultaneously with the FPC message. SSs shall apply the indicated change within the “FPC processing time.” If the SS cannot apply the commanded power correction (SS is already at maximum or minimum power), the SS shall send a RNG-REQ message with the Ranging Anomalies parameter. FPC shall be sent on the Broadcast CID. This message shall only apply to OFDM, and OFDMA PHY specifications. See Table 105. Implementation of the FPC message at the BS is optional.

The SS shall apply the FPC power correction within the time interval given by “FPC processing time” (see Table 525) from the start of frame \( n + 1 \) (where frame \( n \) contains the FPC) to the end of frame \( n + 1 \), depending on the occurrence of the next scheduled UL allocation. If the UL allocation scheduled for this SS starts after the FPC processing time in frame \( n + 1 \) the correction shall be applied to this allocation. Otherwise the correction shall apply to the subsequent frames.
Table 105—FPC message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>

<td>16</td>
<td>—</td>
</tr>
<tr>
<td>Power adjust</td>
<td>8</td>
<td>—</td>
</tr>
</tbody>
</table>

Number of stations
Number of CID and Power Adjust tuples contained in this message.

Power measurement frame
The 8 LSBs of the frame number in which the BS measured the power corrections referenced in the message.

Basic CID
Basic connection identifier associated with the SS.

Power Adjust
Signed integer, which expresses the change in power level (in multiples of 0.25 dB) that the SS shall apply to its current transmission power.

6.3.2.3.35 AAS-FBCK-REQ/RSP (AAS channel feedback request/response) messages
The AAS-FBCK-REQ message shall be used by a system supporting AAS. This message serves to request channel measurement that will help in adjusting the direction of the adaptive array. See Table 106.

Table 106—AAS-FBCK-REQ message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAS-FBCK-REQ_Message_Format() {}</td>

<td>See 8.3 or 8.4.</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

6.3.2.3.36 AAS_Beam_Select message

The AAS_Beam_Select message may be used by a system supporting AAS. This message may be sent by the SS in an unsolicited manner, to inform the BS about the preferred beam for the AAS SS sending this message. The AAS_Beam_Select message shall be sent on the basic CID. See Table 108.

### Table 108—AAS_Beam_Select message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

<td>—</td>
</tr>
<tr>
<td>Reserved</td>
<td>2</td>
<td>Shall be set to zero.</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**AAS beam index**

This index shall correspond to the direction to which the AAS beam is pointing during the AAS_DLFP() preferred by the SS (see 8.4.4.7).

For systems supporting mobility, the parameter “Allow AAS Beam Select Messages” in the UCD channel encoding TLV messages can be configured to indicate that these messages should not be sent by any MS, and the default value of “Allow AAS Beam Select Messages” is 1.
6.3.2.3.37 DREG-REQ (SS deregistration request) message

An SS may send a DREG-REQ message to a BS in order to notify the BS of SS deregistration from normal operation service from the BS. The format of the message is shown in Table 109.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DREG-REQ message format()</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 49</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>De-registration_Request_Code</td>
<td>8</td>
<td>0x00 = SS deregistration request from BS and network 0x01 = Request for MS deregistration from serving BS and initiation of MS idle mode 0x02 = Response for the Unsolicited MS deregistration initiated by the BS. 0x03 = Reject for the unsolicited DREG-CMD with action code 0x05 (idle mode request) by the BS, This code is applicable only when MS has a pending UL data to transmit. 0x04–0xFF = Reserved</td>
</tr>
<tr>
<td>TLV encoded parameters</td>
<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

An SS shall generate DREG-REQ messages including the following parameters:

**De-registration_Request_Code**
Request code identifying the type of deregistration request:

- 0x00 = SS deregistration request from BS and network
- 0x01 = Request for MS deregistration from serving BS and initiation of MS idle mode
- 0x02 = Response for the Unsolicited MS deregistration initiated by the BS.
- 0x03 = Reject for the unsolicited DREG-CMD with action code 0x05 (idle mode request) by the BS. This code is applicable only when MS has a pending UL data to transmit.
- 0x04–0xFF = Reserved

The DREG-REQ message shall include the following parameter encoded as a TLV tuple if authentication is supported:

**HMAC/CMAC Tuple (see 11.1.2)**
The HMAC/CMAC Tuple shall be the last attribute in the message.

The MS shall include the following parameters in the DREG-REQ message only if the De-Registration_Request_Code parameter = 0x01:

**Paging Cycle Request**
PAGING_CYCLE requested by the MS

**Idle Mode Retain Information**
MS request for paging controller retention of network reentry-related MAC management message MS service and operational information to expedite future network reentry from idle mode. For each Bit location, a value of 0 indicates the information associated with the specified
MAC management message is not requested to be retained and managed, a value of 1 indicates the information is requested to be retained and managed.

Bit 0: Retain MS service and operational information associated with SBC-REQ/RSP messages.
Bit 1: Retain MS service and operational information associated with PKM-REQ/RSP messages.
Bit 2: Retain MS service and operational information associated with REG-REQ/RSP messages.
Bit 3: Retain MS service and operational information associated with Network Address.
Bit 4: Retain MS service and operational information associated with Time of Day.
Bit 5: Retain MS service and operational information associated with TFTP messages.
Bit 6: MS state information (see 11.14).
Bit 7: Consider Paging Preference of each service flow in resource retention. Bit 7 is meaningful when Bit 2 and Bit 6 have a value of 1. If Bit 2, Bit 6, and Bit 7 is 1, MS service and operational information associated with MS state information (see 11.14) is retained for service flows with positive Paging Preference. If Bit 2 and Bit 6 are 1 and Bit 7 is 0, MS service and operational information associated with MS State information (see 11.14) is retained for all service flows.

The MS may include the following parameters in the DREG-REQ message only if the De-registration_Request_Code parameter = 0x01:

**MAC Hash Skip Threshold**
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS individual notification for an MS, including MS MAC address hash of an MS for which the action code is 0b00 (No Action Required).

### 6.3.2.3.38 HARQ MAP message

This subclause describes the HARQ MAP message, which is designed for hybrid automatic repeat request (HARQ) enabled SS. This IE shall only be used by a BS supporting HARQ, for SS supporting HARQ.

#### 6.3.2.3.38.1 HARQ MAP message format

The HARQ MAP message format is presented in Table 110. This message includes Compact DL/UL-MAP IE and defines the access information for the DL and UL burst of HARQ-enabled SS. This message shall be sent without a generic MAC header.

BS may broadcast multiple HARQ MAP messages using multiple bursts after the MAP message. Each HARQ MAP message shall have a different modulation and coding rate.

The DL-MAP IEs in the MAP message describe the location and coding and modulation schemes of the bursts. The order of DL-MAP IEs in the MAP message and the bursts for HARQ MAP messages is determined by the coding and modulation scheme of the burst. The burst for HARQ MAP message with lower rate coding and modulation should be placed before other bursts for HARQ MAP message.

The presence of the HARQ MAP message format is indicated by the contents of the 3 MSBs of the first data byte of a burst. These bytes overlay the HT and EC bits of a generic MAC header. When these bits are both set to 1 (an invalid combination for a standard header) and followed by 1 bits of 1, the Compact DL-MAP format is present.
HARQ MAP Indicator
The value of 0b111 means this message is a HARQ MAP Message.

Compact UL-MAP appended
A value of 1 indicates a compact UL-MAP is appended to the current compact DL-MAP data structure.

MAP message length
This value specifies the length of the HARQ MAP message beginning with the byte containing the HARQ MAP indicator and ending with the last byte of the HARQ MAP message. The length includes the computed 32-bit CRC value if the CRC appended indicator is on.

DL IE count
This field holds the number of IE entries in the following list of DL-MAP IEs.

A CRC-32 value is appended to the end of the HARQ MAP data. The CRC is computed across all bytes of the HARQ MAP starting with the byte containing the HARQ MAP indicator through the last byte of the map as specified by the Map message length field. The CRC calculation is the same as that used for standard MAC messages.
Table 111 and Table 112 represent the types of Compact DL/UL-MAP IE.

<td>—</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**New Format Indication**

If this value set to 0, the format shall be configured by the latest Format Configuration IE in the previous frames. Otherwise, all parameters in Format Configuration IE shall be configured. The configured parameters are valid for the following Compact DL/UL-MAP IE. At the start of each frame, all parameters are set to default values.

**CID Type**

This value specifies CID type used in the Compact DL/UL-MAP IE.

**Safety Pattern**

If this value is less than 16, the number of safety bins is 12 and the indices of allocated bins for safety are $16m+x$, where $x$ is the value of safety pattern and $m = 0 ... 11$. If this value is from 16 to 31, the number of safety bins is 24 and the indices of allocated bins for safety are $16m+x'$ and $16m+(x'+8)$, where $x' = x - 16$ and $m = 0 ... 11$. If the safety pattern exists, it should be always allocated first. The safety pattern is valid in the region of AMC zone only. If safety pattern is set to all ones, safety channel is disabled.

**Subchannel Type for Band AMC**

This value specifies the subchannel type for band AMC subchannel. See related PHY specification.
No. Symbols for Broadcast
This field specifies the number of symbols allocated for Broadcast symbol region. The Broadcast symbols shall be allocated at the end of the DL subframe. The number of symbols is counted from the last symbol of the DL subframe. The PermBase for this broadcast symbol region shall be set to 0.

No. Symbols for DL Band AMC
This specifies the number of symbols allocated for DL band AMC symbol region. The symbols for band AMC shall be allocated before the broadcast symbol region. The other DL symbols excluding the symbols for Broadcast and DL Band are allocated for the DL Normal subchannel. PermBase for DL band AMC is the same as one for normal subchannels region.

No. Symbols for UL Band AMC
This specifies the number of symbols allocated for UL band AMC symbol region. The symbols for UL band AMC shall be allocated at the end of the UL subframe and the number of symbols are counted from the last symbol of the UL subframe. The other UL symbols excluding the symbols for UL Band are allocated for the UL Normal subchannel. PermBase for UL band AMC is the same as one for normal subchannels region.

Max Logical Bands
This value specifies the maximum number of logical bands for band AMC. The size of 3 fields (No. Selected Bands, Band BITMAP, and Band Index) in the DL/UL-MAP IE for Bands AMC depends on this value. Table 114 represents the fields in the DL/UL-MAP IE and specific values.

A logical band is a grouping of the AMC bands defined in 8.4.6.3. For example, three logical bands imply that logical band 0 is composed of AMC bands 0..15, logical band 1 is composed of AMC bands 16..31, and logical band 2 is composed of AMC bands 32..47. In general, if \( K = \text{Max Logical Bands} \), then logical band \( J = [0..(K-1)] \) contains physical bands \( 48/K \times J, 48/K \times J + 1, ..., 48/K \times (J + 1) - 1 \).

<table>

</tr>
</tbody>
</table>

### 6.3.2.3.38.3 Reduced CID
Table 115 presents the format of reduced CID. BS may use reduced CID instead of basic CID or multicast CID to reduce the size of HARQ MAP message. The type of reduced CID is determined by BS considering the range of basic CIDs of SS connected with the BS and specified by the RCI_D_Type field of the Format Configuration IE.

The reduced CID is composed of 1 bit of prefix and \( n \)-bits of LSB of CID of SS. The prefix is set to 1 for the Broadcast CID or Multicast Polling CID and set to 0 for Basic CID. The reduced CID cannot be used instead of Transport, Primary Management, or Secondary Management CID. An exception to the above is when the multicast polling RCID is used in DL. If a DL CID decoded from a prefix 1 and RCID-11 is in the range of
the Multicast Polling CID (0xFF00–0xFFFD), then the DL CID shall be interpreted as a DL Transport CID by subtracting 0xFF (0xFFFD–0xFEFE).

Figure 37 shows the decoding of reduced CID when RCID 11 is used.

Prefix = 0, Basic CID

Prefix = 1, Multicast or Broadcast

![Figure 37—Reduced CID decoding]

<td>—</td>
</tr>
<tr>
<td>RCID 3</td>
<td>3</td>
<td>3 LSBs of Basic CID</td>
</tr>
</tbody>
</table>
CID
Normal 16 bits connection identifier.

Prefix
A value of 1 indicates that 11 bits RCID for broadcast and multicast follows the prefix. Otherwise, the n-bits RCID for Basic CID follows the prefix. The value of n is determined by the RCID_Type field in Format Configuration IE.

RCID n
n-bits LSB of CID. If the DL CID decoded from a prefix 1 and RCID 11 is in the range of the Multicast Polling CID (0xFF00–0xFFFFD), then the DL CID shall be interpreted as a DL Transport CID by subtracting 0xFF (0xFFFFD–0xFEFE).

6.3.2.3.38.4 HARQ Control IE

The format of HARQ Control IE, which includes encoding/decoding information for HARQ-enabled DL/UL bursts, is presented in the MAC frame. See Table 116. This IE shall be located in the compact DL/UL-MAP IE.

</tbody>
</table>
Prefix
Indicates whether HARQ is enabled.

AI_SN
The HARQ identifier sequence number. This is toggled between 0 and 1 on successfully transmitting each encoder packet with the same ARQ channel.

SPID
The HARQ subpacket identifier, which is used to identify the four subpackets generated from an encoder packet. The SPID field only applies to FEC modes supporting incremental redundancy.

ACID
The HARQ channel identifier, which is used to identify HARQ channels. Each connection can have multiple HARQ channels, each of which may have an encoder packet transaction pending.

6.3.2.3.38.5 CQICH Control IE

The format of CQICH Control IE is presented in Table 117. The specific reporting value shall follow the directions indicated in the latest CQICH Allocation IE (8.4.5.4.11).

Table 117—CQICH Control IE format

<table>
<thead>
<tr>

</tr>
<tr>
<td>} else {</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>
### Allocation Index
Indicates its position from the start of the CQICH region.

### Period
Informs the SS of the period of CQI reports.

### Frame offset
Informs the SS of when to start. The SS starts reporting at the frame of which the number has the same 3 LSB as the specified frame offset. If the current frame is specified, the SS should start reporting in 8 frames.

### Duration
Indicates when the SS should stop reporting unless the CQICH allocation is refreshed beforehand. If duration \( d = 0b0000 \), the BS is intended to deallocate the CQICH. If \( d = 0b1111 \), the CQICH is allocated indefinitely and the SS should report until the BS commands the SS to stop, which happens it receives another MAP IE with \( d = 0b0000 \).

### CQI reporting threshold
Used by the MS to determine whether it reports current channel measurement through CQI channel if allocated in the future. See Table 118. If the value is set to \( 0b000 \), this threshold is inactive afterwards; otherwise it is activated. SS shall treat these bits as reserved and shall be set to zero.

DL-MAP Type
The DL-MAP Type value specifies the type of the Compact DL-MAP IE. A value of 0 indicates the Normal Subchannel.

UL-MAP append
A value of 1 indicates the UL access information is appended to the end of the DL-MAP IE.

RCID_IE
Represent the assignment of the IE.

$N_{EP}$ code, $N_{SCCH}$ code
The combination of $N_{EP}$ code and $N_{SCCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the DL burst.

Shortened DIUC
A shortened version of the DIUC. The shortened DIUC takes on values 0..7 of the DIUC as defined in the DCD. See 8.4.5.3.1.

Companded SC
The Companded SC indicates the number of allocated subchannels.

$N_{EP}$ code for UL, $N_{SCCH}$ code for UL
The combination of $N_{EP}$ code and $N_{SCCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the UL burst.

Shortened UIUC
A shortened version of the UIUC. The shortened UIUC takes on values 1..8 of the UIUC as defined in the UCD. See 8.4.5.4.1.

Companded SC
The Companded SC indicates the number of allocated subchannels.

6.3.2.3.38.6.2 Compact DL-MAP IE for band AMC subchannel
Slots for DL AMC zone are allocated along the subchannel index first within a band. The direction of data mapping for DL AMC zone slots shall be frequency first (across bands when multiple bands are allocated). The format of Compact DL-MAP IE for band AMC subchannel is presented in Table 120.

**DL-MAP Type**

The DL-MAP Type value specifies the type of the Compact DL-MAP IE. A value of 1 indicates the band AMC subchannel.

**RCID_IE**

Represents the assignment of the IE.
The combination of NEP code and NSCH code indicates the number of allocated subchannels and scheme of coding and modulation for the DL burst.

**Shortened DIUC**
A shortened version of the DIUC. The shortened DIUC takes on values 0..7 of the DIUC as defined in the DCD. See 8.4.5.3.1.

**Companded SC**
The Companded SC indicates the number of allocated subchannels.

**Nband**
Indicates the number of bands selected for the burst. If this value is set to 0, the Band BITMAP is used to indicate the number and the position of selected bands instead. The number of the maximum logical bands determines the length of this field.

**Band BITMAP**
The Band BITMAP is valid when Nband is 0. The \( n \)-th LSB of the Band BITMAP is set to 1 when the \( n \)-th logical band is selected for the burst. If the number of the maximum logical bands is 12, then the length of the Band BITMAP is 12 bits. The band count is set to the number of ones in the Band BITMAP. The number of the maximum logical bands determines the length of this field.

**Band Index**
The Band Index value indexes the selected band offset and is valid when Nband is larger than 0. The number of the maximum logical bands determines the length of this field.

**Allocation Mode**
The Allocation Mode value indicates the subchannel allocation mode in the selected bands. The value is set to 0 when the same numbers of subchannels are allocated in the selected bands by the No. Subchannels field. The value is set to 0b01 when different numbers of subchannels are allocated in each of the selected bands by the following No. Subchannels fields. The value is set to 0b10 when the total number of subchannels allocated in the selected bands is defined by NSCH code and NEP code. The subchannels fill from the bands with lowest index.

**No. Subchannels**
The No. Subchannels value indicates the number of subchannels allocated for this burst.

### 6.3.2.3.38.6.3 Compact DL-MAP IE for safety subchannel

</tbody>
</table>

**DL-MAP Type**

The DL-MAP Type value specifies the type of the Compact DL-MAP IE. A value of 2 indicates the safety subchannel.

**RCID_IE**

Represent the assignment of the IE.

**$N_{EP}$ code, $N_{SCCH}$ code**

The combination of $N_{EP}$ code and $N_{SCCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the DL burst.

**Shortened DIUC**

A shortened version of the DIUC. The shortened DIUC takes on values 0..7 of the DIUC as defined in the DCD. See 8.4.5.3.1.
Companded SC
The Companded SC indicates the number of allocated subchannels.

BIN Offset
The offset of the BIN allocated for this DL burst. See appropriate specification.

$N_{EP}$ code for UL, $N_{SCH}$ code for UL
The combination of $N_{EP}$ code and $N_{SCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the UL burst.

Shortened UIUC
A shortened version of the UIUC. The shortened UIUC takes on values 1..8 of the UIUC as defined in the UCD. See 8.4.5.4.1.

Companded SC
The Companded SC indicates the number of allocated subchannels.

BIN Offset for UL
The offset of the BIN allocated for this UL burst. See appropriate specification.

6.3.2.3.38.6.4 Compact DL-MAP IE for DIUC subchannel

</tbody>
</table>
6.3.2.38.6.5 Compact DL-MAP IE for HARQ ACK bitmap

The HARQ ACK bitmap information for the HARQ-enabled UL bursts is delivered through the Compact DL-MAP IE as shown in Table 123. The bit position in the bitmap is determined by the order of the HARQ-enabled UL bursts in the UL-MAP. The frame offset between the UL burst and the HARQ ACK bitmap is specified by HARQ_ACK_Delay For UL Burst field in the DCD message.

For example, when an SS transmits a HARQ-enabled burst at $i$-th frame and the burst is $j$-th HARQ-enabled burst in the MAP, the SS would receive HARQ ACK at $j$-th LSB of the bitmap, which is sent by the BS at $i+(\text{frame offset})$-th frame. If the HARQ ACK bitmap is omitted, the HARQ-enabled SS shall retain the transmitted HARQ burst and retransmit it when the BS requests retransmission with HARQ Control IE.
DL-MAP Type
Defines the type of Compact DL-MAP. If the type value is 5, the Compact DL-MAP is for HARQ-ACK-BITMAP.

BITMAP Length
Specifies the length of the following BITMAP field.

BITMAP
Includes HARQ ACK information for HARQ-enabled UL bursts. The size of BITMAP shall be equal or larger than the number of HARQ-enabled UL bursts. The {j}-th HARQ-enabled burst in the UL-MAP is corresponding to the {j}-th LSB in the BITMAP.

Whenever HARQ-enabled UL-SDMA allocations are made within a frame, the ACK BITMAP Length shall be large enough to carry the ACKs for both the SDMA and non-SDMA allocations. Also, the ACKs for the SDMA users allocated on the second layer shall be appended to the ACKs for the non-SDMA and first-layer SDMA users.

6.3.2.38.6.6 Compact DL-MAP IE for extension

The format of Compact DL-MAP IE for extension is presented in Table 124.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>

<td>Length of the IE in bytes</td>
</tr>
<tr>
<td>Payload</td>
<td>variable</td>
<td>Subtype dependent payload</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

DL-MAP Type
This value specifies the type of the Compact DL-MAP IE. A value of 7 indicates the extension type.

DL-MAP Subtype
This value specifies the subtype of the Compact DL-MAP IE.

Length
This indicates the length of this IE in bytes. If an SS cannot recognize the DL-MAP Subtype, it skips the IE.

Payload
The payload depends on the value of DL-MAP Subtype (see Table 125). The length of payload is Length – 1 bytes.

#### 6.3.2.3.38.6.7 MIMO Compact DL-MAP IE format

When MIMO-enabled DL burst are present within a frame, they shall be allocated before non-MIMO DL burst in both diversity and AMC zones. Figure 38 exemplifies the DL HARQ subframe structure, where the optional MIMO midamble is shown and 2x3 AMC type is depicted. Both MIMO diversity and MIMO AMC zones shall contain even number of symbols. For any remaining physical resources for each zone, padding subchannels shall be allocated to the region.

![Figure 38—DL HARQ subframe structure](image)

Each MIMO-enabled DL burst shall be first allocated by the regular Compact DL-MAP IE for diversity subchannels (see Table 116) and AMC subchannels (see Table 117), followed by the extended MIMO Compact DL-MAP IE. The format of MIMO Compact DL-MAP IE is presented in Table 126. This extended IE shall follow right after the basic allocation IE for each MIMO-enabled DL burst.

Matrix Indicator
This field indicates MIMO matrix for the burst.

Antenna Grouping/Selection Index
The Antenna Grouping/Selection Index field indicates antenna grouping/selection index for the current burst. For the actual description of the following matrices, see 8.4.8.3.4 and 8.4.8.3.5.

Allocation Index1
Indicates position from the start of the CQICH region.

The Feedback type of this CQICH shall be one of the three default types (type 0b000, 0b001, 0b010) according to the following rule:

Feedback type = 0b000 if ((Antenna Grouping/Selection == 1) and (matrix == A or B))
Feedback type = 0b001 if ((Antenna Grouping/Selection == 1) and (matrix == C))
Feedback type = 0b010 if ((Codebook-based precoding == 1))

Feedback Type
Indicates the type of feedback content on the allocated CQICH from MS. Its mapping shall be

0b000 = Fast DL measurement/Default Feedback with antenna grouping
0b001 = Fast DL measurement/Default Feedback with antenna selection
0b010 = Fast DL measurement/Default Feedback with reduced codebook
0b011 = Quantized precoding weight feedback
0b100 = Index to precoding matrix in codebook
0b101 = Channel Matrix Information
0b110 ~ 0b111 = Reserved

When the feedback type is either 0b000, 0b001, or 0b010, the MS shall transmit either the regular S/N measurement using the formula in 8.4.11.6 in its lower 32 codewords in 8.4.11.5 or the MIMO mode feedback of the specified type in its upper 32 codewords according to Table 524 in 8.4.11.8.

For each layer, a codeword shall be constructed according to 8.4.9.2.3.5 with the N_{EP} and N_{SCH} combination and mapped onto the corresponding layer. Multiple codewords from multiple layers shall be interpreted as one HARQ channel whose parameters are given in the preceding Compact DL-MAP IE.

At the receiver, an ACK shall be transmitted only when there is no CRC error detected on every layer. Otherwise, a NACK shall be transmitted.

SDMA transmissions may be allocated on the DL with the SDMA Compact DL-MAP IE (Table 127). Num_layer means the number of SDMA layers (2, 3, or 4) being allocated. For each SDMA layer, if the dedicated pilot bit is set to 1 in the STC Zone IE (8.4.5.3.4) for the zone in which the SDMA allocations are being made, Num_layer selects the pilot format for the burst by interpreting Num_layer as the number of Tx antennas (as defined in 8.4.8), and the MS with the first RCID shall be assigned the pilot pattern corresponding to antenna 1, of 8.4.8, the second to the pilot pattern corresponding to antenna 2, and so on.

6.3.2.3.38.6.8 HARQ Compact DL-MAP IE format for switch HARQ mode

In the HARQ-MAP, a BS may transmit DL-MAP Type = 7 with the Switch HARQ Mode IE. Allocations subsequent to this IE shall be for the HARQ mode identified. See Table 128.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

</table>

**DL-MAP Type**

The DL-MAP Type value specifies the type of the Compact DL-MAP IE. A value of 7 indicates the extension type.

**DL-MAP Subtype**

The DL-MAP Subtype value specifies the extended map type defined in Table 125 as HARQ mode switch.

**Length**

This indicates the length of this IE in bytes. This is encoded as 2.

**HARQ mode**

The HARQ mode is a 4-bit value that specifies the HARQ mode for all subsequent Compact DL-MAP IEs to the end of the current HARQ map. See 8.4.9.5 for encoding of this value.

6.3.2.3.38.6.9 HARQ Compact MBS MAP IE

The format for HARQ Compact MBS MAP IE for extension is presented in Table 129.

</tr>
</tbody>
</table>

**AI_SN**

The HARQ identifier sequence number. This is toggled between 0 and 1 on successfully transmitting each encoder packet with the same ARQ channel.

**SPID**

The HARQ subpacket identifier, which is used to identify the four subpackets generated from an encoder packet.
ACID

The HARQ channel identifier for TimeDiversity MBS packet. Each TimeDiversity MBS connection can have multiple ARQ channels, each of which may have an encoder packet transaction pending.

The MBS burst indicated by the HARQ Compact MBS MAP IE is encoded at the same way of HARQ. But it does not need the acknowledgement from MS.

6.3.2.3.38.7 Compact UL-MAP IE

6.3.2.3.38.7.1 Compact UL-MAP IE for normal subchannel

The format of Compact UL-MAP IE for normal subchannel is presented in Table 130. The direction of slot allocation and the direction of data mapping for UL shall be according to 8.4.3.4.

Table 130—HARQ Compact UL-MAP IE format for normal subchannel

<td>—</td>
</tr>
</tbody>
</table>

UL-MAP Type

The UL-MAP Type value specifies the type of the Compact UL-MAP IE. A value of 0 indicates the normal subchannel.

RCID_IE

Represent the assignment of the IE.

$N_Ep$ code, $N_{SCH}$ code

The combination of $N_Ep$ code and $N_{SCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the UL burst.
Shortened UIUC
A shortened version of the UIUC. The shortened UIUC takes on values 1..8 of the UIUC as defined in the UCD. See 8.4.5.4.1.

Companded SC
The Companded SC indicates the number of allocated subchannels.

6.3.2.3.38.7.2 Compact UL-MAP IE for band AMC subchannel

The format of Compact UL-MAP IE for band AMC subchannel is presented in Table 131. Slots for UL AMC zone are allocated along the symbol index first within a band. The direction of data mapping for UL AMC zone slots shall be frequency first (across bands when multiple bands are allocated).

Table 131—HARQ Compact UL-MAP IE format for band AMC

</tbody>
</table>

**UL-MAP Type**

The UL-MAP Type value specifies the type of the Compact UL-MAP IE. A value of 1 indicates the band AMC subchannel.

**RCID_IE**

Represents the assignment of the IE.

**$N_{EP}$ code, $N_{SCCH}$ code**

The combination of $N_{EP}$ code and $N_{SCCH}$ code indicates the number of allocated subchannels and scheme of coding and modulation for the UL burst.

**Shortened UIUC**

A shortened version of the UIUC. The shortened UIUC takes on values 1..8 of the UIUC as defined in the UCD. See 8.4.5.4.1.

**Companded SC**

The Companded SC indicates the number of allocated subchannels.

**$N_{band}$**

Indicates the number of bands selected for the burst. If this value is set to 0, the Band BITMAP is used to indicate the number and the position of selected bands instead. The number of the maximum logical bands determines the length of this field.
Band BITMAP
The Band BITMAP is valid when Nband is 0. The n-th LSB of the Band BITMAP is set to 1 when the n-th logical band is selected for the burst. If the number of the maximum logical bands is 12, then the length of the Band BITMAP is 12 bits. The band count is set to the number of ones in the Band BITMAP. The number of the maximum logical bands determines the length of this field.

Band Index
The Band Index value indexes the selected band offset and is valid when Nband is larger than 0. The number of the maximum logical bands determines the length of this field.

Allocation Mode
The Allocation Mode value indicates the subchannel allocation mode in the selected bands. The value is set to binary 00 when the same number of subchannels are allocated in the selected bands by the No. Subchannels field. The value is set to 01 when different numbers of subchannels are allocated in each selected bands by the following No. Subchannels fields. The value is set to 0b10 when the total number of subchannels allocated in the selected bands is defined by NSCH code and NEP code. The subchannels fill from the bands with lowest index.

No. Subchannels
The No. Subchannels value indicates the number of subchannels allocated for this burst.

6.3.2.3.38.7.3 Compact UL-MAP IE for safety subchannel
The format of Compact UL-MAP IE for safety subchannel is presented in Table 132.

6.3.2.3.38.7.5 Compact UL-MAP IE for HARQ region allocation

The HARQ ACK region shall reside in fast-feedback region.

The HARQ ACK region information is delivered through the Compact UL-MAP IE as shown in Table 134. SS sends ACK information for HARQ-enabled DL bursts in the HARQ region specified by the IE.

The subchannels in the HARQ ACK region are divided into two half-subchannels. The first half-subchannel is composed of first, third, and fifth tiles, and the second half-subchannel is composed of second, fourth, and sixth tiles. In the HARQ ACK region, the $2n$-th half-subchannel is the first half-subchannel and the $(2n+1)$-th half-subchannel is the second half-subchannel of the $n$-th subchannel.

The HARQ-enabled SS that receives HARQ DL burst at $i$-th frame shall transmit ACK signal through the half-subchannel in the HARQ region at $(i+j)$-th frame. The frame offset “$j$” is defined by the HARQ ACK

**UL-MAP Type**

This value specifies the type of the Compact UL-MAP IE. A value of 3 indicates the UIUC type.

**UIUC**

This value indicates the usage of this burst.

**RCID_IE**

Represents the assignment of the IE.

**No. Subchannels**

This value indicates the number of subchannels allocated by the IE.

**Repetition coding indication**

Indicates the repetition code used inside the allocated burst.

---

**Table 133—HARQ Compact UL-MAP IE format for UIUC subchannel (continued)**
Delay for DL Burst field in the UCD message. The half-subchannel offset in the HARQ Region is determined by the order of HARQ-enabled DL burst in the HARQ MAP. For example, when an SS receives a HARQ-enabled burst at $i$-th frame and the burst is $n$-th HARQ-enabled burst in the HARQ MAP, the SS would transmit HARQ ACK at $n$-th half-subchannel in HARQ region that is allocated by the BS at the $(i+j)$-th frame. The Compact MAP IE identifying the HARQ burst should set the RCID field to Basic CID of an SS, and the Prefix field in the HARQ Control IE to 1. Otherwise, the MAP IE shall not be considered as HARQ-enabled burst.

### Table 134—HARQ Compact UL-MAP IE format for HARQ region allocation

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>

</tr>
</tbody>
</table>

**UL-MAP Type**

Defines the type of Compact UL-MAP. If the type value is 4, the Compact UL-MAP is for HARQ Region allocation.

**HARQ Region Change Indication**

Indicates whether the region for HARQ ACK is changed or not.

**OFDMA Symbol offset**

**Subchannel offset**

**No. OFDMA Symbols**

**No. Subchannels**

Specify the start symbol offset, the start subchannel offset, the number of allocated symbols, and the number of subchannels for the HARQ acknowledgement region respectively.

Whenever HARQ-enabled DL-SDMA allocations are made within a frame, the ACKs for the SDMA users allocated on the second layer shall be appended to the ACKs for the non-SDMA and first-layer SDMA users.

### 6.3.2.3.38.7.6 Compact UL-MAP IE for CQICH region allocation

The HARQ CQICH region shall reside in fast-feedback region.
When there exists a need to allocate multiple CQICHs to an MS, the number of used subchannels for CQICH region shall be increased by the total number of additional CQICHs for all MSs within the frame, and their positions shall be specified by allocation indices of their respective MIMO Compact DL-MAP IE.

The CQI region information is delivered through the Compact UL-MAP IE as shown in Table 135. The SS sends CQI report in CQI region. The CQICH Control IE allocates a CQI channel in a CQICH region. When no CQICH Region Allocation IE exists in HARQ MAP, then fast-feedback region shall be used instead for CQICH region.

Table 135—HARQ Compact UL-MAP IE format for CQI region allocation

<td>—</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**UL-MAP Type**
Defines the type of Compact UL-MAP. If the type value is 5, the Compact UL-MAP is for CQI Region allocation.

**CQI Region Change Indication**
Indicates whether the region for CQI is changed or not.

**OFDMA Symbol offset**
**Subchannel offset**
**No. OFDMA Symbols**
**No. Subchannels**
Specify the start symbol offset, the start subchannel offset, the number of allocated symbols, and the number of subchannels for the CQI report region respectively.
### 6.3.2.3.38.7.7 Compact UL-MAP IE for extension

The format of Compact UL-MAP IE for extension is presented in Table 136.

#### Table 136—HARQ Compact UL-MAP IE format for extension

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>

<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**UL-MAP Type**

Specifies the type of the Compact UL-MAP IE. A value of 7 indicates the extension type.

**UL-MAP Subtype**

Specifies the subtype of the Compact UL-MAP IE.

**Length**

Indicates the length of this IE in bytes. If an SS cannot recognize the UL-MAP subtype, it skips the IE.

**Payload**

The payload depends on the value of UL-MAP subtype. The length of payload is Length – 1 bytes.

Table 137 represents the extended types of compact UL MAP.

#### Table 137—UL-MAP subtypes

<table>
<thead>

</tr>
<tr>
<td>Start subchannel offset</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**UL-MAP Type**

Specifies the type of the Compact UL-MAP IE. A value of 7 indicates the extension type.

**UL-MAP Subtype**

Specifies the subtype of the Compact UL-MAP IE.

**Length**

Indicates the length of this IE in bytes. If an SS cannot recognize the UL-MAP subtype, it skips the IE.

**Start symbol offset**

A subsequent HARQ UL data burst allocation shall start from the symbol specified in the value. However, this value does not affect to the ranging region, CQICH region, and HARQ ACK region.

**Start subchannel offset**

A subsequent HARQ UL data burst allocation shall start from the subchannel specified in the value. However, this value does not affect to the ranging region, CQICH region, and HARQ ACK region.

6.3.2.3.38.7.9 MIMO Compact UL-MAP IE format

When MIMO-enabled UL burst are present within a frame, they shall be allocated before non-MIMO DL burst in both diversity and AMC zones. Figure 38 exemplifies the UL HARQ subframe structure, where the 1-by-6 AMC type is depicted.

Within the MIMO diversity zone, subchannels shall take the form of Mini-subchannel Type 0b01 in Table 389, which spans over six symbols. Within the MIMO AMC zone, subchannels shall take 1-by-6 AMC type. Both MIMO diversity and MIMO AMC zones shall contain multiples of six symbols.

Each MIMO-enabled UL burst shall be first allocated by the regular Compact UL-MAP IE for diversity subchannels (see Table 123) and AMC subchannels (see Table 124), followed by the extended MIMO
Compact UL-MAP IE. The indication of zone boundary shall be made by the presence of UL Zone IE in Table 388.

The format of MIMO Compact UL-MAP IE is presented in Table 139. This extended IE shall follow right after the basic allocation IE for each MIMO-enabled UL burst.

### Table 139—MIMO Compact UL-MAP IE format

</tbody>
</table>

For each layer, a codeword shall be constructed according to 8.4.9.2.3.5 with the $N_{EP}$ and $N_{SCH}$ combination and mapped onto the corresponding layer. Multiple codewords from multiple layers shall be interpreted as one HARQ channel whose parameters are given in the preceding Compact UL-MAP IE.
At the receiver, an ACK shall be transmitted only when there is no CRC error detected on every layer. Otherwise, a NACK shall be transmitted.

6.3.2.3.38.7.10 SDMA Compact UL-MAP IE format

SDMA transmissions may be allocated in the UL with the SDMA Compact UL-MAP IE (Table 140).

<table>
<thead>

**Num_layer**

The Num_layer specifies the number of SDMA layers. It is interpreted as the number of Tx antennas (as defined in 8.4.8). The first layer/user shall use pilot pattern A and the second layer/user shall use pilot pattern B. The third layer/user shall use pilot pattern C and the fourth layer/user shall use pilot pattern D.
6.3.2.3.39 MOB_SLP-REQ (sleep request) message

An MS supporting sleep mode uses the MOB_SLP-REQ message to request definition and/or activation of certain Power Save Classes of types 1, 2, and 3. The MOB_SLP-REQ message is sent from the MS to the BS on the MS’s Basic CID. If Definition bit is set, the message contains suggested by the MS definition of new power saving class. See Table 141.

Parameters shall be as follows:

**Definition**
0 = Definition of power saving class absent; in this case the message shall request activation or deactivation of power saving class identified by Power_Saving_Class_ID.

1 = Definition of power saving class present.

**Operation**
0 = Deactivation of power saving class (for types 1 and 2 only).

1 = Activation of power saving class.

If Definition == 1 and Operation == 0
Then MOB_SLP-RSP contains definition of new Power Saving Class without immediate activation.

If Definition == 1 and Operation == 1
Then MOB_SLP-RSP contains definition of Power Saving Class and activates the Power Saving Class per the parameters in the message

If Definition == 0 and Operation == 0
Then MOB_SLP-RSP deactivates the previously defined active Power Saving Class

If Definition == 0 and Operation == 1
Then MOB_SLP-RSP activates the previously defined Power Saving Class

**Power Saving Class Type**
0b01 = power saving class type I

0b10 = power saving class type II

0b11 = power saving class type III

**Power_Saving_Class_ID**
Assigned power saving class identifier. The ID shall be unique within the group of power saving classes associated with the MS. This ID may be used in further MOB_SLP-REQ/RSP messages for activation/deactivation of power saving class.

**Start_frame_number**
Start frame number for first sleep window.
**Direction**

Defined the directions of the class’s CIDs.

- 0b00 = Unspecified. Each CID has its own direction assign in its connection creation. Can be DL, UL, or both.
- 0b01 = DL direction only.
- 0b10 = UL direction only.
- 0b11 = Reserved.

**TRF-IND_Required**

For Power Saving Class Type I only.

1 = BS is requested to transmit at least one MOB_TRF-IND message. The BS shall transmit at least one MOB_TRF-IND message in each availability interval which contains at least one listening window for Power Saving Class of type I.

This bit shall be set to 0 for other types.

**Traffic_triggered_wakening_flag (for Type I only)**

- 0 = Power saving class shall not be deactivated if traffic appears at the connection as described in 6.3.20.2.
- 1 = Power saving class shall be deactivated if traffic appears at the connection as described in 6.3.20.2.

**Listening window**

Assigned Duration of MS listening window (measured in frames). For power saving class type III, it is not relevant and shall be encoded as 0.

**Initial-sleep window**

Assigned initial duration for the sleep window (measured in frames). For power saving class type III, it is not relevant and shall be encoded as 0.

**Final-sleep window base**

Assigned final value for the sleep interval (measured in frames). For power saving class type II, it is not relevant and shall be encoded as 0. For power saving class type III, it is the base for duration of single sleep window requested by the message.

**Final-sleep window exponent**

Assigned factor by which the final-sleep window base is multiplied in order to calculate the final-sleep window. The following formula is used:

\[
\text{final-sleep window} = \text{final-sleep window base} \times 2^{(\text{final-sleep window exponent})}
\]

For power saving class type III, it is the exponent for the duration of single sleep window requested by the message.

**Number_of_CIDs**

Number_of_CIDs = 0 means all CIDs associated with the MS at the time the MOB_SLP-REQ message is transmitted are added to the Power Saving Class.

**CID**

CIDs of all connections comprising the Power Saving Class. If Basic CID is included, it means that all MS management connections are included in the Power Saving Class. If CID=0 is included, that means all current transport connections at the time the MOB_SLP-REQ message is transmitted are added to the Power Saving Class.
The following TLV parameter may be included in MOB_SLP-REQ message transmitted when requesting an activation of power saving class. This TLV indicates the enabled action that MS performs upon reaching trigger condition in sleep mode.

**Enabled-Action-Triggered**
Indicates possible action upon reaching trigger condition.

The following TLV parameter may be included in MOB_SLP-REQ message transmitted when requesting an activation of power saving class. This TLV indicates that the unavailability interval of the activated PSC is to be used for coexistence purposes in the MS and the BS is requested to use coexistence behavior for the PSC.

**Co-located-Coexistence-Enabled**
This TLV indicates the PSC is also to support co-located coexistence.

The following TLV may be included in the MOB_SLP-REQ message:

**Sleep mode functions enabled in H-FDD**
This TLV indicates features that are to be used to support H-FDD operation.

The MOB_SLP-REQ shall include the following parameters encoded as TLV tuples:

**HMAC/CMAC Tuple (see 11.1.2)**
The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.40 MOB_SLP-RSP (sleep response) message

The MOB_SLP-RSP message shall be sent from BS to an MS on Broadcast CID (PSC type III only) or on the MSs basic CID in response to a MOB_SLP-REQ message. The BS may end the unsolicited MOB_SLP-RSP message for the purpose of activation or deactivation only. The BS may either reconfigure sleep mode parameters in MOB_SLP-RSP by using the same Power Saving Class ID, or may define a new sleep class by using a new Power Saving Class ID. When defining a new sleep class: the Definition bit shall be set, and the message shall contain the definition of a new Power Saving Class together with an assigned Power_Saving_Class_ID that shall be unique per MS if unicast traffic connections are included and unique per cell if only multicast connections are included.

In case the MS receives a MOB_SLP-RSP message with Definition=1 and Operation=1 regarding a Power Saving Class that is currently activated, then the MS shall deactivate the Power Saving Class and re-activate it according to the new definition.

After reception of the message, the MS shall assemble connections in power saving classes and optionally activate them as requested in the message. If for certain class activation is deferred (Activation = 0), the BS may signal activation at later time in another unsolicited MOB_SLP-RSP message (Table 142).

</tr>
</tbody>
</table>

If MDHO or FBSS capability is enabled in the REG-REQ/RSP message exchange.
Parameters shall be as follows:

**Length of Data**
Number of bytes in following specification of power saving class, including all fields within the FOR loop.

**Sleep Approved**
- 1 = Indicates that BS approves the MS’s Definition/Activation/Deactivation Request of the power saving class.
- 0 = Indicates that BS disapproves the MS’s Definition/Activation/Deactivation Request of the power saving class.

For a MOB_SLP-RSP message transmitted in an unsolicited manner, the BS shall set 'Sleep approved' = 1 and 'Definition' = 0 for each Power Saving Class.

**Definition**
- 0 = Definition of Power Saving Class absent
- 1 = Definition of power saving class present.

**Operation**
- 0 = Deactivation of power saving class (for types I and II only).
- 1 = Activation of power saving class.

If Definition == 1 and Operation == 0
Then MOB_SLP-RSP contains definition of new Power Saving Class without immediate activation.
If Definition == 1 and Operation == 1
Then MOB_SLP-RSP contains definition of Power Saving Class and activates the Power Saving Class per the parameters in the message
If Definition == 0 and Operation == 0
Then MOB_SLP-RSP deactivates the previously defined active Power Saving Class
If Definition == 0 and Operation == 1
Then MOB_SLP-RSP activates the previously defined Power Saving Class
**Power_Saving_Class_ID**
Assigned power saving class identifier. The ID shall be unique within the group of power saving classes associated with the MS. This ID may be used in further MOB_SLP-REQ/RSP messages for activation/deactivation of power saving class.

**Start_frame_number**
Start frame number for first sleep window.

**REQ-duration**
Waiting value for the MOB_SLP-REQ message retransmission (measured in MAC frames): the MS may retransmit the MOB_SLP-REQ message after the time duration (REQ-duration) provided in the message.

**Power_Saving_Class_Type**
0b01 = power saving class type I
0b10 = power saving class type II
0b11 = power saving class type III

**Stop_CQI_Allocation_Flag**
1 = Indicates that this MOB_SLP-RSP message deallocates all CQICH allocated to the MS.
0 = Indicates that this MOB_SLP-RSP message does not deallocate any CQICH allocated to the MS, and the MS shall continue to transmit channel quality information on the CQICH during its availability intervals.

**Direction**
Defined the directions of the class’s CID:

- 0b00 = Unspecified. Each CID has its own direction assigned in its connection creation. Can be DL, UL, or both.
- 0b01 = DL direction (for management connections only).
- 0b10 = UL direction only.
- 0b11 = Reserved.

**Listening interval**
Assigned Duration of MS listening interval (measured in frames). For power saving class type III, it is not relevant and shall be encoded as 0.

**Initial-sleep window**
Assigned initial duration for the sleep window (measured in frames). For power saving class type III, it is not relevant and shall be encoded as 0.

**Final-sleep window base**
Assigned final value for the sleep interval (measured in frames). For power saving class type II, it is not relevant and shall be encoded as 0. For power saving class type III, it is the base for duration of single sleep window requested by the message.

**Final-sleep window exponent**
Assigned factor by which the final-sleep window base is multiplied in order to calculate the final-sleep window. The following formula is used:

\[
\text{final-sleep window} = \text{final-sleep window base} \times 2^{(\text{final-sleep window exponent})}
\]

For power saving class type III it is the exponent for the duration of single sleep window requested by the message.
TRF-IND_Required
For power saving class type I only.

1 = The BS shall transmit at least one MOB_TRF-IND message in each availability interval which contains at least one listening window of Power Saving Class of type I.
This bit shall be set to 0 for another types.

Traffic_triggered_wakening_flag (for Type I only)
1 = Power saving class shall be deactivated if traffic appears at the connection as described in 6.3.20.2.
0 = Power saving class shall not be deactivated if traffic appears at the connection as described in 6.3.20.2.

SLPID
This is a number assigned by the BS whenever an MS is instructed to enter sleep mode. This number shall be unique in the sense that it is assigned to a single MS that is instructed to enter sleep mode. No other MS shall be assigned the same number while the first MS is still in sleep mode.

Number_of_CIDs
Number_of_CIDs = 0 means all CIDs associated with the MS at the time the MOB_SLP-RSP message is received are added to the Power Saving Class.

CID
CIDs of all connections comprising the Power Saving Class. If Basic CID is included, it means that all MS management connections are included in the Power Saving Class. If CID = 0 is included, that means all current transport connections are added to the Power Saving Class. If Definition = 1, then the service flow management encoding PSC Assignment shall be set to the value of the Power_Saving_Class_ID in this message corresponding to the transport connection identified in the CID information element.

Maintain Diversity Set and Anchor BS
1: The Diversity set and anchor BS shall be maintained while in sleep mode for MDHO/FBSS duration.
0: The Diversity set and anchor BS shall not be maintained while in sleep mode.

MDHO/FBSS duration(s)
The Diversity set and anchor BS shall be maintained for 10x2exp(s) frames after the power saving class is activated.

The following TLV parameter may be included in the MOB_SLP-RSP message transmitted by the BS.

Enabled-Action-Triggered (11.1.7.1)
This TLV indicates the enabled action that the MS performs upon reaching trigger condition in sleep mode.

Next Periodic Ranging (11.1.7.3)
This value indicates the offset of frame in which MS shall be ready to perform a periodic ranging with respect to the frame where MOB_SLP-RSP is transmitted.

Sleep mode functions enabled in H-FDD
This TLV indicates features that are to be used to support H-FDD operation.

The MOB_SLP-RSP shall include the following parameter encoded as TLV tuples:
HMAC/CMAC Tuple (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

The BS shall not use Number_of_CIDs=0 or CID=0 during a transaction of DSA or DSD at the BS where the CIDs defined may be different between MS and BS. The start and end of this conditional restriction are respectively defined by the following:

— The sending of the request, and the reception of the response for a BS initiated transaction.
— The reception of the request, and the reception of the acknowledgement for a MS initiated transaction.

When a MS has sent a MOB_SLP-REQ message including a definition, it shall not initiate a DSA or DSD transaction until it has received a MOB_SLP-RSP.

6.3.2.3.41 MOB_TRF-IND (traffic indication) message

This message is sent from the BS to the MS on the Broadcast CID or Sleep Mode Multicast CID. The message is intended for MSs in sleep mode that have one or more power saving class IDs defined with power saving class type I, and is sent during those MS’s listening-intervals. All MSs with no power saving class IDs defined of power saving class type I shall ignore this message. The message indicates whether there has been traffic addressed to each MS that is in sleep mode. For an MS that is in sleep mode, during its listening-window the MS shall decode this message to seek an indication addressed to itself.

When an MS awakens, it shall check the frame number to ensure that it did not lose frame synchronization with the BS and read the SLPID-Group Indication bit-map or Traffic Indication bit-map assigned to it. If the MOB_TRF-IND has a positive indication, this message indicates that there is traffic directed to the MS and the MS shall deactivate the power saving class.

If the MOB_TRF-IND has a negative indication, this message indicates that there is no current traffic pending for CIDs belonging to this PSC. The MS continues to receive all DL transmission including subsequent MOB_TRF-IND messages in the availability interval.

There are two formats for the MOB_TRF-IND message, indicated by the FMT field. When FMT = 0, if the MS does not find its own SLPID-Group Indication bit-map or Traffic Indication bit-map to its SLPID in the MOB_TRF-IND message, it shall consider this as a negative indication and may continue its sleep mode. The MS shall update its SLPID if it finds its own Old_New_SLPID in SLPID_Update TLV (11.1.7.2). When FMT = 1, if the MS does not find its own SLPID in the MOB_TRF-IND message, it will consider this as a negative indication and may continue its sleep mode.

BS may arbitrarily include a positive indication for an MS in MOB_TRF-IND message during listening-window if the MS’s periodic ranging operation is scheduled to start sooner or later within next sleep-window, even if there is no DL Traffic to be sent to the MS. See Table 143.
Parameters shall be as follows:

**FMT**

The FMT field indicates one of the SLPID bit-map based format and the SLPID based format.

### Table 143—MOB_TRF-IND message format

|     | **Num_Pos**                                | 8          | Number of SLPIDs following                                           |
|     | for (i = 0; i < Num_Pos; i++) {            | —          | —                                                                     |
|     |     **SLPID**                               | 10         | —                                                                     |
|     | }                                           | —          | —                                                                     |
| }                                            | —          | —                                                                     |
| **Padding**                                 | variable   | If needed, for alignment to byte boundary.                           |
| **TLV encoded items**                       | variable   | —                                                                     |
| }                                            | —          | —                                                                     |
SLPID-Group Indication Bitmap

SLPIDs from 0 to 1023 are divided into 32 SLPID-Groups. Therefore, the respective SLPID-Group has the range as follows:

- SLPID-Group #0 (MSB) corresponds to SLPID = 0…31.
- SLPID-Group #1 corresponds to SLPID = 32…63.

... 

- SLPID-Group #31 corresponds to SLPID = 992…1023.

SLPID-Group Indication Bitmap is a 32-bit field where each bit is assigned to the respective SLPID-Group. In other words, the MSB in the field is assigned to SLPID-Group #0, and subsequent bit relates to SLPID-Group #1, etc.

The $n$-th bit ($b_n$, $n = 0$–31) of SLPID-Group Indication Bitmap shall be interpreted in the following manner:

- $b_n = 0$ means that there is no traffic for all the 32 MS belonging to SLPID-Group #$n$. In this case, the MS in sleep mode belonging to SLPID-Group #$n$ may return to sleep mode.
- $b_n = 1$ means that there exists traffic for one or more MS belonging to SLPID-Group #$n$. In this case, the MS in sleep mode belonging to SLPID-Group #$n$ shall read its own Traffic Indication bit-map in MOB_TRF-IND message.

Traffic Indication bit-map

The Traffic Indication bit-map comprises the multiples of 32-bit long Traffic Indication Unit for every SLPID-Group with SLPID-Group indication bit = 1. Bits in a 32-bit Traffic Indication unit (starting from MSB) are allocated to MS to in ascending order of SLPIDs. Each bit signals traffic information for the corresponding MS as follows:

- 0: Negative indication
- 1: Positive indication

Num-pos

The number of positive indication.

SLPID

The SLPID for the Power_Saving_Class_ID deactivated by this message and for MS to be transited into an awake mode.

When MOB_TRF-IND message has FMT = 0, it may include the following TLV:

SLPID_Update (11.1.7.2)

The SLPID_Update is a compound TLV value that provides a shorthand method for changing the SLPID used by the MS in sleep mode operation. The SLPID_Update TLV specifies a new SLPID that replaces an old SLPID. The SLPID_Update TLV may contain multiple Old_New_SLPID values for the MS negatively indicated in MOB_TRF-IND message.

6.3.2.3.42 MOB_NBR-ADV (neighbor advertisement) message

BSs supporting mobile functionality shall be capable of transmitting a MOB_NBR-ADV management message at a periodic interval (MOB_NBR-ADV interval; see Table 554) to identify the network and define the characteristics of neighbor BS to potential MS seeking initial network entry or HO. For the compression of neighbor BSIDs using this message in MOB_SCN-REQ, MOB_SCN-RSP, MOB_SCN-REP, and MOB_MSHO-REQ messages, the BS shall keep a mapping-table of neighbor BS MAC addresses and neighbor BS indexes transmitted through MOB_NBR-ADV message, for each Configuration Change Count. Using these mapping-tables, BSs can derive 48-bit neighbor BSID from neighbor BS index included...
in MOB_SCN-REQ, MOB_SCNRSP, MOB_SCN-REP or MOB_MSHO-REQ messages. MOB_SCN-REQ, MOB_SCN-RSP, and MOB_SCN-REP messages may identify the MOB_NBR-ADV BS indexes using a BS index bitmap (Nbr_Index_Bitmap), where a BS index corresponds to the position of a BS in the MOB_NBR-ADV message and a bit position in the bitmap corresponds to a BS index of the MOB_NBR-ADV.

If neighbor information is not available, this message need not be transmitted. See Table 144.

</tbody>
</table>
A BS shall generate MOB_NBR-ADV messages in the format shown in Table 144. The following parameters shall be included in the MOB_NBR-ADV message unless otherwise noted as an optional item in which case they may be included:

**Reuse factor for SBS CINR calculation for scan and handover**

- **0b00:** Physical SBS CINR for scan or handover triggers shall be calculated according to the number of subcarriers indicated in the DL Frame Prefix “Used subchannel bitmap” field. If the number of used subcarriers is lower than or equal to one third of the total number of subcarriers, then CINR shall be computed according to the rule detailed in 8.4.12.3 for frequency reuse configuration = 3. Otherwise the CINR shall be computed according to the rule detailed in 8.4.12.3 for frequency reuse configuration = 1.

- **0b10:** Physical SBS CINR for scan or handover triggers shall be calculated according to the rule detailed in 8.4.12.3 for frequency reuse configuration = 1.

- **0b01:** Physical SBS CINR for scan or handover triggers shall be calculated according to the rule detailed in 8.4.12.3 for frequency reuse configuration = 3.

- **0b11:** Reserved

**Operator ID**

The network ID shared by an association of BS. The Operator ID field is present only if Bit 0 of Skip-optional-fields bitmap is set to 0. The most significant 24 bits of the Base Station ID shall be used as the Operator ID. The 24-bit Operator ID shall be assigned as an IEEE 802.16 Operator ID by the IEEE Registration Authority.\(^\text{14}\) The IEEE Registration Authority shall be the sole authorized number space administrator for this function.

---

\(^{14}\)The IEEE Registration Authority is a committee of the IEEE Standards Association Board of Governors. General information as well as details on the allocation of IEEE 802.16 Operator ID can be obtained at http://standards.ieee.org/regauth.
Configuration Change Count
Incremented by one (modulo 256) whenever any of the values relating to any included data element changes, including DCD and UCD parameters. If the value of this count in a subsequent MOB_NBR-ADV message remains the same, the MS can quickly disregard the entire message.

Fragmentation Index
The Fragmentation Index field indicates the current fragmentation index. The index for the first fragmentation is 0.

Total Fragmentation
The Total Fragmentation field set to 1 when the neighbor list is not fragmented. Otherwise, this field indicates the total number of fragments. When the neighbor list is fragmented, the N_NEIGHBORS indicates the number of neighbor BSs in the current message.

Skip-optional-fields Flag:
The Skip-optional-fields Flag indicates whether some fields in MOB_NBR-ADV message may be omitted in the MOB_NBR-ADV message. The field is omitted if the bit is set to 1.

- Bit 0: Omit Operator ID field
- Bit 1: Omit NBR BSID field
- Bit 2: Omit HO process optimization field
- Bit 3: Omit QoS related fields

N_NEIGHBORS
The count of the unique combination of neighbor BSID, preamble index, and DCD.

For each advertised neighbor, the following parameters shall be included:

Length
Length of message information within the iteration of N_NEIGHBOR in bytes.

Neighbor BSID
The 24 LSBs of the Base Station ID parameter in the DL-MAP message of the neighbor BS. The Neighbor BSID field is present only if Bit 1 of Skip-optional-fields bitmap is 0.

Preamble Index/Subchannel Index
For the OFDMA PHY this parameter defines the PHY-specific preamble. For the OFDM PHY the 5 LSB contain the DL subchannel index (as defined in Table 248) used in the advertised BS sector. The 3 MSB shall be reserved and set to 0b000.

PHY Profile ID
The PHY Profile ID contains a subset of the MOB_NBR-ADV message fields. For systems using OFDM or OFDMA, the bit-by-bit definition of the PHY Profile ID is shown in Table 145.
### Table 145—Bit-by-bit definition of PHY Profile ID of the BS

<table>

<tbody>
<tr>
<td>Co-located FA Indicator</td>
<td>1</td>
<td>If the BS (or FA) is co-located with the serving BS, this bit is set to 1. If this bit is set to 1, the following fields of the MOB_NBR-ADV TLV may be omitted: Preamble Index, HO Process Optimization, DCD/UCD Configuration Change Count, and TLV Encoded Neighbor Information</td>
</tr>
<tr>
<td>FA Configuration Indicator</td>
<td>1</td>
<td>If this bit is set 1, the BS has the same FA configuration (the same number of FAs as well as their frequencies) as the BS broadcasting the NBR-ADV.</td>
</tr>
</tbody>
</table>
| Time/Frequency Synchronization Indicator | 2          | 0b00 = Unsynchronized  
0b01 = Time synchronization  
0b10 = Time and Frequency synchronization  
If time synchronization is indicated for the OFDMA PHY, then the DL frames transmitted by the serving BS and the neighbor BS shall be synchronized to a level of at least 1/8 cyclic prefix length.  
If frequency synchronization is indicated for the OFDMA PHY, then the BS reference clocks shall be synchronized to a level that yields RF center frequency offset of no more than 1% of the OFDMA carrier spacing of the neighbor BS. |
| BS EIRP Indicator             | 1          | If this bit is set, the BS EIRP follows the PHY Profile ID.                                                                 |
| DCD/UCD Reference Indicator   | 1          | 1: The DCD/UCD settings of this neighbor BS are the same as those of the preceding neighbor BS unless the TLV information specifies.  
0: The DCD/UCD settings of this neighbor BS are the same as those of the serving BS unless the TLV information specifies. |
| FA Index Indicator            | 1          | Only if this bit is set to 1, the FA Index follows the PHY Profile ID. In addition, if the FA Indicator is followed, the DL center frequency shall be omitted in the DCD/UCD difference TLV information. |
| Trigger Reference Indicator   | 1          | The Trigger Reference Indicator is related to the neighbor BS trigger metric TLV information of this neighbor BS.  
0: In addition to triggers defined by Neighbor BS Trigger TLVs, the MS shall apply the triggers for actions 0x1 and 0x2 defined the DCD message that do not have the same type, function and action as a trigger defined in a Neighbor BS Trigger TLV.  
1: In addition to triggers defined by Neighbor BS Trigger TLVs, the MS shall apply the triggers for action of the preceding neighbor BS that do not have the same type, function and action as a trigger defined in a Neighbor BS Trigger TLV. |

**FA Index**

Only if the FA Index Indicator bit in the PHY Profile ID is set to 1, the FA Index follows the PHY Profile ID. In addition, if the FA Indicator is followed, the DL center frequency shall be omitted in the DCD/UCD difference TLV information. The bit-by-bit definition shall be determined by a service provider or a governmental body like FCC.

**BS EIRP**

The neighbor BS EIRP is listed in a signed integer form from –128 to 127 in units of dBm. The BS EIRP field shall be omitted if the BS EIRP Indicator bit in PHY Profile ID is set zero.
**HO Process Optimization**

HO Process Optimization is provided as part of this message is indicative only. HO process requirements may change at time of actual HO. For each Bit location, a value of 0 indicates the associated reentry management messages shall be required, a value of 1 indicates the reentry management message may be omitted. Regardless of the HO Process Optimization TLV settings, the target BS may send unsolicited SBC-RSP and/or REG-RSP management messages:

- Bit 0: Omit SBC-REQ/RSP management messages during reentry processing
- Bit 1: Omit PKM Authentication phase except TEK phase during current reentry processing
- Bit 2: Omit PKM TEK creation phase during reentry processing
- Bit 3: Omit Network Address Acquisition management messages during current reentry processing
- Bit 4: Omit Time of Day Acquisition management messages during current reentry processing
- Bit 5: Omit TFTP management messages during current re-entry processing
- Bit 6: Full service and operational state transfer or sharing between serving BS and target BS (All static and dynamic context, e.g., ARQ window contents, timers, counters, state machines)
- Bit 7: Omit REG-REQ/RSP management during current re-entry processing

**Scheduling Service Supported**

The Scheduling Service Supported field is present only if Bit 3 of Skip-optional-fields is 0. Bitmap to indicate if BS supports a particular scheduling service. 1 indicates support, 0 indicates not support:

- Bit 0: UGS
- Bit 1: rtPS
- Bit 2: nrtPS
- Bit 3: BE
- Bit 4: ertPS

If the value of Bit 0 through Bit 4 is 0b00000, it indicates no information on service available.

**DCD Configuration Change Count**

Represents the 4 LSBs of the neighbor BS current DCD configuration change count.

**UCD Configuration Change Count**

Represents the 4 LSBs of the neighbor BS current UCD configuration change count.

For each advertised neighbor BS, the following TLV parameters may be included:

**Mobility Feature Supported**

Same as in 11.7.13.1.

The following TLV parameters may be included:

**DCD_settings**

The DCD_settings is a compound TLV that encapsulates TLVs from the neighbor BS’s DCD message that may be transmitted in the advertised BS downlink channel. This information is intended to enable fast synchronization of the MS with the advertised BS downlink. The DCD settings fields shall contain only neighbor’s DCD TLV values that are different from the serving BS corresponding values or from the DCD_settings of the previous neighbor BS,
whichever is referenced by the DCD/UCD Reference Indicator in the PHY Profile ID. Neighbor BS TLVs that are already represented within the fixed fields of the MOB_NBR-ADV message (e.g., BS_EIRP, DCD configuration change count, neighbor BSID) shall be excluded. For values that are not included, the MS shall assume they are identical to the corresponding values of the serving BS. The duplicate TLV encoding parameters within a Neighbor BS shall not be included in DCD setting.

If the set of paging groups with which the neighbor BS is affiliated is different from the set of paging groups with which the Serving BS is affiliated, the Paging Group ID TLV, containing all the paging groups with which the neighbor BS is affiliated, shall be included.

**UCD_settings**

The UCD_settings is a compound TLV that encapsulates TLVs from the neighbor BS’s UCD message that may be transmitted in the advertised BS downlink channel. This information is intended to enable fast synchronization of the MS with the advertised BS uplink. The UCD settings fields shall contain only neighbor’s UCD TLV values that are different from the serving BS’s corresponding values or from the UCD_settings of the previous neighbor BS, whichever is referenced by the DCD/UCD Reference Indicator in the PHY Profile ID. Neighbor BS UCD TLVs that are already represented within the fixed fields of the MOB_NBR-ADV message (e.g., UCD configuration change count) shall be excluded. For values that are not included, the MS shall assume they are identical to the serving BS’s corresponding values. The duplicate TLV encoding within a Neighbor BS shall not be included in UCD setting.

NOTE—The fixed fields of the neighbor BS’s UCD message may be represented by UCD TLVs 198 through 201.

The MOB_NBR-ADV message shall include the BSID of advertised neighbors, either using the Operator ID and the Neighbor BSID fields, or as part of an included DCD_settings TLV.

When the PHY parameters specified by the PHY Mode ID TLV are different than those of the serving BS, the following TLV shall be included:

**Neighbor BS Trigger**

See 11.18.1.

**PHY Mode ID** (see 11.18.2)

A 16-bit value that specifies the PHY parameters, including channel bandwidth, FFT size, cyclic prefix, and frame duration.

**MCID_Preallocation and Transmission Info** (see 11.1.12.1)

MCID_Preallocation and Transmission Info is used by the BS’s in one MBS-Zone to provide information about changes in mapping of current MCIDs in the select other MBS Zones as determined by the serving MBS Zone.

**MCID-Continuity and Transmission Info** (see 11.1.12.2)

MCID-Continuity and Transmission Info is used by the BS’s in one MBS-Zone to show consistency of MCID’s mapping used in select other MBS Zones as determined by the serving MBS Zone.
6.3.2.3.43 MOB_SCN-REQ (scanning interval allocation request) message

A MOB_SCN-REQ message may be transmitted by an MS to request a scanning interval for the purpose of seeking available BSs and determining their suitability as targets for HO. An MS may request the scanning allocation to perform scanning or noncontention association ranging.

For the compression of neighbor BSIDs through a reference to this message in MOB_SCN-RSP, the BS may keep a mapping-table of neighbor BS MAC addresses and neighbor BS indexes transmitted through this message, for each MOB_SCN-REQ sequence number (Req_Seq_Num), where a BS index corresponds to the position of a BS in the MOB_SCN-REQ message, such that a BS Index of 0 identifies the first BS in the MOB_SCN-REQ message and each next BS Index (incremented by 1) identifies the next BS in the message, according to the sequential order that the BSs appear in the message.

A BS index bitmap (Req_Bitmap_Index) in a MOB_SCN-RSP message may be used to identify MOB_SCN-REQ BS indexes such that each bit position corresponds to a BS Index of the corresponding MOB_SCN_REQ message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last requested BS, and BSs with BS Index greater than the last requested BS are not requested and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is requested and a bit value of 0 indicates that the BS is not requested.

An MS shall generate MOB_SCN-REQ messages in the format shown in Table 146.

</tbody>
</table>
The following parameters shall be included in the MOB_SCN-REQ message:

**Scan duration**
Duration (in units of frames) of the requested scanning period.

**Interleaving Interval**
The period of MS’s normal operation that is interleaved between Scanning Durations.

**Scan Iteration**
The requested number of iterating scanning interval by an MS.

**N_Recommended_BS_Index**
If not equal to 0xFF, this is the number of neighboring BS to be scanned or associated, which are included in MOB_NBR-ADV message. If equal to 0xFF, this indicates that the BS index bitmap (Nbr_Bitmap_Index) is used to identify the BS index that corresponds to the position of BS in MOB_NBR-ADV message. When MS receives MOB_SCN-RSP message from BS in response to MOB_SCN-REQ message, MS shall check whether Configuration Change Count stored by MS is the same as one included in MOB_SCN-RSP message sent by BS. If MS detects mismatch of Configuration Change Counts, it may retransmit MOB_SCN-REQ message to BS. In this case, MS shall set this value to zero.

**Configuration Change Count for MOB_NBR-ADV**
The value of Configuration Change Count in MOB_NBR-ADV message referred in order to compress neighbor BSID.

---

</tr>
</tbody>
</table>
Req_Seq_Num
One-bit sequence number for the MOB_SCN-REQ message that is toggled for each new message and may be included in a MOB_SCN-RSP message to identify the MOB_SCNREQ message associated with a MOB_SCN-REQ BS Index bitmap (Req_Bitmap_Index), where a bit position in this bitmap corresponds to a BS index of the MOB_SCN-REQ message and where a BS index corresponds to the position of a BS in the MOB_SCN-REQ message. When an MS receives a MOB_SCN-RSP message from the BS that includes Req_Seq_Num, the MS shall compare its stored value of Req_Seq_Num with the one included in the MOB_SCN-RSP message and discard the MOB_SCN-RSP message if there is a mismatch.

Nbr_Bitmap_Index
Bitmap of BS indexes for a MOB_NBR-ADV message, where each bit position corresponds to a BS Index of the corresponding MOB_NBR-ADV message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last requested BS, and BSs with BS Index greater than the last requested BS are not requested and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is requested and a bit value of 0 indicates that the BS is not requested.

Neighbor_BS_Index
BS index corresponds to position of BS in MOB_NBR-ADV message.

Scanning type
Type of scanning or association to be used by the MS and coordinated by the serving BS (if Association type ≥ 0b011).

N_Recommended_BS_Full
Number of neighboring BS to be scanned or associated, which are using full 48-bit BSID.

Recommended BSID
Identifiers of the BSs the MS plans to scan with or without association.

The MOB_SCN-REQ message may include the following parameters encoded as TLVs:

Sleep Mode Reactivation Information (see 11.20.2)
Recommended start frame (see 11.20)

The MOB_SCN-REQ message shall include the following parameters encoded as TLV tuples:

HMAC/CMAC Tuple (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.

6.3.2.3.44 MOB_SCN-RSP (scanning interval allocation response) message
A MOB_SCN-RSP message shall be transmitted by the BS either unsolicited or in response to a MOB_SCN-REQ message sent by an MS. A BS may transmit MOB_SCN-RSP to start MS scan reporting with or without scanning allocation. A BS may allocate the scanning allocation for MS scanning with Scanning type = 0b000, or MS noncontention association ranging with Scanning type = 0b010 or 0b011. The message shall be transmitted on the Basic CID.

For the compression of neighbor BSIDs through a reference to this message in MOB_SCN-REP, the BS may keep a mapping-table of neighbor BS MAC addresses and neighbor BS indexes transmitted through this message, for each MOB_SCN-RSP sequence number (Rsp_Seq_Num), where a BS index corresponds to the position of a BS in the MOB_SCN-RSP message, such that a BS Index of 0 identifies the first BS in the
MOB_SCN-RSP message and each next BS Index (incremented by 1) identifies the next BS in the message, according to the sequential order that the BSs appear in the message.

A BS index bitmap (Rsp_Bitmap_Index) in a MOB_SCN-REP message may be used to identify MOB_SCN-RSP BS indexes such that each bit position corresponds to a BS Index of the corresponding MOB_SCN_RSP message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last recommended BS, and BSs with BS Index greater than the last recommended BS are not recommended and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is recommended and a bit value of 0 indicates that the BS is not recommended.

The format of the MOB_SCN-RSP message is depicted in Table 147.

1: Bitmap of BS indexes for MOB_SCN-REQ is not used. |
| Report period                 | 8          | If Report mode is set to 0b01 or 0b11, this is the Report Period, in frames; otherwise this field is set to 0.  
For MS request denied (Scan Duration == 0), Report period is the number of frames that BS suggests to MS before transmitting next MOB_SCN-REQ. |

The following parameters shall be included in the MOB_SCN-RSP message:

**Scan duration**
Duration (in units of frames) where the MS may perform scanning or association for available BSs. When MOB_SCN-RSP is sent in response to MOB_SCN-REQ, setting Scan duration to zero indicates the request for an allocation of scanning interval is denied.

**Report mode**
0b00: No report  
0b01: Periodic report
Report period
The period of MS’s report of scanning result when the MS is required to report the value periodically or one-time. The period is calculated from the start of the first scan duration. If the BS sends an unsolicited MOB_SCN-RSP message without assignment of a scanning interval and the scan duration is set to zero, the period is calculated from the frame the MS receives the MOB_SCN-RSP message. For MS scanning request denied by MOB_SCN-RSP with Scan Duration set to zero, Report period is the number of frames that BS suggests to MS before transmitting next MOB_SCN-REQ.

Req_Seq_Num
One-bit sequence number for the MOB_SCN-REQ message associated with a MOB_SCN-REQ BS Index bitmap (Req_Bitmap_Index), where a bit position in this bitmap corresponds to a BS index of the MOB_SCN-REQ message and where a BS index corresponds to the position of a BS in the MOB_SCN-REQ message.

Rsp_Seq_Num
One-bit sequence number for the MOB_SCN-RSP message that is toggled for each new message and may be included in a MOB_SCN-REP message to identify the MOB_SCN-RSP message associated with a MOB_SCN-RSP BS Index bitmap (Rsp_Bitmap_Index), where a bit position in this bitmap corresponds to a BS index of the MOB_SCN-RSP message and where a BS index corresponds to the position of a BS in the MOB_SCN-RSP message. When an BS receives a MOB_SCN-REP message from an MS that includes Rsp_Seq_Num, the BS shall compare its stored value of Rsp_Seq_Num with the one included in the MOB_SCN-REP message and discard the MOB_SCN-REP message if there is a mismatch.

Use_Nbr_Bitmap_Index
Indicates if the bitmap of BS indexes for MOB_NBR-ADV is used.

Use_Req_Bitmap_Index
Indicates if the bitmap of BS indexes for MOB_SCN-REQ is used.

Nbr_Bitmap_Index
Bitmap of BS indexes for the corresponding MOB_NBR-ADV message where each bit position corresponds to a BS Index of the corresponding MOB_NBR-ADV message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last recommended BS, and BSs with BS Index greater than the last recommended BS are not reported and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is recommended and a bit value of 0 indicates that the BS is not recommended.

When Use_Req_Bitmap_Index equals 1, Nbr_Bitmap_Index only includes BSs included in the MOB_NBR-ADV message but not included in the corresponding MOB_SCN-REQ message.

Req_Bitmap_Index
Bitmap of BS indexes for the corresponding MOB_SCN_REQ message, where each bit position corresponds to a BS Index of the corresponding MOB_SCN_REQ message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last recommended BS, and BSs with BS Index greater than the last recommended BS are not reported and do not have a corresponding bit position in the bitmap.
This bitmap identifies recommended BSs that were included in the corresponding MOB_SCN-REQ message, including BSs that are included in the MOB_NBR-ADV message that were included in the MOB_SCN-REQ message.

**Report metric**
Bitmap indicator of trigger metrics that the serving BS requests the MS to report. The serving BS shall indicate only the trigger metrics agreed during SBC-REQ/RSP negotiation. Each bit indicates whether reports will be initiated by trigger based on the corresponding metric:

- Bit 0: BS CINR mean
- Bit 1: BS RSSI mean
- Bit 2: Relative delay
- Bit 3: BS RTD; this metric shall be only measured on serving BS/anchor BS
- Bits 4–7: Reserved; shall be set to zero

**Start Frame**
Represents the 8 least significant bits of the absolute frame number in which the first Scanning interval starts.

**Interleaving interval**
The period interleaved between Scanning Intervals when MS shall perform normal operation.

**Scan iteration**
The number of iterating scanning interval.

**Configuration Change Count for MOB_NBR-ADV**
The value of Configuration Change Count in MOB_NBR-ADV message referred in order to compress neighbor BSID.

**N_Recommended_BS_Index**
Number of neighboring BS to be scanned or associated, which are included in MOB_NBR-ADV message.

**Neighbor_BS_Index**
BS index corresponds to position of BS in MOB_NBR-ADV message.

**Scanning type**
Type of scanning or association used by the MS and coordinated by the serving BS (if scanning type ≥ 0b010).

**N_Recommended_BS_Full**
Number of neighboring BS to be scanned or associated that are using full 48 bits BSID.

**Recommended BSID**
Recommended BSID list for scan with or without association.

If Scanning type > 0b001, then the serving BS may request, over the backbone, from Recommended BS allocation of non-contention-based ranging opportunity for MS association activity. When conducting initial ranging to Recommended BS, MS shall use allocated non-contention-based ranging opportunity, if available.

**Rendezvous time**
This is offset, measured in units of frame duration (of the serving BS), when the corresponding Recommended BS is expected to provide non-contention-based ranging opportunity for the
MS. The offset is calculated from the frame where MOB_SCN-RSP message is transmitted. In case Scanning type = 0b000 or 0b001 the parameter is not applicable and shall be encoded as 0. The Recommended BS is expected to provide non-contention-based ranging opportunity at the frame specified by Rendezvous time parameter.

**CDMA code**
A unique code assigned to the MS, to be used for association with the neighbor BS. Code is from the initial ranging codeset.

**Transmission opportunity offset**
A unique transmission opportunity assigned to the MS, to be used for association with the target BS in units of symbol duration.

The MOB_SCN-RSP message may include the following parameters encoded as TLVs:

**Sleep Mode Reactivation Information (see 11.20.2)**

The MOB_SCN-RSP message shall include the following parameters encoded as TLV tuples:

**HMAC/CMAC Tuple (see 11.1.2)**
The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.45 MOB_SCN-REP (scanning result report) message

When the report mode is 0b10 (i.e., event triggered) in the most recently received MOB_SCN-RSP, the MS shall transmit a MOB_SCN-REP message to report the scanning results to its serving BS after each scanning period if the trigger condition is met. For a periodic report (i.e., Report Mode is 0b01) and for One-time Scan Report (Report Mode is 0b11), the MS reports the scanning results to its serving BS at the time indicated in the MOB_SCN-RSP message except when it is in the scanning interval. The MS shall include all available scanning results for the requested BSs specified in the said MOB_SCN-RSP message. The MS may transmit a MOB_SCN-REP message to report the scanning results to its serving BS at anytime. The message shall be transmitted on the Primary Management CID. (See Table 148.)

</tbody>
</table>
An MS shall generate MOB_SCN-REP messages in the format shown in Table 148. The following parameters shall be included in the MOB_SCN-REP message:

### Report mode
Action code for an MS’s scan report of its measurement:

- 0: Event triggered report
- 1: Periodic report according to Scan report period of MOB_SCN-RSP

### Report metric
Bitmap indicator of trigger metrics that the serving BS requests the MS to report. The serving BS shall indicate only the trigger metrics agreed during SBC-REQ/RSP negotiation. For each bit location, a value of 0 indicates the trigger metric is not included, while a value of '1' indicates the trigger metric is included in the message. The bitmap interpretation for the metrics shall be as follows:

- Bit 0: BS CINR mean
- Bit 1: BS RSSI mean
- Bit 2: Relative delay
- Bit 3: BS RTD; this metric shall be only measured on serving BS/anchor BS
- Bits 4–7: Reserved; shall be set to zero

### N_current_BSs
When FBSS/MDHO is supported, N_current_BSs is the number of BSs currently in the diversity set; when FBSS/MDHO is not supported or the MS has an empty diversity set, N_current_BSs is set to 1 (= serving /anchor BS).

### Rsp_Seq_Num
Sequence number for the MOB_SCN-RSP message associated with a MOB_SCN-RSP BS Index bitmap (Rsp_Bitmap_Index), where a bit position in this bitmap corresponds to a BS index of the MOB_SCN-RSP message and where a BS index corresponds to the position of a BS in the MOB_SCN-RSP message.

</table>
Use_Nbr_Bitmap_Index
Indicates if the bitmap of BS indexes for MOB_NBR-ADV is used.

Use_Rsp_Bitmap_Index
Indicates if the bitmap of BS indexes for MOB_SCN-RSP is used.

Nbr_Bitmap_Index
Bitmap of BS indexes for the corresponding MOB_NBR-ADV message where each bit position corresponds to a BS Index of the corresponding MOB_NBR-ADV message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last reported BS, and BSs with BS Index greater than the last reported BS are not reported and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is reported and a bit value of 0 indicates that the BS is not reported.

When Use_Rsp_Bitmap_Index equals 1, Nbr_Bitmap_Index only includes BSs included in the MOB_NBR-ADV message but not included in the corresponding MOB_SCN-RSP message.

Rsp_Bitmap_Index
Bitmap of indexes for the corresponding MOB_SCN-RSP message, where each bit position corresponds to a BS Index of the corresponding MOB_SCN-RSP message, the least significant bit corresponds to the first BS Index, each next significant bit corresponds to the next BS Index in sequential order, the most significant bit corresponds to the BS Index of the last reported BS, and BSs with BS Index greater than the last reported BS are not reported and do not have a corresponding bit position in the bitmap. Bitmap position bit value of 1 indicates that the BS is reported and a bit value of 0 indicates that the BS is not reported.

This bitmap identifies BSs included in the corresponding MOB_SCN-RSP message, including BSs that are included in the MOB_NBR-ADV message that were included in the MOB_SCN-RSP message.

Temp BSID
Diversity set member ID assigned to this BS. When the MS has an empty diversity set or FBSS/MDHO is not supported, Temp BSID shall be set to 0.

N_Neighbor_BS_Index
Number of neighboring BS reported in this message and which are included in MOB_NBR-ADV message.

N_Neighbor_BS_Full
Number of neighboring BS reported in this message that are using full 48 bits BSID.

For each neighbor BS included in this message, the following parameters shall be included:

Configuration Change Count for MOB_NBR-ADV
The value of Configuration Change Count in MOB_NBR-ADV message referred in order to compress neighbor BSID.

Neighbor_BS_Index
BS index corresponds to position of BS in MOB_NBR-ADV message.

Neighbor BSID
Same as the Base Station ID parameter in the DL-MAP message of neighbor BS.
According to Report metric that MS indicates, the MOB_SCN-REP message may include the following parameters:

**BS CINR mean**

The BS CINR Mean parameter indicates the CINR measured by the MS from the particular BS. The value shall be interpreted as a signed byte with units of 0.5 dB. The measurement shall be performed on the subcarriers of the frame preamble that are active in the particular BS’s segment and averaged over the measurement period.

**BS RSSI mean**

The BS RSSI Mean parameter indicates the Received Signal Strength measured by the MS from the particular BS. The value shall be interpreted as an unsigned byte with units of 0.25 dB, e.g., 0x00 is interpreted as –103.75 dBm. An MS shall be able to report values in the range –103.75 dBm to –40 dBm. The measurement shall be performed on the frame preamble and averaged over the measurement period.

**Relative delay**

This parameter indicates the delay of neighbor DL signals relative to the serving BS, as measured by the MS for the particular BS. The value shall be interpreted as a signed integer in units of samples.

**BS RTD**

The BS RTD parameter indicates the round trip delay (RTD) measured by the MS from the serving BS. RTD can be given by the latest time advance taken by MS. The value shall be interpreted as an unsigned byte with units of 1/Fs (see 10.3.4.3). This parameter shall be only measured on serving BS/anchor BS.

TLV tuples specified in 11.19 may be included into MOB_SCN-REP message. Information provided by N-th TLV of this type is related to N-th BS listed in the message.

The MOB_SCN-REP message shall include the following parameters encoded as TLV tuples:

**HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

**6.3.2.3.46 MOB_ASC-REP (association result report) message**

When association level 2 is used, the MS does not have to wait for RNG-RSP from the target BS after sending RNG-REQ or ranging code to the target BS. Instead, the RNG-RSP info may be sent by each target BS to the serving BS (over the backbone). The serving BS may aggregate all the RNG-RSP messages to a
single MOB_ASC-REP message, which the serving BS then sends to the MS. This message is transmitted using the Primary Management CID (see Table 149).

</tbody>
</table>

The following parameters shall be included in the MOB_ASC-REP message:
N_Recommended_BS_Index
Number of neighboring BSs reported in this message and which are included in MOB_NBR-ADV message. When the MS receives the MOB_ASC-REP message from BS, it shall compare the Configuration Change Count of the message with the one of the last received MOB_SCN-RSP message. If the MS detects a mismatch, it shall discard this message.

Configuration Change Count for MOB_NBR-ADV
The value of Configuration Change Count in MOB_NBR-ADV message referred in order to compress neighbor BSID.

Neighbor_BS_Index
BS index corresponds to position of BS in MOB_NBR-ADV message.

N_Recommended_BS_Full
Number of neighboring BSs reported in this message that are using full 48 bits BSID.

Neighbor_BS_ID
BSID of the neighboring BS with which the MS is associated.

Timing adjust
The time required to advance MS transmissions so frames arrive at the expected time instance at the neighbor BS.

Power level adjust
The power level offset adjustment required so that MS transmissions arrive at the desired level at the neighbor BS.

Offset frequency adjust
The relative frequency adjustment required so that MS transmissions arrive at the desired frequency at the neighbor BS.

Ranging status
Used to indicate whether MS ranging attempt is within acceptable limits of the neighbor BS.

Service level prediction
The service level prediction value indicates the level of service the MS can expect from this neighbor BS. The following encodings apply:

0 = No service possible for this MS.
1 = Some service is available for one or several service flows authorized for the MS.
2 = For each authorized service flow, a MAC connection can be established with QoS specified by the AuthorizedQoSParamSet.
3 = No service level prediction available.
6.3.2.3.47 MOB_BSHO-REQ (BS HO request) message

The BS may transmit a MOB_BSHO-REQ message when it wants to initiate an HO. An MS receiving this message may scan recommended neighbor BSs in this message. The message shall be transmitted on the Basic CID. See Table 150.

</table>
A BS shall generate MOB_BSHO-REQ messages in the format shown in Table 150. The following parameters shall be included in the MOB_BSHO-REQ message:

**Mode**
Indicates which HO mode is for this HO request.

0b000: HO request  
0b001: MDHO/FBSS request: Anchor BS update with CID update  
0b010: MDHO/FBSS request: Anchor BS update without CID update  
0b011: MDHO/FBSS request: Diversity set update with CID update  
0b100: MDHO/FBSS request: Diversity set update without CID update  
0b101: MDHO/FBSS request: Diversity set update with CID update for newly added BS  
0b110: MDHO/FBSS request: Diversity set update with CID update and CQICH allocation for newly added BS  
0b111: Reserved

**HO operation mode**
Indicate the operation mode of this HO request as initiated and prescribed by BS.

0: Recommended HO request  
1: Mandatory HO request. If HO operation mode is set to 1, BS shall include at least one recommended BS in the message (N_Recommended ≥ 1).

**Resource Retain Flag**
The Resource Retain Flag indicates whether the serving BS will retain or delete the connection information of the MS upon receiving MOB_HO-IND with HO_IND_type = 0b00. If the flag is set to 1, the serving BS will retain the MS’s connection information during the time in Resource Retain Time field. If Resource Retain Flag = 1 and Resource Retain Time is not included as a TLV item in the message, then the serving BS and MS shall use the System Resource Retain Time timer. If the flag is set to 0, the serving BS will discard the MS’s connection information.

**Unsolicited UL Grant for HO-IND flag**
The Unsolicited UL Grant for HO-IND flag indicates whether the serving BS will grant an unsolicited UL allocation for MS transmission of MOB_HO-IND message. If the Unsolicited
UL Grant for HO-IND flag is set to 1, the serving BS will grant an unsolicited UL allocation for MOB_HO-IND message after expiration of Handover Indication Readiness Timer (see 11.7.12.6).

If the Unsolicited UL Grant for HO-IND flag is set to 0, then the MS shall not expect any unsolicited UL grant.

**Action Time**

For HO, this value is defined as number of frames until the Target BS allocates a dedicated transmission opportunity for RNG-REQ message to be transmitted by the MS using Fast_Ranging_IE. Dedicated allocation for transmission of RNG-REQ means that channel parameters for that BS learned by the MS before HO stay valid and can be reused during actual Network Re-entry without preceding CDMA-based Ranging. Final Action Time shall be decided by the Serving BS based on the information obtained from potential Target BSs over the backbone network. A value of zero indicates no opportunity to allocate Fast Ranging IE in any candidate target BS.

For MDHO/FBSS, this is the time of update of Anchor BS and/or Diversity Set. A value of zero in this parameter signifies that this parameter shall be ignored.

For Mode = 0b00, for each recommended neighbor BS, the following parameters shall be included:

**Network Assisted HO supported**

Indicates that the BS supports Network Assisted HO, 1 = supported, 0 = not supported

**Neighbor BSID**

Same as the Base Station ID parameter in the DL-MAP message of neighbor BS. This may include the serving BS.

**Preamble index/ Subchannel Index**

For the OFDMA PHY this parameter defines the PHY-specific preamble for the neighbor BS. For the OFDM PHY the 5 LSB contain the DL subchannel index (as defined in Table 248) used in the neighbor BS’s sector. The 3 MSB shall be reserved and set to 0b000.

**Service level prediction**

The service level prediction value indicates the level of service the MS can expect from this BS. The following encodings apply:

0 = No service possible for this MS.
1 = Some service is available for one or several service flows authorized for the MS.
2 = For each authorized service flow, a MAC connection can be established with QoS specified by the AuthorizedQoSParamSet.
3 = No service level prediction available.

**HO process optimization**

HO Process Optimization is provided as part of this message is indicative only. HO process requirements may change at time of actual HO. For each Bit location, a value of 0 indicates the associated reentry management messages shall be required, a value of 1 indicates the reentry management message may be omitted. Regardless of the HO Process Optimization TLV settings, the target BS may send unsolicited SBC-RSP and/ or REG-RSP management messages:

Bit 0: Omit SBC-REQ/RSP management messages during reentry processing
Bit 1: Omit PKM Authentication phase except TEK phase during current reentry processing
Bit 2: Omit PKM TEK creation phase during reentry processing
Bit 3: Omit Network Address Acquisition management messages during current reentry processing
Bit 4: Omit Time of Day Acquisition management messages during current reentry processing
Bit 5: Omit TFTP management messages during current reentry processing
Bit 6: Full service and operational state transfer or sharing between serving BS and target BS (All static and dynamic context, e.g., ARQ window contents, timers, counters, state machines)
Bit 7: Omit REG-REQ/RSP management during current re-entry processing

For Mode != 0b000, the following parameters shall be included:

**N_new_Bs**
Number of new BSs that are recommended to be added to the diversity set of the MS.

**N_CID**
Number of CIDs that need to be allocated.

**TEMP BSID**
Index to diversity set for active BS ranging from 0 to 7.

**New CID**
The New CIDs shall be set as follows: the first CID in the list shall be Basic CID; the second CID in the list shall be Primary Management CID, the third CID in the list shall be Secondary Management CID if secondary management connection is established for the MS at the current serving BS. The remaining CIDs shall be Transport CIDs, Multicast Polling CIDs are enumerated by the ascending order of corresponding current SFIDs. The MS shall store the CIDs associated with the newly added BS and use the CIDs when the newly added BS becomes the anchor BS.

**N_SAIIDs**
Number of SAIDs that need to be assigned.

**New SAID**
New SAIDs are enumerated by the ascending order of corresponding current SAIIDs. The MS shall store the SAIDs associated with the newly added BS and use the SAIDs when the newly added BS becomes the anchor BS.

**HO_ID included indicator**
Indicates whether HO_ID is included in this message.

**HO_ID**
ID assigned for use in initial ranging to the target BS once this BS is selected as the target BS (see 11.5).

**Seamless HO mode flag**
Indicates whether Seamless HO is performed at the recommended neighbor BS. When the flag set to 1, the Pre-allocated Basic CID is included in the message.

**Pre-allocated Basic CID**
Basic CID allocated by recommended neighbor BS.
Seamless HO Ranging Initiation Deadline
Time allowed for the MS to transmit RNG-REQ at the target BS during seamless HO. The time
is specified in units of 10 msec. Time starts at the time the message it is contained in (i.e.,
BSHO-REQ/RSP) is transmitted.

TEK Lifetime
This parameter is used for setting the lifetime of the new TEKs at the target BS. See 7.2.2.2.6.1
for more details on how the lifetime of new TEKs at the target BS is calculated.

N_SAIDs
Number of SAIDs that need to be re-assigned at the target BS.

New SAID
New SAIDs are enumerated by the ascending order of corresponding current SAIDs.

AK Change Indicator
Indicates whether the authorization key being used should change when switching to a new
anchor BS. If set to 0, the MS should continue to use the AK currently in use; if set to 1, the MS
should use the AK derived for use with the new anchor BS.

The MOB_BSHO-REQ may contain the following TLV:

Resource Retain Time (see 11.15.1)

For Mode = 0b00, the MOB_BSHO-REQ may contain the following TLV:

Additional Action Time (see 11.15.3)
Indicates a specific action time for each Neighbor BS listed in this message. The action times
included in this TLV shall be ordered according to the Neighbor BS listed in this message.

The MOB_BSHO-REQ message shall include the following parameter encoded as TLV tuples:

HMAC/CMAC Tuple (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.
6.3.2.3.48 MOB_MSHO-REQ (MS HO request) message

The MS may transmit a MOB_MSHO-REQ message when it wants to initiate an HO. The message shall be transmitted on the Basic CID (see Table 151).

</table>
An MS shall generate MOB_MSHO-REQ messages in the format shown in Table 151. The following parameters shall be included in the MOB_MSHO-REQ message:

**Report metric**
Bitmap indicator of trigger metrics that the MS reports in this message. MS shall indicate only the trigger metrics agreed during SBC-REQ/RSP negotiation. For each bit location, a value of 0 indicates the trigger metric should not be included, while a value of 1 indicates the trigger metric should be included in the message. The bitmap interpretation for the metrics shall be:

- Bit 0: BS CINR mean
- Bit 1: BS RSSI mean
- Bit 2: Relative delay
- Bit 3: BS RTD; this metric shall be only measured on serving BS/anchor BS
- Bits 4–7: Reserved; shall be set to zero

### N_New_BS_Index
Number of neighboring BSs to be considered for handover, which are included in MOB_NBR-ADV message.

### N_New_BS_Full
The number of neighboring BSs to be considered for handover, which are identified by full 48 bit BSID.

</tbody>
</table>
For each recommended neighbor BS, the following parameters shall be included:

**Configuration Change Count for MOB_NBR-ADV**
The value of Configuration Change Count in MOB_NBR-ADV message referred in order to compress neighbor BSID.

**Neighbor BS Index**
BS index corresponds to position of BS in MOB_NBR-ADV message.

**Neighbor BSID**
Same as the Base Station ID parameter in the DL-MAP message of the neighbor BS.

**Preamble Index/ Subchannel Index**
For the OFDMA PHY this parameter defines the PHY-specific preamble for the neighbor BS. For the OFDM PHY the 5 LSB contain the DL subchannel index (as defined in Table 248) used in the neighbor BS’s sector. The 3 MSB shall be reserved and set to 0.

According to Report metric that MS indicates, the MOB_MSHO-REQ message includes the following parameters:

**BS CINR mean**
The BS CINR Mean parameter indicates the CINR in dB measured at the MS on the DL signal of a particular BS. The value shall be interpreted as a signed byte with the resolution of 0.5 dB. The measurement shall be performed on the subcarriers of the frame preamble that are active in the particular BS’s segment and averaged over the measurement period.

**BS RSSI mean**
The BS RSSI Mean parameter indicates the Received Signal Strength measured by the MS from the particular BS. The value shall be interpreted as an unsigned byte with units of 0.25 dB, e.g., 0x00 is interpreted as –103.75 dBm. An MS shall be able to report values in the range of –103.75 dBm to –40 dBm. The measurement shall be performed on the frame preamble and averaged over the measurement period.

**Relative delay**
This parameter indicates the delay of neighbor DL signals relative to the serving BS, as measured by the MS for the particular BS. The value shall be interpreted as a signed integer in units of samples.

**BS RTD**
The BS RTD parameter indicates the round trip delay (RTD) measured by the MS from the serving BS. RTD can be given by the latest time advance taken by MS. The value shall be interpreted as an unsigned byte with units of 1/Fs (see 10.3.4.3). This parameter shall be only measured on serving BS/anchor BS.

**Arrival Time Difference**
The Arrival Time Difference parameter indicates the delay of DL signal relative to the serving BS, as measured by the MS for the neighbor BS. For OFDM and OFDMA PHY mode, this value shall be interpreted as a signed fraction with a range of +7/8 to –1 one cyclic prefix time of the serving BS. A positive value indicates that the signal of the neighbor BS arrived after that of the serving BS (for example, the value of 0x02 indicates that the neighbor signal is delayed by 25% ±6.25% of the CP).
When the MS supports FBSS/MDHO and has a nonempty diversity set, the MS shall include the following parameters for each active BS. When the MS does not support FBSS/MDHO or has an empty active, the MS shall include the following parameters for the current serving BS.

**Temp BSID**
When the MS support FBSS/MDHO and has a nonempty diversity set, Temp BSID is the diversity set member ID. When the MS does not support FBSS/MDHO or has an empty diversity set, Temp BSID shall be set to 0.

**BS CINR mean**
The BS CINR Mean parameter indicates the CINR in dB measured at the MS on the DL signal of a particular BS. The value shall be interpreted as a signed byte with the resolution of 0.5 dB. The measurement shall be performed on the frame preamble and averaged over the measurement period.

The MOB_MSHO-REQ message shall include the following parameters encoded as TLV tuples:

**HMAC/CMAC Tuple** (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.49 MOB_BSHO-RSP (BS HO response) message

The BS shall transmit a MOB_BSHO-RSP message upon reception of MOB_MSHO-REQ message. The message shall be transmitted on the Basic CID. See Table 152.

</tr>
</tbody>
</table>
### Frame offset

The MS starts reporting at the frame of which the number has the same 3 LSB as the specified frame offset. If the current frame is specified, the MS should start reporting in eight frames.

### Duration (=d)

A CQI feedback is transmitted on the CQI channels indexed by the CQICH_ID for $10 \times 2^d$ frames.

- If $d == 0b000$, the CQI-CH is deallocated.
- If $d == 0b111$, the MS should report until the BS command for the MS to stop.

### MIMO_permutation_feedback_cycle

- $0b00 = \text{No MIMO and permutation mode feedback}$
- $0b01 = \text{the MIMO and permutation mode indication shall be transmitted on the CQICH indexed by the CQICH_ID every four CQICH transmission opportunities allocated to the MS in this message. The first indication is sent on the 4th CQICH transmission opportunity allocated to the MS in this message.}$
- $0b10 = \text{the MIMO mode and permutation mode indication shall be transmitted on the CQICH indexed by the CQICH_ID every eight CQICH transmission opportunities allocated to the MS in this message. The first indication is sent on the 8th CQICH transmission opportunity allocated to the MS in this message.}$
- $0b11 = \text{the MIMO mode and permutation mode indication shall be transmitted on the CQICH indexed by the CQICH_ID every 16 CQICH transmission opportunities allocated to the MS in this message. The first indication is sent on the 16th CQICH transmission opportunity allocated to the MS in this message.}$

### N_current_BSs

Number of BSs currently in the diversity set of the MS that are recommended to remain in the diversity set.

```c
for (i = 0; i < N_current_BSs; i++) {
    TEMP_BSID
}
```

### TEMP_BSID_Anchor

Temp BSID for the anchor BS.
A BS shall generate MOB_BSHO-RSP messages in the format shown in Table 152. The following parameters shall be included in the MOB_BSHO-RSP message:

**HO operation mode**
Indicate the operation mode of this HO response as prescribed by BS.

0: Recommended HO response.
1: Mandatory HO response. If HO operation mode is set to 1, BS shall include at least one recommended BS in the message (N_Recommended ≥ 1).

**Action Time**
This value is defined as the number of frames until the Target BS allocates, using the Fast Ranging IE, a dedicated transmission opportunity for a RNG-REQ message to be transmitted by the MS. A non-zero value of this parameter means that, if the MS re-enters the network at the Target BS, the MS may skip CDMA-based ranging and apply the channel parameters for the Target BS that the MS acquired before HO when sending the RNG-REQ message. This parameter is decided by the Serving BS based on the information obtained from potential Target BSs over the backbone network. A value of zero indicates no opportunity to allocate Fast Ranging IE in any candidate target BS.

For MDHO/FBSS, this is the time of update of Anchor BS and/or Diversity Set. A value of zero in this parameter signifies that this parameter shall be ignored.

For MS handover request not recommended (Mode == 0b111), Action Time is the number of frames that the BS suggests MS wait before transmitting a next MOB_MSHO-REQ or MOB_HO-IND. If the action timer is equal to 0, MS may transmit a revised MOB_MSHO-REQ or MOB_HO-IND immediately.

Action Time included in this message is calculated from the beginning of the frame where this message was received.
**Resource Retain Flag**

The Resource Retain Flag indicates whether the serving BS will retain or delete the connection information of the MS upon receiving MOB_HO-IND with HO_IND_type = 0b00. If the flag is set to 1, the serving BS will retain the MS’s connection information during the time in Resource Retain Time field. If Resource Retain Flag = 1 then the serving BS and MS shall use the System Resource Retain Time timer. If the flag is set to 0, the serving BS will discard the MS’s connection information.

For Mode = 0b000 for each recommended neighbor BS, the following parameters shall be included,

**Unsolicited UL Grant for HO-IND flag**

The Unsolicited UL Grant for HO-IND flag indicates whether the serving BS will grant an unsolicited UL allocation for MS transmission of MOB_HO-IND message. If the Unsolicited UL Grant for HO-IND flag is set to 1, the serving BS will grant an unsolicited UL allocation for MOB_HO-IND message after expiration of Handover Indication Readiness Timer (see 11.7.12.6).

If the Unsolicited UL Grant for HO-IND flag is set to 0, then the MS shall not expect any unsolicited UL grant.

**NeighborBSID**

Same as the Base Station ID parameter in the DL-MAP message of neighbor BS. This may include the serving BS.

**Preamble index/ Subchannel Index**

For the OFDMA PHY this parameter defines the PHY-specific preamble for the neighbor BS. For the OFDM PHY the 5 LSB contain the DL subchannel index (as defined in Table 248) used in the neighbor BS’s sector. The 3 MSB shall be reserved and set to 0.

**Service level prediction**

The service level prediction value indicates the level of service the MS can expect from this BS. The following encodings apply:

- 0 = No service possible for this MS
- 1 = Some service is available for one or several service flows authorized for the MS.
- 2 = For each authorized service flow, a MAC connection can be established with QoS specified by the AuthorizedQoSParamSet.
- 3 = No service level prediction available.

**HO process optimization**

HO Process Optimization is provided as part of this message is indicative only. HO process requirements may change at time of actual HO. For each Bit location, a value of 0 indicates the associated reentry management messages shall be required, a value of 1 indicates the reentry management message may be omitted. Regardless of the HO Process Optimization TLV settings, the target BS may send unsolicited SBC-RSP and/ or REG-RSP management messages:

- Bit 0:Omit SBC-REQ/RSP management messages during reentry processing
- Bit 1:Omit PKM Authentication phase except TEK phase during current reentry processing
- Bit 2:Omit PKM TEK creation phase during reentry processing
- Bit 3:Omit Network Address Acquisition management messages during current reentry processing
Bit 4: Omit Time of Day Acquisition management messages during current reentry processing
Bit 5: Omit TFTP management messages during current reentry processing
Bit 6: Full service and operational state transfer or sharing between serving BS and target BS (ARQ, timers, counters, MAC state machines, etc.)
Bit 7: Omit REG-REQ/RSP management during current re-entry processing

**HO_ID_included_indicator**
Indicates whether HO_ID is included in this message.

**Seamless HO mode flag**
Indicates whether Seamless HO is performed at the recommended neighbor BS. When the flag set to 1, the Pre-allocated Basic CID is included in the message.

**Pre-allocated Basic CID**
Basic CID allocated by recommended neighbor BS.

The MOB_BSHO-RSP may contain the following TLV:

**Resource Retain Time** (see 11.15.1)

For Mode = 0b00, the MOB_BSHO-RSP may contain the following TLV:

**Additional Action Time** (see 11.15.3)
Indicates a specific action time for each Neighbor BS listed in this message. The action times included in this TLV shall be ordered according to the Neighbor BS listed in this message.

The MOB_BSHO-RSP message shall include the following parameter encoded as TLV tuples:

**HMAC/CMAC Tuple** (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.

For Mode != 0b000, the following parameter shall be included:

**AK Change Indicator**
Indicates whether the authorization key being used should change when switching to a new anchor BS. If set to 0, the MS should continue to use the AK currently in use; if set to 1, the MS should use the AK derived for use with the new anchor BS.

For Mode 0b001, 0b011, 0b101, 0b110, New CID and New SAID are assigned as follows:

**New CID**
The New CIDs shall be set as follows: the first CID in the list shall be basic CID; the second CID in the list shall be primary management CID, the third CID in the list shall be Secondary Management CID if secondary management connection is established for the MS at the current serving BS. The remaining CIDs shall be transport CIDs, multicast CIDs are enumerated by the ascending order of corresponding current SFIDs. The MS shall store the CIDs associated with the newly added BS and use the CIDs when the newly added BS becomes the anchor BS.

**New SAID**
New SAIDs are enumerated by the ascending order of corresponding current SAIDs. The MS shall store the SAIDs associated with the newly added BS and use the SAIDs when the newly added BS becomes the anchor BS.
6.3.2.3.50 MOB_HO-IND (HO indication) message

An MS shall transmit a MOB_HO-IND message for final indication that it is about to perform an HO. When the MS cancels or rejects the HO, the MS shall transmit a MOB_HO-IND message with appropriate HO_IND_type field. If the MS rejects the target BS(s) offered by the Serving BS for handover, the MS may include its preferred target BS(s) in the message sent to the serving BS. The message shall be transmitted on the Basic CID. See Table 153.

Table 153—MOB_HO-IND message format (continued)
**Ranging Params valid indication**
Indicator that shows whether ranging parameters acquired by the MS during preceding Association with selected target BS are still valid. This indicator may be used by target BS in decision to allocate dedicated transmission opportunity by Fast_Ranging_IE.

0b00: No indication. BS ignores this field (Default)
0b01: MS ranging parameters for target BS, which is specified in this message are valid
0b10: MS has no valid ranging parameters for target BS, which is specified in this message
0b11: Reserved

**Target_BS_ID**
Same as the BSID parameter in the DL-MAP message of target BS.

**Preamble Index/ Subchannel Index**
For the OFDMA PHY this parameter defines the PHY-specific preamble for the target BS. For the OFDM PHY the 5 LSB contain the DL subchannel index (as defined in Table 248) used in the target BS sector. The 3 MSB shall be reserved and set to 0.

The MOB_HO-IND message may include the following parameter encoded as a TLV tuple if HO_IND-type is set to 0b10:

**Alternate_Target_BS** (see 11.15.2)
If the MS sends the MOB_HO-IND with HO_IND_type set to 0b10 (HO reject), the MS may send this TLV to indicate its preferred handoff target BS.

The MOB_HO-IND message shall include the following parameter encoded as TLV tuples:

**HMAC/CMAC Tuple** (see 11.1.2)
The HMAC/CMAC Tuple shall be the last attribute in the message.

### 6.3.2.3.51 MOB_PAG-ADV (BS broadcast paging) message

The MOB_PAG-ADV message shall be sent on the Broadcast CID or Idle Mode Multicast CID during the BS paging interval.

The format of the message is shown in Table 154.

<table>
<thead>
<tr>
<th><strong>Table 154—MOB_PAG-ADV message format</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Syntax</strong></td>
</tr>

</tr>
<tr>
<td>Paging Group ID</td>
</tr>
<tr>
<td>}</td>
</tr>
<tr>
<td>Num_MACs</td>
</tr>
</tbody>
</table>
A BS shall generate MOB_PAG-ADV including the following parameters:

**Paging Group ID (16 bit)**
One or more logical affiliation groupings of BS.

**MS MAC Address hash**
This is a 24-bit field used to hash the MS 48-bit MAC address. The hash value shall be the remainder of the division (Modulo 2) of the 48-bit MAC address multiplied by the polynomial D24 with the generator polynomial g(D) = D24+D23+D18+D17+D14+D11+D10+D7+D6+D5+D4+D3+D+1 (hex = 1864CFB) (Example: [MS 48-bit MAC address]= 00:D0:59:0F:E2:2E; hash would then be set to 0x51efe3).

**Action Code**
Paging action instruction to MS
- 0b00 = No action required
- 0b01 = Perform ranging to establish location and acknowledge message
- 0b10 = Enter network
- 0b11 = Reserved

**Reserved**
6 —

**Padding**
variable Padding bits to ensure octet aligned

**TLV Encoded Information**
variable TLV-specific

</tbody>
</table>

For OFDMA PHY, when a BS pages multiple MSs, the BS may assign dedicated CDMA codes to one or more MS being paged. The BS shall first list the MAC Address Hash of those MSs that are assigned dedicated CDMA codes, followed by the MSs that are not assigned dedicated CDMA codes.

For OFDMA PHY, the following TLV may be included in the MOB_PAG-ADV management message:

**CDMA code and transmission opportunity assignment** (see 11.17.1)
OFDMA-PHY-specific parameter used to indicate CDMA code and transmission opportunity assigned to one or more MSs being paged in this message. One CDMA code and transmission opportunity assignment in the TLV corresponds to one MS paged. The order of the assignments...
is the same as the order of appearance of MS MAC address hash except with action code “No Action Required” in this message.

For OFDMA PHY, the following TLV may be included in the MOB_PAG-ADV management message. If a CDMA code assignment TLV is included, the Page-Response window TLV shall be included. There shall be no more than one occurrence of the Page-Response window TLV.

**Page-Response window** (see 11.17.2)
OFDMA-PHY-specific parameter used to indicate the time window (in unit of frames) during which the MS shall transmit the CDMA code at the transmission opportunity assigned in the CDMA code and transmission opportunity assignment TLV. The start of the window is the next frame after receiving the MOB_PAG-ADV.

### 6.3.2.3.52 MBS_MAP (multicast and broadcast service map) message

The BS shall send an MBS_MAP message on the Broadcast CID to specify the location and size of multi-BS MBS data bursts which are located in DL permutation zones designated for MBS in frames that are from two to five frames in the future from the frame containing the MBS MAP message. If present, an MBS_MAP message shall be located at the first symbol and the first subchannel in the DL permutation zone for MBS. The MBS_MAP message format is presented in Table 155. This message includes the MBS_DATA_IE, Extended_MBS_DATA_IE, and MBS_DATA_Time_Diversity_IE, which define the access information for the MBS burst. See Table 155, Table 156, Table 157, and Table 158.

if(!byte boundary) {}
MBS DIUC Change Count
It is used to notify the Burst Profile used for multi-BS MBS data has been changed. If MBS_DIUC_Change_Count changes, MS should wait until receiving DCD message unless Downlink Burst Profile TLV is included in MBS_MAP message.

The following TLV may be included in MBS_MAP message:

Downlink Burst Profile
Downlink Burst Profile is used for the definition of MBS DIUC. The MBS DIUC overrides the DIUC in DCD message for the MBS portion of the frame. If MBS DIUC is not defined by MBS MAP message, DIUC in DCD message shall be used instead. See Table 156, Table 157, and Table 158.

MCID_Preallocation and Transmission Info (see 11.1.12.1)
MCID_Preallocation and Transmission Info is used by the BSs in one MBS-Zone to provide information about changes in mapping of current MCIDs in the selected other MBS Zones.

MCID-Continuity and Transmission Info (see 11.1.12.2)
MCID-Continuity and Transmission Info is used by the BSs in one MBS-Zone to show consistency of MCID’s mapping used in selected other MBS Zones. Both procedures of MCID update do not make any assumptions on the way the MCIDs were allocated.

Multicast CID
CID that is used for MBS connections.

Logical Channel ID
This field is used to distinguish logical MBS connections which belong to the same multicast CID. It is allocated to each logical MBS connection (i.e., MBS contents) in DSA-RSP message during dynamic service addition procedure as described in 11.13.35. See Table 159.

</table>
**OFDMA symbol offset**
This indicates the starting position of the region for HARQ-coded MBS Bursts allocated with the same MBS_Burst_Frame_Offset. The region begins from the first subchannel of the OFDM symbol and in this region, MBS bursts, indicated by MBS_DATA Time Diversity IE at the same MBS_MAP message, are allocated in a frequency-first, one-dimensional way in the order of MBS_DATA Time Diversity IE at a MBS_MAP message.

**# of Data Subbursts**
This indicates the number of Data Subbursts with the same MBS Burst Frame Offset that are specified in this MBS MAP message.

**$N_{EP}$ code, $N_{SCH}$ code**
The combination of $N_{EP}$ code and $N_{SCH}$ code indicates the number of allocated slots and scheme of coding and modulation for the DL burst.

**AI_SN**
Defines HARQ identifier sequence number. This is toggled between 0 and 1 on successfully transmitting each encoder packet with the same HARQ channel.

**SPID**
Defines subpacket identifier, which is used to identify the four subpackets generated from an encoder packet.

**ACID**
Defines HARQ channel identifier for TimeDiversity MBS packet. Each TimeDiversity MBS connection can have multiple HARQ channels, each of which may have an encoder packet transaction pending.

MBS_DATA Time Diversity IE presents when MBS only for HARQ-enabled MS is provided.

The MBS burst indicated by the MBS_DATA Time Diversity IE is encoded at the same way of HARQ, but it does not need the acknowledgement from MS.

**6.3.2.3.53 PMC_REQ (power control mode change request) message**
This subclause is applicable to the OFDM and OFDMA PHY modes. The decision of the change of the power control mode between the open-loop power control and closed-loop power control is done at BS and the decision is indicated by the PMC_RSP MAC message. Before the frame start specified in PMC_RSP, the MS shall transmit PMC_REQ in response to receipt of a PMC_RSP from the BS directing a change to UL power control mode. Further, PMC_REQ can be used to request to change the power control mode. On the receipt of the PMC_REQ (Confirmation = 0) from MS, BS may send PMC_RSP in T47. The closed- and open-loop power control schemes are described in 8.3.7.4 (for OFDM) and 8.4.10.3 (for OFDMA). Before the first PMC_RSP message from BS, the default power control mode shall be the closed power control scheme. See Table 160.
CID shall be the Basic CID of MS. MS shall generate the PMC_REQ message including the following parameters:

**Power control mode change**
- 0b00: Closed-loop power control mode.
- 0b01: Open-loop power control passive mode with Offset_SSperSS retention.
- 0b10: Open-loop power control passive mode with Offset_SSperSS reset.
- 0b11: Open-loop power control active mode.

**UL Tx power**
UL Tx power level for the burst that carries this header (11.1.1). When the Tx power is different from slot to slot, the maximum value is reported.

**Confirmation**
- 0: MS requests to change the power control mode.
- 1: MS confirms the receipt of PMC_RSP from BS.

### 6.3.2.3.54 PMC_RSP (power control mode change response) message

For OFDM and OFDMA PHY modes, PMC_RSP is sent from BS as a confirmation of MS’s UL power control change intention with PMC_REQ message or it is sent unsolicited manner to command MS to change the UL power control mode as indicated in the PMC_RSP. The MS should switch to the new power control mode as instructed by the BS through PMC_RSP. The BS may resend PMC_RSP to the MS if the BS fails to receive PMC_REQ (Confirmation = 1) from the MS. When the open-loop power control is indicated, Offset_BSperMS is included. When the closed-loop power control is indicated, power adjust can be signaled. Before the first PMC_RSP message from BS, the default power control mode shall be the closed power control scheme (see Table 161).
CID shall be the Basic CID of MS. MS shall generate the PMC_RSP message including the following parameters:

**Power control mode change**
- 0b00: Closed-loop power control mode
- 0b01: Open loop power control passive mode with Offset_SSperSS retention
- 0b10: Open-loop power control passive mode with Offset_SSperSS reset
- 0b11: Open-loop power control active mode

**Start frame**
6 LSBs of frame number when the indicated power control mode is activated. When it is the same as the current frame number, the mode change shall be applied from the current frame.

**Power adjust**
Signed integer, which expresses the change in power level (in multiples of 0.25 dB) that the MS shall apply to its current transmission power. When subchannelization is employed, the subscriber shall interpret the power offset adjustment as a required change to the transmitted power density.

**Offset_BSperMS**
Signed integer, which expresses the change in power level (in multiples of 0.25 dB) that the MS shall apply to the open-loop power control formula in 8.4.10.3.2.
subscriber shall interpret the power offset adjustment as a required change to the transmitted power density.

**Offset BS per MS**
Signed integer, which expresses the change in power level (in multiples of 0.25 dB) that the MS shall apply to the open-loop power control formula in 8.4.10.3.2.

### 6.3.2.3.55 OFDMA SUB-DL-UL-MAP message

The placement of SUB-DL-UL-MAP messages within a frame is shown in Figure 39.

![Figure 39—Submap burst](image)

This message shall only apply to OFDMA PHY.

The SUB-DL-UL-MAP message shall appear in a compressed form, in which the generic MAC header is omitted. This is indicated by setting the 3 MSBs of the first data byte in the PHY burst pointed by a SUB MAP pointer IE to 1 (an invalid combination for a generic MAC header). The burst containing the SUB-DL-UL MAP message shall not contain any other messages.
The SUB-DL-UL-MAP format is presented in Table 162.

</tr>
</tbody>
</table>

**Map message length**

The length of the submap message in bytes including the SUB-DL-UL-MAP indicator and the CRC. To avoid ambiguity with the stuff byte (0xFF), the length is limited to 991 bytes.
HARQ ACK offset indicator
A field that indicates the inclusion of HARQ offsets. If this field is 0, then the ACK offsets shall be follow the last allocation made by previous maps. An MS that failed to decode any of the previous maps shall disregard all HARQ allocations made by this map, if HARQ ACK offset indicator is 0.

DL HARQ ACK offset
Indicates the ACK channel in the ACKCH Region that corresponds to the first HARQ-enabled DL burst specified in this map message. If more than one ACK region is defined, the DL HARQ ACK offset applies to the ACK region indexed by ACK region index.

ACK region index
The index of the ACK region associated with all DL HARQ bursts defined in this sub-map (FDD/H-FDD only).

0—First ACK region
1—Second ACK region.

For TDD mode this bit shall be set to 0. The ACK offset applies to this ACK region only, and all the H-ARQ bursts defined in the sub map should have a matching ACK region index defined in the HARQ DL MAP IE (see 8.4.5.3.21).

UL HARQ ACK offset
Indicates the ACK bit index in the DL HARQ ACK IE that corresponds to the first HARQ-enabled UL burst specified in this map message.

RCID_TYPE
The RCID type used for RCID IEs specified in DL-MAP IEs that are described in this SUB-DL-UL-MAP.

DL IE Count
The number of DL-MAP IEs.

A CCITT CRC 16 value is appended to the end of the SUB-DL-UL-MAP message. The CRC is computed across all bytes of the SUB-DL-UL-MAP message.

SUB-DL-UL-MAP message shall be pointed only through compressed DL MAP.

The order of DL-MAP IEs in the SUB-DL-UL-MAP message shall conform to the order defined for the DL-MAP message in 6.3.2.3.2.

The logical order in which MAC PDUs are mapped to the PHY bursts in the DL is defined as the order of increasing start time of all PHY bursts in the frame regardless of the MAP message in which they are described. If two or more PHY bursts have the same start time, the logical order is determined according to the order of appearance in the concatenation of DL-MAP and all SUB-DL-UL-MAP messages.

The logical order in which MAC PDUs are mapped to the PHY bursts in the UL is defined as the order of UL-MAP IEs in the SUB-DL-UL-MAP message.

The SUB-DL-UL-MAP message can be located in the first zone of the frame or when supported by the relevant MSs, in any of the zones within the frame. The sub-map capability for the first zone or other zones are specified and negotiated using SBC-REQ/RSP messages. In each zone, the SUB-DL-UL-MAP messages shall be allocated consecutively using the same uni-dimensional frequency-first slot mapping order used for the DL-MAP and HARQ MAP bursts. For the first zone in the frame, the first burst containing a
SUB-DL-UL-MAP message shall be allocated immediately following the bursts containing HARQ MAP messages, or following the compressed DL-MAP and appended compressed UL-MAP if no HARQ MAPs exist in the frame. For all subsequent zones, the first burst containing a SUB-DL-UL-MAP message shall be allocated starting at the first subchannel of the first OFDMA symbol in the zone. DL-MAP IEIs that appear in an SUB-DL-UL-MAP message shall only describe allocations whose starting OFDMA symbol is equal to or later than the first OFDMA symbol of the zone in which the SUB-DL-UL-MAP message is located. The bursts containing the SUB-DL-UL-MAP messages shall only be described by a SUB-MAP Pointer IE. This IE (if exists) shall immediately follow a STC_Zone_IE to describe SUB-DL-UL-MAP messages that are located in that zone. If SUB-DL-UL-MAP messages are located in the first zone, this IE shall immediately follow the DL IE count of compressed MAP.

The INC_CID flag shall be reset to 0 in the beginning of each SUB-DL-UL-MAP message.

Each SUB-DL-UL-MAP terminates the effect of any previous DL physical modifier, i.e., each SUB-DL-UL-MAP starts with no physical modifier. The first UL-MAP-IE in each SUB-DL-UL-MAP terminates the effect of any previous UL physical modifier.

All DL and UL Zone Switch IEIs (Extended DIUC 0x01, Extended UIUC 0x04) shall be defined in the main DL and UL MAPs. SUB-DL-UL-MAP shall comply with the main DL and UL MAP zone switch. The SUB-DL-UL-MAP shall not include the DL Zone Switch IE. Instead, the zone shall be identified by the symbol number (indicated in DL-MAP IE and other IEIs defining allocations).

The zone in which an UL allocation occurs is identified by the OFDMA Symbol Offset field in the SUB-DL-UL-MAP or the UL Allocation Start IE (see 8.4.5.4.13). Allocations within a non-AAS zone shall start at the subchannel/symbol offsets defined by the SUB-DL-UL-MAP or UL Allocation Start IE. Allocations made in an UL AAS zone or UL AMC zone shall be defined by the slot offset field of the UL-MAP IE referenced to the start of the AAS zone or UL AMC zone. In this case, the subchannel/symbol offset is only used to specify that the allocation occurs in the AAS zone or UL AMC zone and is not used as a starting point for the UL allocation.

The DL-MAP IEIs in the SUB-DL-UL-MAP shall be ordered in the increasing order of the transmission start time of the relevant PHY burst/allocation. The UL allocations in the SUB-DL-UL-MAP shall be ordered in increasing order of zones.

The maximum number of SUB-DL-UL-MAP messages per frame is three.

SUB-DL-UL-MAP message shall be used only with compressed DL and appended UL MAP structure.

**6.3.2.3.56 MIMO precoding setup/tear-down messages**

The BS can setup long-term precoding with feedback from a particular MS by sending the MAC management message PRC-LT-CTRL to the MS. The BS can also use the same MAC management message to tear-down the long-term precoding with feedback.

The precoding feedback delay of the BS, in number of frames, should be signaled from the BS to the MS in the PRC-LT-CTRL MAC management message. See Table 163.
6.3.2.3.57 MIH Payload Transfer (MOB_MIH-MSG) message

This message shall be transmitted on the Primary Management connection.

### Table 164—MOB_MIH-MSG message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOB_MIH-MSG_Message_Format( ) {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>Management Message Type = 67</td>
<td>8 bits</td>
<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>variable</td>
<td>TLV Specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The MOB_MIH-MSG shall include the following parameters as encoded as TLV tuples:

- **MIHF Frame** (see 11.1.11)
- **HMAC/CMAC Tuple** (see 11.1.2)

The HMAC/CMAC Tuple shall be the last attribute in the message.

The following parameters may be included in the MOB_MIH-MSG message:

- **MIHF frame type** (see 11.1.11.2)

  The MIHF frame type TLV indicates the service type of the MIHF frame TLV.

6.3.2.3.58 Service Identity Information (SII-ADV) message

A BS may use the SII-ADV message to broadcast a list of Network Service Provider (NSP) Identifiers. The message may be broadcast periodically without solicitation. The SII-ADV message may also be sent in response to a SS requesting NSP information (see 6.3.2.3.23). This message is sent from the BS to all SSs on the fragmentable broadcast CID. Assignment method, administration, and usage of NSP IDs are outside the scope of this standard. The list of NSP IDs to be included in this message and the message transmission
frequency are programmable. The BS may use the SII-ADV message to deliver IEEE 802.21 MIHF frame, which carries query response.

### Table 165—Service Identity Information (SII-ADV) message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SII-ADV () {}</td>

<td>—</td>
</tr>
<tr>
<td>TLV Encoded Information</td>
<td>Variable</td>
<td>TLV specific</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The following parameters may be included in the SII-ADV message; at least one TLV shall be included in an SII-ADV message:

- **NSP List TLV** (see 11.1.10.1)
  The NSP LIST TLV is a TLV that contains one or more Network Service Provider 24 bit Identifiers.

- **Verbose NSP Name List** (see 11.1.10.2)
  List of the verbose names of the NSPs. Verbose NSP Name List shall only be included in the message if NSP List TLV is also included in the message.

- **Query ID** (see 11.1.11.3)
  The Query ID TLV is used to correlate the response encapsulated in the MIHF frame carried in the MIHF frame TLV with a query previously sent by an MS within the broadcast area of the BS. It may be ignored by all other MSs.

- **MIHF frame type** (see 11.1.11.2)
  The MIHF frame type TLV indicates the service type of the MIHF frame TLV.

- **MIHF frame** (see 11.1.11.1)
  The encapsulated MIH response.

### 6.3.2.3.59 Location Based Services (LBS-ADV) message

A BS may use the LBS-ADV message to broadcast the LBS information. The message may be broadcast periodically without solicitation. This message is sent from the BS to all MSs on a broadcast CID (see Table 166).

### Table 166—Location-Based Services (LBS-ADV) message format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bits)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>LBS-ADV_Message_Format ( ) {}</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td><strong>Management message type = 69</strong></td>

</tr>
<tr>
<td>Length</td>
<td>8</td>
<td>Length of information pertaining to the transmitting BS</td>
</tr>
<tr>
<td>TLV encoded information</td>
<td>variable</td>
<td>—</td>
</tr>
</tbody>
</table>
The LBS-ADV message may include the following TLV:

**Absolute Position (Long Format) TLV** (see 11.21.1)
The transmitting BS’s coordinates. This TLV shall only be used for the transmitting BS and if the Absolute Position (Short Format) TLV is not used.

**Absolute Position (Short Format) TLV** (see 11.21.2)
The transmitting BS’s coordinates. This TLV shall only be used for the transmitting BS and if the Absolute Position (Long Format) TLV is not used.

**Relative Position TLV** (see 11.21.3)
A Neighbor BS’s coordinates. When this TLV is included it provides the position of a neighbor BS relatively to the transmitting BS.
GPS Time TLV (see 11.21.4)
Information about GPS time and time accuracy.

Frequency Accuracy TLV (see 11.21.5)
Information about the frequency accuracy. This TLV should only be included once in the message

6.3.3 Construction and transmission of MAC PDUs

The construction of a MAC PDU is illustrated in Figure 40.

Figure 40—Construction of a MAC PDU
6.3.3.1 Conventions

Data shall be transmitted in accordance with the following rules:

a) Fields of MAC messages and TLV encodings are transmitted in the same order as they appear in the corresponding tables in this standard.

b) Fields of MAC messages and fields of TLV encodings, which are specified in this standard as binary numbers (including CRC and HCS), are transmitted as a sequence of their binary digits, starting from MSB. Bit masks (for example, in ARQ) are considered numerical fields. TLV encodings are transmitted in the order of Type, Length and Value. If the Value of a TLV or a field within the TLVs Value is explicitly specified as a numbered sequence of bits, then the order of transmission shall be from highest sequence number to lowest sequence number. For signed numbers MSB is allocated for the sign. Length field in the “definite form” of ITU-T X.690 is also considered a numerical field.

c) Fields specified as SDUs or SDU fragments (for example, MAC PDU payloads) are transmitted in the same order of bytes as received from upper layers.

d) Fields specified as strings are transmitted in the order of symbols in the string.

In cases c) and d), bits within a byte are transmitted in the order “MSB first.”

6.3.3.2 Concatenation

Multiple MAC PDUs may be concatenated into a single transmission in either the UL or DL directions. Figure 41 illustrates this concept for an UL burst transmission. Since each MAC PDU is identified by a unique CID, the receiving MAC entity is able to present the MAC SDU (after reassembling the MAC SDU from one or more received MAC PDUs) to the correct instance of the MAC SAP. MAC management messages, user data, and BR MAC PDUs may be concatenated into the same transmission.

6.3.3.3 Fragmentation

Fragmentation is the process by which a MAC SDU (or MAC management message) is divided into one or more MAC PDUs. This process is undertaken to allow efficient use of available bandwidth relative to the QoS requirements of a connection’s service flow. Capabilities of fragmentation and reassembly are mandatory.

The authority to fragment traffic on a connection is defined when the connection is created by the MAC SAP. Fragmentation may be initiated by a BS for DL connections and by an SS for UL connections.

The size of the FSN field in FSHs is fixed per connection. The fragmentable broadcast connection shall use 11-bit FSN. The BS and SS shall support 11-bit FSN. The BS and SS may support 3-bit FSN. All management connections shall use 11-bit FSN. The size of the FSN used on non-ARQ fragmentable transport connections is determined during connection setup (see 11.13.21).
Fragments are tagged with their position in their parent SDU in accordance with Table 167.

### Table 167—Fragmentation rules

<table>
<thead>
<tr>
<th>Fragment</th>
<th>Fragmentation control (FC)</th>
</tr>
</thead>
<tbody>
<tr>
<td>First Fragment</td>
<td>10</td>
</tr>
<tr>
<td>Continuing Fragment</td>
<td>11</td>
</tr>
<tr>
<td>Last Fragment</td>
<td>01</td>
</tr>
<tr>
<td>Unfragmented</td>
<td>00</td>
</tr>
</tbody>
</table>

#### 6.3.3.3.1 Non-ARQ connections

For non-ARQ connections, fragments are transmitted once and in sequence. The sequence number assigned to each fragment allows the receiver to recreate the original payload and to detect the loss of any intermediate fragments. A connection may be in only one fragmentation state at any given time.

Upon loss, the receiver shall discard all MAC PDUs on the connection until a new first fragment is detected or a nonfragmented MAC PDU is detected.

#### 6.3.3.3.2 ARQ-enabled connections

For ARQ-enabled connections, fragments are formed for each transmission by concatenating sets of ARQ blocks with adjacent sequence numbers (see 6.3.4.2). The BSN value carried in the FSH is the BSN for the first ARQ block appearing in the segment.

#### 6.3.3.4 Packing

If packing is turned on for a connection, the MAC may pack multiple MAC SDUs into a single MAC PDU. Packing makes use of the connection attribute indicating whether the connection carries fixed-length or variable-length packets. The transmitting side has full discretion whether to pack a group of MAC SDUs in a single MAC PDU. The capability of unpacking is mandatory.

The construction of PDUs varies for ARQ and non-ARQ connections with respect to packing and fragmentation syntax. The packing and fragmentation mechanisms for both the ARQ and non-ARQ connections are specified in 6.3.3.4.1 through 6.3.3.4.3.

#### 6.3.3.4.1 Packing for non-ARQ connections

##### 6.3.3.4.1.1 Packing fixed-length MAC SDUs

For connections that do not use ARQ and are indicated by the fixed-length versus variable-length SDU indicator (11.13.14), to carry fixed-length MAC SDUs, the packing procedure described in this subclause may be used. For all other non-ARQ connections, the variable-length packing algorithm described in 6.3.3.4.2 shall be used.

For packing with fixed-length blocks, the Request/Transmission Policy (11.13.11) shall be set to allow packing and prohibit fragmentation, and the SDU size (11.13.15) shall be included in DSA-REQ message when establishing the connection. The length field of the MAC header implicitly indicates the number of MAC SDUs packed into a single MAC PDU. If the MAC SDU size is n bytes, the receiving side can unpack...
simply by knowing that the length field in the MAC header will be \( n \times k + j \), where \( k \) is the number of MAC SDUs packed into the MAC PDU and \( j \) is the size of the MAC header and any prepended MAC subheaders. A MAC PDU containing a packed sequence of fixed-length MAC SDUs would be constructed as in Figure 42. Note that there is no added overhead due to packing in the fixed-length MAC SDU case, and a single MAC SDU is simply a packed sequence of length \( I \).

\[
\text{MAC header} \quad \text{LEN} = n \times k + j
\]

\[
\text{Fixed-length MAC SDU} \quad \text{length} = n
\]

\[
\text{Fixed-length MAC SDU} \quad \text{length} = n
\]

\[
\text{Fixed-length MAC SDU} \quad \text{length} = n
\]

\[
\text{Fixed-length MAC SDU} \quad \text{length} = n
\]

\[
\text{Figure 42—Packing fixed-length MAC SDUs into a single MAC PDU}
\]

### 6.3.3.4.1.2 Packing variable-length MAC SDUs

When packing variable-length SDU connections, such as IEEE 802.3/Ethernet, the \( n \times k + j \) relationship between the MAC header’s Length field and the higher layer MAC SDUs no longer holds. This necessitates indication of where one MAC SDU ends and another begins. In the variable-length MAC SDU case, the MAC attaches a PSH to each MAC SDU. This subheader is described in 6.3.2.2.3.

A MAC PDU containing a packed sequence of variable-length MAC SDUs is constructed as shown in Figure 43 where PSH_LEN is the length of the packing subheader. If more than one MAC SDU is packed into the MAC PDU, the Type field in the MAC header indicates the presence of PSHs. Note that unfragmented MAC SDUs and MAC SDU fragments may both be present in the same MAC PDU (see Figure 44).

\[
\text{MAC header} \quad \text{LEN} = 000010b
\]

\[
\text{Type} = 000010b
\]

\[
\text{PSH} \quad \text{Length} = a + \text{PSH}_\text{LEN}
\]

\[
\text{variable-length MAC SDU} \quad \text{length} = a
\]

\[
\text{variable-length MAC SDU} \quad \text{length} = b
\]

\[
\text{variable-length MAC SDU} \quad \text{length} = c
\]

\[
\text{Figure 43—Packing variable-length MAC SDUs into a single MAC PDU}
\]

Simultaneous fragmentation and packing allows efficient use of the airlink, but requires guidelines to be followed so it is clear which MAC SDU is currently in a state of fragmentation. To accomplish this, when a PSH is present, the fragmentation information for individual MAC SDUs or MAC SDU fragments is contained in the corresponding PSH. If no PSH is present, the fragmentation information for individual MAC SDU fragments is contained in the corresponding FSH. This is shown in Figure 44, where PSH_LEN is the length of the packing subheader.
Note that while it is legal to have continuation fragments packed with other fragments, the circumstances for creating continuation fragments would preclude this from happening.

### 6.3.3.4.2 Packing for ARQ-enabled connections

The use of PSHs for ARQ-enabled connections is similar to that for non-ARQ connections as described in 6.3.3.4.1.2, except that ARQ-enabled connections shall set the Extended Type bit (see Table 6) in the generic MAC header to 1. If packing is turned on for a connection, the MAC may pack multiple MAC SDUs into a single MAC PDU. The transmitting side has full discretion whether to pack a group of MAC SDUs and/or fragments in a single MAC PDU.

The packing of variable-length MAC SDUs for the ARQ-enabled connections is similar to that of non-ARQ connections, when fragmentation is enabled. The BSN of the PSH shall be used by the ARQ protocol to identify and retransmit ARQ blocks.

For ARQ-enabled connections, when the type field indicates PSHs are in use, fragmentation information for each individual MAC SDU or MAC SDU fragment is contained in the associated PSH. When the type field indicates that packing is not in use, fragmentation information for the MAC PDU’s single payload (MAC SDU or MAC SDU fragment) is contained in the FSH appearing in the message. Figure 45 illustrates the use of FSH without packing.
Figure 46 illustrates the structure of a MAC PDU with ARQ PSHs. Each of the packed MAC SDU or MAC SDU fragments or ARQ feedback payload requires its own PSH and some of them may be transmissions while others are retransmissions.

### Table 168—ARQ Feedback Payload format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARQ_Feedback_Payload_Format() {</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>do</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>ARQ_Feedback_IE(last)</td>
<td>variable</td>
<td>Insert as many as desired, until last == TRUE. See 6.3.4.2.</td>
</tr>
<tr>
<td>until (last)</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The presence of an ARQ Feedback Payload in a MAC PDU is indicated by the value of the ARQ Feedback Payload bit in the Type field (see Table 6) in the generic MAC header. When present, the first packed payload shall be the ARQ Feedback Payload. The PSH preceding the ARQ Feedback Payload indicates the
total length of the payload including the PSH and all ARQ Feedback IEs within the payload. The FSN/BSN field of the PSH shall be ignored for the ARQ Feedback Payload and the FC bits shall be set to 00.

6.3.3.5 CRC calculation

A service flow may require that a CRC be added to each MAC PDU carrying data for that service flow (11.13.11). In this case, for each MAC PDU with HT = 0, a CRC32 (as defined in 6.3.3.5.1 for SC and OFDM mode and 6.3.3.5.2 for OFDMA mode), shall be appended to the payload of the MAC PDU; i.e., request MAC PDUs are unprotected. The CRC shall cover the generic MAC header and the payload of the MAC PDU. The CRC shall be calculated after encryption; i.e., the CRC protects the generic header and the ciphered payload.

6.3.3.5.1 CRC32 calculation for SC and OFDM mode

The data (input) bytes shall be flipped (for each byte exchange bit0 ↔ bit7, bit1 ↔ bit6, bit2 ↔ bit5, and bit3 ↔ bit4).

The CRC32 shall be calculated using the following standard generator polynomial of degree 32:

\[ G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \]

(where, the hexadecimal representation of truncated \( G(x) \) is “0x04c11db7”)

The CRC32 is the 1’s complement of the sum (modulo 2) of the following:

a) The remainder of \( x^k (x^{31} + x^{30} + x^{29} + \ldots + x^2 + x + 1) \) divided (modulo 2) by \( G(x) \), where \( k \) is the number of bits in the input data, and

b) The remainder after multiplication of the bit-flipped input data (treated as a polynomial) by \( x^{32} \) and then division by \( G(x) \).

The CRC32 field shall then be transmitted bit-flipped commencing with the most significant byte. (The first transmitted byte will have in its bit 7 the coefficient of \( x^{24} \) and in bit 0 the coefficient of \( x^{31} \). The fourth byte will have the coefficient of \( x^0 \) in bit 7 and the coefficient of \( x^7 \) in bit 0).

As a typical implementation, at the transmitter, the initial remainder of the division is preset to all 1s and is then modified by division of the bit-flipped data by the generator polynomial \( G(x) \). The 1’s complement of this remainder is then bit flipped byte after byte when transmitted, with the most significant byte first.

At the receiver, the initial remainder is preset to all 1s and the input bytes shall be flipped first and then treated as coefficient of a polynomial. When divided by \( G(x) \), this polynomial shall results in the absence of transmission errors, in a unique nonzero remainder value. The unique remainder value is the polynomial:

\[ x^{31} + x^{30} + x^{26} + x^{25} + x^{24} + x^{18} + x^{15} + x^{14} + x^{12} + x^{11} + x^{10} + x^8 + x^6 + x^5 + x^4 + x^3 + x + 1 \]

(or as its hexadecimal representation 0xC704DD7B)

6.3.3.5.1.1 CRC32 test vectors for SC and OFDM mode

The following is an example of CRC calculation in SC and OFDM mode:

Generic MAC header (Hex) = 40 40 1A 06 C4 5A
Payload (Hex) = BC F6 57 21 E7 55 36 C8 27 A8 D7 1B 43 2C A5 48
CRC32 for SC and OFDM mode (Hex) = CB B6 5F 48
6.3.3.5.2 CRC32 calculation for OFDMA mode

The data (input) bytes shall not be flipped as in OFDM mode.

The CRC32 shall be calculated using the following standard generator polynomial of degree 32:

\[ G(x) = x^{32} + x^{26} + x^{23} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 \]

(where, the hexadecimal representation of truncated \( G(x) \) is “0x04c11db7”)

At the transmitter, the following procedure is applied:

a) First 32 bits are complemented, which is equivalent to setting the initial value of the CRC register as 0xFFFFFFFF.

b) The first bit of the first field (MSB of the first byte of the MAC header) corresponds to the \( x^{n-1} \) term and the last bit of the last field corresponds to the \( x^0 \) term, where \( n \) is the number of bits in the input data sequence.

c) The resulting polynomial multiplied by \( x^{32} \) is divided by \( G(x) \).

d) The remainder bit sequence is complemented.

e) The 32 bits of the CRC value are placed in the CRC field so that the \( x^{31} \) term is the left-most bit of the first byte, and the \( x^0 \) term is the right most bit of the last byte.

f) The resulting CRC field is sent MSB first (6.3.3.1).

At the receiver, the initial remainder is preset to all 1s and the input bytes shall be fed into the CRC engine MSB first. When divided by \( G(x) \), this polynomial shall result in the absence of transmission errors, in a unique nonzero remainder value. The unique remainder value is the polynomial:

\[ x^{31} + x^{30} + x^{26} + x^{25} + x^{24} + x^{18} + x^{15} + x^{14} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^3 + x + 1 \]

(or as its hexadecimal representation 0xC704DD7B)

6.3.3.5.2.1 CRC32 test vectors for OFDMA mode

The following is an example of CRC calculation in OFDMA mode:

Generic MAC header (Hex) = 40 40 1A 06 C4 5A
Payload (Hex) = BC F6 57 21 E7 55 36 C8 27 A8 D7 1B 43 2C A5 48
CRC32 for OFDMA mode (Hex) = 1B D1 BA 21

6.3.3.6 Encryption of MAC PDUs

When transmitting a MAC PDU on a connection that is mapped to an SA, the sender shall perform encryption and data authentication of the MAC PDU payload as specified by that SA. When receiving a MAC PDU on a connection mapped to an SA, the receiver shall perform decryption and data authentication of the MAC PDU payload, as specified by that SA.

The generic MAC header shall not be encrypted. The header contains all the encryption information [EC field, EKS (encryption key sequence) field, and CID] needed to decrypt a payload at the receiving station. This is illustrated in Figure 47.
Two bits of a MAC header contain a key sequence number. Note that the keying material associated with an SA has a limited lifetime, and the BS periodically refreshes an SA’s keying material. The BS manages a 2-bit key sequence number independently for each SA and distributes this key sequence number along with the SA’s keying material to the client SS. The BS increments the key sequence number with each new generation of keying material. The MAC header includes this sequence number to identify the specific generation of that SA keying material being used to encrypt the attached payload. Being a 2-bit quantity, the sequence number wraps around to 0 when it reaches 3.

Comparing a received MAC PDU’s key sequence number with what it believes to be the “current” key sequence number, the SS or the BS can easily recognize a loss of key synchronization with its peer. An SS shall maintain the two most recent generations of keying material for each SA. Keeping on hand the two most recent key generations is necessary for maintaining uninterrupted service during an SA’s key transition.

Encryption of the payload is indicated by the EC bit field. A value of 1 indicates the payload is present and encrypted and the EKS field contains meaningful data. A value of 0 indicates the payload is not encrypted or not present. Any MAC PDU containing an unencrypted payload received on a connection mapped to an SA requiring encryption shall be discarded.

**6.3.3.7 Padding**

Within a data burst, the unused portion shall be initialized to a known state. This may be accomplished by setting each unused byte to the stuff byte value (0xFF). If the size of the unused region is at least the size of a MAC header, the region may also be initialized by formatting the unused space as a MAC PDU. When doing so, the MAC header CID field shall be set to the value of the Padding CID (see Table 558); the CI, EC, HT, and Type fields shall be set to zero; the length field shall be set to the number of unused bytes (including the size of the MAC header created for the padding MAC PDU) in the data burst; and the HCS shall be computed in the normal way.

**6.3.4 ARQ mechanism**

ARQ shall not be used with the PHY specification defined in 8.1. If ARQ is supported, then support of the ‘cumulative ACK entry’ and at least one of other acknowledgement types is mandatory.

The ARQ mechanism is a part of the MAC, which is optional for implementation. When implemented, ARQ may be enabled on a per-connection basis. The per-connection ARQ shall be specified and negotiated during connection creation. A connection cannot have a mixture of ARQ and non-ARQ traffic. Similar to other properties of the MAC protocol the scope of a specific instance of ARQ is limited to one unidirectional connection.

For ARQ-enabled connections, enabling of fragmentation is optional. When fragmentation is enabled, the transmitter may partition each SDU into fragments for separate transmission based on the value of the...
ARQ_BLOCK_SIZE parameter. When fragmentation is not enabled, the connection shall be managed as if fragmentation was enabled. In this case, regardless of the negotiated block size, each fragment formed for transmission shall contain all the blocks of data associated with the parent SDU.

The ARQ feedback information can be sent as a standalone MAC management message on the appropriate basic management connection, or it can be piggybacked on an existing connection. ARQ feedback cannot be fragmented.

6.3.4.1 ARQ block usage

A MAC SDU is logically partitioned into blocks whose length is specified by the connection TLV parameter ARQ_BLOCK_SIZE. When the length of the SDU is not an integer multiple of the connection’s block size, the final block of the SDU is formed using the SDU bytes remaining after the final full block has been determined.

Once an SDU is partitioned into a set of blocks, that partitioning remains in effect until all blocks of the SDU are successfully delivered to the receiver, or the SDU is discarded by the transmitter state machine.

Sets of blocks selected for transmission or retransmission are encapsulated into a PDU. A PDU may contain blocks that are transmitted for the first time as well as those being retransmitted. Fragmentation shall occur only on ARQ block boundaries. If a PDU is not packed, all the blocks in that PDU shall have contiguous block numbers. When a PDU is packed, the sequence of blocks immediately between MAC subheaders and the sequence of blocks after the last PSH shall have contiguous block numbers.

If ARQ is enabled at the connection, FSH and PSH contain a BSN, which is the sequence number of the first ARQ block in the sequence of blocks following the subheader. It is a matter of transmitter policy whether a set of blocks once transmitted as a single PDU should be retransmitted also as a single PDU. Figure 48 illustrates the use of blocks for ARQ transmissions and retransmissions; two options for retransmission are presented—with and without rearrangements of blocks.
6.3.4.2 ARQ Feedback IE format

Table 169 defines the ARQ Feedback IE used by the receiver to signal positive or negative acknowledgments. A set of IEs of this format may be transported either as a packed payload ("piggybacked") within a packed MAC PDU or as a payload of a standalone MAC PDU.

**BSN**

If (ACK Type == 0x0): BSN value corresponds to the MSB of the first 16-bit ARQ ACK map and follows an MSB first approach with the BSN incremented by 1 for each bit in the ARQ ACK map, following through for the subsequent ARQ ACK maps.
If (ACK Type == 0x1): BSN value indicates that its corresponding block and all blocks with lesser (see 6.3.4.6.1) values within the transmission window have been successfully received.
If (ACK Type == 0x2): Combines the functionality of types 0x0 and 0x1.
If (ACK Type == 0x3): Combines the functionality of type 0x1 with the ability to acknowledge reception of ARQ blocks in terms of block sequences. A block sequence is defined as a set of ARQ blocks with consecutive BSN values. With this option, members of block sequences are identified and associated with the same reception status indication.

Selective ACK Map
Each bit set to one indicates the corresponding ARQ block has been received without errors. The bit corresponding to the BSN value in the IE, is the MSB of the first map entry. The bits for succeeding block numbers are assigned left-to-right (MSB to LSB) within the map entry. If the ACK Type is 0x2, then the MSB of the first map entry shall be set to one and the IE shall be interpreted as a cumulative ACK for the BSN value in the IE. The rest of the bitmap shall be interpreted similar to ACK Type 0x0.

Sequence ACK Map
Each bit set to one indicates the corresponding block sequence has been received without error. The MSB of the field corresponds to the first sequence length field in the descriptor. The bits for succeeding length fields are assigned left-to-right within the map entry.
Since the block sequence described by the first descriptor of the first map entry of the IE corresponds to the sequence of blocks immediately after the Cumulative ACK, the ACK map bit for this sequence shall be zero indicating this sequence has not yet been received.

Sequence Length
This value indicates the number of blocks that are members of the associated sequence. The BSN of the first block of the block sequence described by the first descriptor of the first IE map entry is the value of the Cumulative ACK plus one. The BSN of the first block of each block sequence is determined by adding the BSN of the first block of the previous block sequence to the length of that sequence. Within a map entry, Sequence Map/Length ordering follows the rule specified in the definition of Sequence ACK Map. Across map entries, ordering moves from the first map entry ($i = 0$) to the last map entry ($i = \text{Number of ACK Maps}$).

6.3.4.2.1 ARQ Feedback IE format with extended capability

Table 170 defines the ARQ Feedback IE used by the receiver to signal positive or negative Acknowledgments when the BS and MS use extended capability (11.7.8.11, bit 0 set to 1). A set of IEs of this format may be transported either as a packed payload (“piggybacked”) within a packed MAC PDU or as a payload of a standalone MAC PDU.

</table>
BSN

If the ACK Type is 0x0, the BSN value corresponds to the MSB of the first 16-bit ARQ ACK map and follows an MSB-first approach with the BSN incremented by 1 for each bit in the ARQ ACK map, following through for the subsequent ARQ ACK maps. If the ACK Type is 0x1, the BSN value indicates that its corresponding block and all blocks with lesser (see 6.3.4.6.1) values within the transmission window have been successfully received. If ACK Type == 0x2, the BSN combines the functionality of types 0x0 and 0x1. If the ACK Type is 0x3, the BSN combines the functionality of type 0x1 with the ability to acknowledge reception of ARQ blocks in terms of block sequences. A block sequence is defined as a set of ARQ blocks with consecutive BSN values. With this option, members of block sequences are identified and associated with the same reception status indication. If the ACK Type is 0x4, the BSN value corresponds to the first block of the first sequence of the first map. The block sequences are defined the same way as ACK type 0x3.

Selective ACK Map

Each following bit set to one indicates the corresponding ARQ block has been received without errors. The bit corresponding to the BSN value in the IE, is the MSB of the first map entry. The bits for succeeding block numbers are assigned left-to-right (MSB to LSB) within the map entry. If the ACK Type is 0x2, then the MSB of the first map entry represents the MAP Last field and the following shall be set to one and the IE shall be interpreted as a cumulative ACK for the BSN value in the IE. The rest of the bitmap shall be interpreted similarly to ACK Type 0x0.

Sequence ACK Map

Each bit set to one indicates that the corresponding block sequence has been received without error. The MSB of the field corresponds to the MAP Last field and the following corresponds to the first sequence length field in the descriptor. The bits for succeeding length fields are assigned left-to-right within the map entry. Since the block sequence described by the first descriptor of the first map entry of the IE corresponds to the sequence of blocks immediately after the Cumulative ACK, the ACK map bit for this sequence is omitted assuming a value of zero.

Each bit set to one indicates the corresponding block sequence has been received without error. The Sequence ACK Map of the first ACK Map of ACK type 0x3 is one bit or two bits long depending on the Sequence format. The most significant bit of the first ACK Map refers to the second sequence length.

The following ACK Maps, and maps of ACK type 0x4, are two bits or three bits long, depending on the Sequence Format. The MSB of the field corresponds to the first sequence length field in the descriptor.

The bits for succeeding length fields are assigned left-to-right within the map entry.
Sequence Length
This value indicates the number of blocks that are members of the associated sequence. The BSN of the first block of the block sequence described by the first descriptor of the first IE map entry is the value of the Cumulative ACK plus one. The BSN of the first block of each block sequence is determined by adding the BSN of the first block of the previous block sequence to the length of that sequence. Within a map entry, Sequence Map/Length ordering follows the rule specified in the definition of Sequence ACK Map. Across map entries, ordering moves from the first map entry \((i = 0)\) to the last map entry \((i = \text{Number of ACK Maps})\).

6.3.4.3 ARQ parameters

6.3.4.3.1 ARQ_BSN_MODULUS

\(ARQ\_BSN\_MODULUS\) is equal to the number of unique BSN values, i.e., \(2^{11}\).

6.3.4.3.2 ARQ_WINDOW_SIZE

\(ARQ\_WINDOW\_SIZE\) is the maximum number of ARQ blocks with consecutive BSN in the sliding window of ARQ blocks that is managed by the receiver and the transmitter.

\(ARQ\_WINDOW\_SIZE\) shall be less than or equal to half of the \(ARQ\_BSN\_MODULUS\).

6.3.4.3.3 ARQ_BLOCK_LIFETIME

\(ARQ\_BLOCK\_LIFETIME\) is the maximum time interval an ARQ block shall be managed by the transmitter ARQ state machine, once initial transmission of the block has occurred. If transmission (or subsequent retransmission) of the block is not acknowledged by the receiver before the time limit is reached, the block is discarded. The start of the block’s lifetime shall be the frame in which the block was first transmitted.

6.3.4.3.4 ARQ_RETRY_TIMEOUT

ARQ_RETRY_TIMEOUT is the minimum time interval a transmitter shall wait before retransmission of an unacknowledged block for retransmission. The interval begins when the ARQ block was last transmitted. On connections that use both HARQ and ARQ, the ARQ_RETRY_TIMEOUT value shall be set accordingly to allow HARQ retransmission operation of the ARQ block to be completed before ARQ retransmission occurs. An ARQ block is unacknowledged if it has been transmitted but no acknowledgment has been received.

6.3.4.3.5 ARQ_SYNC_LOSS_TIMEOUT

\(ARQ\_SYNC\_LOSS\_TIMEOUT\) is the maximum time interval \(ARQ\_TX\_WINDOW\_START\) or \(ARQ\_RX\_WINDOW\_START\) shall be allowed to remain at the same value before declaring a loss of synchronization of the sender and receiver state machines when data transfer is known to be active. The ARQ receiver and transmitter state machines manage independent timers. Each has its own criteria for determining when data transfer is “active” (see 6.3.4.6.2 and 6.3.4.6.3).

6.3.4.3.6 ARQ_RX_PURGE_TIMEOUT

\(ARQ\_RX\_PURGE\_TIMEOUT\) is the time interval the receiver shall wait after successful reception of a block that does not result in advancement of \(ARQ\_RX\_WINDOW\_START\), before advancing \(ARQ\_RX\_WINDOW\_START\) (see 6.3.4.6.3).
6.3.4.3.7 ARQ_BLOCK_SIZE

ARQ_BLOCK_SIZE is the length used for partitioning an SDU into a sequence of ARQ blocks prior to transmission (see 6.3.4.1)

6.3.4.4 ARQ procedures

6.3.4.4.1 ARQ state machine variables

All ARQ state machine variables are set to 0 at connection creation or by an ARQ reset operation.

6.3.4.4.1.1 Transmitter variables

ARQ_TX_WINDOW_START: All BSN up to (ARQ_TX_WINDOW_START – 1) have been acknowledged.

ARQ_TX_NEXT_BSN: BSN of the next block to send. This value shall reside in the interval ARQ_TX_WINDOW_START to (ARQ_TX_WINDOW_START + ARQ_WINDOW_SIZE), inclusive.

6.3.4.4.1.2 Receiver variables

ARQ_RX_WINDOW_START: All BSN up to (ARQ_RX_WINDOW_START – 1) have been correctly received.

ARQ_RX_HIGHEST_BSN: BSN of the highest block received, plus one. This value shall reside in the interval ARQ_RX_WINDOW_START to (ARQ_RX_WINDOW_START + ARQ_WINDOW_SIZE), inclusive.

6.3.4.5 ARQ-enabled connection setup and negotiation

Connections are set up and defined dynamically through the DSA/DSC class of messages. CRC-32 shall be used for error detection of PDUs for all ARQ-enabled connections. All the ARQ parameters (see 6.3.4.3) shall be set when an ARQ-enabled connection is set up. The transmitter and receiver variables (defined in 6.3.4.4.1) shall be reset on connection setup.

6.3.4.6 ARQ operation

6.3.4.6.1 Sequence number comparison

Transmitter and receiver state machine operations include comparing BSNs and taking actions based on which is larger or smaller. In this context, it is not possible to compare the numeric sequence number values directly to make this determination. Instead, the comparison shall be made by normalizing the values relative to the appropriate state machine base value and the maximum value of sequence numbers, ARQ_BSN_MODULUS, and then comparing the normalized values. Normalization is accomplished by using Equation (1).

\[
bsn' = (bsn – BSN_{\text{base}}) \mod ARQ_BSN_{\text{MODULUS}}
\]

(1)

The base values for the receiver and transmitter state machines are ARQ_TX_WINDOW_START and ARQ_RX_WINDOW_START, respectively.
6.3.4.6.2 Transmitter state machine

An ARQ block may be in one of the following four states—not-sent, outstanding, discarded, and waiting-for-retransmission. Any ARQ block begins as not-sent. After it is sent it becomes outstanding for a period of time termed `ARQ_RETRY_TIMEOUT`. While a block is in outstanding state, it is either acknowledged and discarded, or transitions to waiting-for-retransmission after `ARQ_RETRY_TIMEOUT` or NACK. An ARQ block can become waiting-for-retransmission before the `ARQ_RETRY_TIMEOUT` period expires if it is negatively acknowledged. An ARQ block may also change from waiting-for-retransmission to discarded when an ACK message for it is received or after a timeout `ARQ_BLOCK_LIFETIME`.

For a given connection the transmitter shall first handle (transmit or discard) blocks in “waiting-for-retransmission” state and only then blocks in “not-sent” state. Blocks in “outstanding” or “discarded” state shall not be transmitted. When blocks are retransmitted, the block with the lowest BSN shall be retransmitted first.

The ARQ Tx block state sequence is shown in Figure 49.

![Figure 49—ARQ Tx block states](image)

MAC PDU formation continues with a connection’s “not-sent” MAC SDUs. The transmitter builds each MAC PDU using the rules for fragmentation and packing as long as the number of blocks to be sent plus the number of block already transmitted and awaiting retransmission does not exceed the limit imposed by `ARQ_WINDOW_SIZE`. As each “not-sent” block is formed and included in a MAC PDU, it is assigned the current value of `ARQ_TX_NEXT_BSN`, which is then incremented.

When a Cumulative ACK acknowledgment is received, the transmitter shall check the validity of the BSN. A valid BSN is one in the interval `ARQ_TX_WINDOW_START` to `ARQ_TX_NEXT_BSN – 1` (inclusive). If BSN is not valid, the transmitter shall ignore the acknowledgment.

When a Selective ACK, Cumulative+Selective ACI or Cumulative ACK with Block Sequence acknowledgement is received, the transmitter shall check the validity of each block described in the message. The acknowledgement of a block is valid if its corresponding block number lies in the interval `ARQ_TX_WINDOW_START` to `ARQ_TX_NEXT_BSN-1` (inclusive). If the block number lies outside this interval, the transmitter shall ignore the acknowledgement of that block.

When a cumulative acknowledgment with a valid BSN is received, the transmitter shall consider all blocks in the interval `ARQ_TX_WINDOW_START` to BSN (inclusive) as acknowledged and set `ARQ_TX_WINDOW_START` to BSN + 1.
When a selective acknowledgment is received, the transmitter shall consider as acknowledged all blocks so indicated by the entries in the bitmap for valid BSN values. As the bitmap entries are processed in increasing BSN order, ARQ_TX_WINDOW_START shall be incremented each time the BSN of an acknowledged block is equal to the value of ARQ_TX_WINDOW_START.

When ARQ_TX_WINDOW_START has been advanced by either of the above methods and acknowledgment of reception has already been received for the block with the BSN value now assigned to ARQ_TX_WINDOW_START, the value of ARQ_TX_WINDOW_START shall be incremented until a BSN value is reached for which no acknowledgment has been received.

A bitmap entry not indicating acknowledgement shall be considered a NACK for the corresponding blocks.

NOTE—Selective ACK bit-maps are referenced to a specific BSN, which indicates to absolute number of the block referenced by the first bit in the bit-map. It is the responsibility of the ARQ feedback sender to assign the BSN so that all bits in the bitmap define either ACK or NAK for a specific ARQ block. This can be achieved by assigning the BSN low enough (modulo $2^{11}$) so that every bit in the bit map provides correct feedback information.

When a cumulative with selective acknowledgment and a valid BSN is received, the transmitter performs the actions described above for cumulative acknowledgment, followed by those for a selective acknowledgment.

All timers associated with acknowledged blocks shall be cancelled.

A Discard message shall be sent following violation of ARQ_BLOCK_LIFETIME. The message may be sent immediately or may be delayed up to ARQ_RX_PURGE_TIMEOUT + ARQ_RETRY_TIMEOUT. If ARQ_RX_PURGE_TIMEOUT is infinite (i.e., has value zero) then the message may be delayed up to ARQ_RETRY_TIMEOUT. Following the first transmission, subsequent discard orders shall be sent to the receiver at intervals of ARQ_RETRY_TIMEOUT until an acknowledgment to the discarded BSN has been received. Discard orders for adjacent BSN values may be accumulated in a single Discard message.

The actions to be taken by the transmitter state machine when it wants to initiate a reset of the receiver ARQ state machine are provided in Figure 50. The actions to be taken by the receiver state machine when it initiates an ARQ Reset message are provided in Figure 51.
Figure 50—ARQ Reset message dialog—Transmitter-initiated
Figure 51—ARQ Reset message dialog—Receiver-initiated
Synchronization of the ARQ state machines is governed by a timer managed by the transmitter state machine. Each time $ARQ_{TX\_WINDOW\_START}$ is updated, the timer is set to zero. When the timer exceeds the value of $ARQ\_SYNC\_LOSS\_TIMEOUT$, the transmitter state machine shall initiate a reset of the connection’s state machines as described in Figure 50.

When in ARQ reset error state in Figure 50 and Figure 51, the SS shall reinitialize its MAC, and the behavior for BS is implementation dependent.

A Discard message may be sent to the receiver when the transmitter wants to skip ARQ blocks up to the BSN value specified in the Discard message. Upon receipt of the message, the receiver updates its state information to indicate the specified blocks were received and forwards the information to the transmitter through an ARQ Feedback IE at the appropriate time.

### 6.3.4.6.3 Receiver state machine

When a PDU is received, its integrity is determined based on the CRC-32 checksum. If a PDU passes the checksum, it is unpacked and defragmented, if necessary. The receiver maintains a sliding-window defined by $ARQ\_RX\_WINDOW\_START$ state variable and the $ARQ\_WINDOW\_SIZE$ parameter. When an ARQ block with a number that falls in the range defined by the sliding window is received, the receiver shall accept it. ARQ block numbers outside the sliding window shall be rejected as out of order. The receiver should discard duplicate ARQ blocks (i.e., ARQ blocks that where already received correctly) within the window. See Figure 52.

![Figure 52—ARQ block reception](image-url)
The sliding window is maintained so that the `ARQ_RX_WINDOW_START` variable always points to the lowest numbered ARQ block that has not been received or has been received with errors. When an ARQ block with a number corresponding to the `ARQ_RX_WINDOW_START` is received, the window is advanced (i.e., `ARQ_RX_WINDOW_START` is incremented modulo `ARQ_BSN_MODULUS`) so that the `ARQ_RX_WINDOW_START` variable points to the next lowest numbered ARQ block that has not been received or has been received with errors. The timer associated with `ARQ_SYNC_LOSS_TIMEOUT` shall be reset.

When a block does not result in an advance of the `ARQ_RX_WINDOW_START`, the ARQ_RX_PURGE_TIMEOUT for that block shall be started. When the value of the timer for a block exceeds `ARQ_RX_PURGE_TIMEOUT`, the timeout condition is marked. When the timeout condition is marked, `ARQ_RX_WINDOW_START` is advanced to the BSN of the next block not yet received after the marked block. Timers for delivered blocks remain active and are monitored for timeout until the BSN values are outside the receive window.

When `ARQ_RX_WINDOW_START` is advanced, any BSN values corresponding to blocks that have not yet been received residing in the interval between the previous and current `ARQ_RX_WINDOW_START` value shall be marked as received and the receiver shall send an ARQ Feedback IE to the transmitter with the updated information. Any blocks belonging to complete SDUs shall be delivered. Blocks from partial SDUs shall be discarded.

When a discard message is received from the transmitter, the receiver shall discard the specified blocks, advance `ARQ_RX_WINDOW_START` to the BSN of the first block not yet received after the BSN provided in the Discard message, and mark all not received blocks in the interval from the previous to new `ARQ_RX_WINDOW_START` values as received for ARQ Feedback IE reporting.

For each ARQ block received, an acknowledgment shall be sent to the transmitter. Acknowledgment for blocks outside the sliding window shall be cumulative. Acknowledgments for blocks within the sliding window may be either for specific ARQ blocks (i.e., contain information on the acknowledged ARQ block numbers), or cumulative (i.e., contain the highest ARQ block number below which all ARQ blocks have been received correctly) or a combination of both (i.e., cumulative with selective). Acknowledgments shall be sent in the order of the ARQ block numbers they acknowledge. The frequency of acknowledgment generation is not specified here and is implementation dependent.

A MAC SDU is ready to be handed to the upper layers when all of the ARQ blocks of the MAC SDU have been correctly received within the time-out values defined.

When `ARQ_DELIVER_IN_ORDER` is enabled, a MAC SDU is handed to the upper layers as soon as all the ARQ blocks of the MAC SDU have been correctly received within the defined time-out values and all blocks with sequence numbers smaller than those of the completed message have either been discarded due to time-out violation or delivered to the upper layers.

When `ARQ_DELIVER_IN_ORDER` is not enabled, MAC SDUs are handed to the upper layers as soon as all blocks of the MAC SDU have been successfully received within the defined time-out values.

The actions to be taken by the receiver state machine when an ARQ Reset message is received are provided in Figure 50. The actions to be taken by the receiver state machine when it wants to initiate a reset of the transmitter ARQ state machine are provided in Figure 51.

Synchronization of the ARQ state machines is governed by a timer managed by the receiver state machine. Each time `ARQ_RX_WINDOW_START` is updated, the timer is set to zero. When the timer exceeds the value of `ARQ_SYNC_LOSS_TIMEOUT`, the receiver state machine shall initiate a reset of the connection’s state machines as described in Figure 51.
6.3.5 Scheduling services

Scheduling services represent the data handling mechanisms supported by the MAC scheduler for data transport on a connection. Each connection is associated with a single scheduling service. A scheduling service is determined by a set of QoS parameters that quantify aspects of its behavior. These parameters are managed using the DSA and DSC message dialogs. A detailed description of each QoS parameter is provided in 11.13.

Well-known scheduling services can be implemented by specifying a specific set of QoS parameters.

Table 171 describes the QoS parameters that would provide a scheduling service to support real-time data streams consisting of fixed-size data packets issued at periodic intervals, such as T1/E1 and Voice over IP without silence suppression.

Table 171—Example of QoS parameters providing scheduling service to support real-time constant bit-rate data streams

Table 174 describes the QoS parameters that would provide a scheduling service to support data streams for which no minimum service level is required and therefore may be handled on a space-available basis.
6.3.5.1 Outbound transmission scheduling

Outbound transmission scheduling selects the data for transmission in a particular frame/bandwidth allocation and is performed by the BS for DL, and SS for UL. In addition to whatever other factors the scheduler may deem pertinent, the following items are taken into account for each active service flow:

- The scheduling service specified for the service flow.
- The values assigned to the service flow’s QoS parameters.
- The availability of data for transmission.
- The capacity of the granted bandwidth.

6.3.5.2 UL request/grant scheduling

UL request/grant scheduling is performed by the BS with the intent of providing each subordinate SS with bandwidth for UL transmissions or opportunities to request bandwidth. By specifying a scheduling type and its associated QoS parameters, the BS scheduler can anticipate the throughput and latency needs of the UL traffic and provide polls and/or grants at the appropriate times.

Table 175 summarizes the scheduling types and the poll/grant options available for each. The service flow scheduling services for UL operations are defined in 6.3.5.2.1 through 6.3.5.2.4.

6.3.5.2.1 Unsolicited grant service (UGS)

The UGS is designed to support real-time uplink service flows that transport fixed-size data packets on a periodic basis, such as T1/E1 and Voice over IP without silence suppression. The service offers fixed-size grants on a real-time periodic basis, which eliminate the overhead and latency of SS requests and assure that grants are available to meet the flow’s real-time needs. The BS shall provide Data Grant Burst IEs to the SS at periodic intervals based upon the Minimum Reserved Traffic Rate of the service flow. The size of these grants shall be sufficient to hold the fixed-length data associated with the service flow (with associated generic MAC header and GMSH) but may be larger at the discretion of the BS scheduler. In order for this service to work correctly, the Request/Transmission Policy (see 11.13.11) setting shall be such that the SS is prohibited from using any contention request opportunities for this connection. The mandatory QoS parameters are Minimum Reserved Traffic Rate (11.13.8), Maximum Latency (11.13.13), Tolerated Jitter (11.13.12), Uplink Grant Scheduling Type (11.13.10), SDU size (for fixed length SDU service flows) (11.13.15), Request/Transmission Policy (11.13.11), and Unsolicited Grant Interval (11.13.19). If present, the Minimum Reserved Traffic Rate parameter (11.13.8) shall have the same value as the Maximum Sustained Traffic Rate parameter.
The GMSH (6.3.2.2.2) is used to pass status information from the SS to the BS regarding the state of the UGS service flow. The MSB of the Grant Management field is the SI (slip indicator) bit. The SS shall set this flag once it detects that this service flow has exceeded its Tx queue depth. Once the SS detects that the service flow’s Tx queue is back within limits, it shall clear the SI flag. The flag allows the BS to provide for long term compensation for conditions, such as lost maps or clock rate mismatches, by issuing additional grants. The poll-me (PM) bit (6.3.6.3.3) may be used to request to be polled for a different, non-UGS connection.

The BS shall not allocate more bandwidth than the Minimum Reserved Traffic Rate parameter of the active QoS parameter set, excluding the case when the SI bit of the Grant Management field is set. In this case, the BS may grant up to 1% additional bandwidth for clock rate mismatch compensation.

The FL (frame latency) and FLI (frame latency indication) fields may be used to provide the BS with information on the synchronization of the MS application that is generating periodic data for UGS/Extended rtPS service flows.

The MS may use these fields to detect whether latency experienced by this service flow at the MS exceeds a certain limit, e.g., a single frame duration. If the FL indicates inordinate latency, the BS may shift scheduled grants earlier for this service flow (taking into account the Frame Latency, FL).

### 6.3.5.2.2 Real-time polling service (rtPS)

The rtPS is designed to support real-time UL service flows that transport variable-size data packets on a periodic basis, such as moving pictures experts group (MPEG) video. The service offers real-time, periodic, unicast request opportunities, which meet the flow’s real-time needs and allow the SS to specify the size of the desired grant. This service requires more request overhead than UGS, but supports variable grant sizes for optimum data transport efficiency.

The BS shall provide periodic unicast request opportunities. In order for this service to work correctly, the Request/Transmission Policy setting (see 11.13.11) shall be such that the SS is prohibited from using any contention request opportunities for that connection. The BS may issue unicast request opportunities as prescribed by this service even if prior requests are currently unfulfilled. This results in the SS using only unicast request opportunities and data transmission opportunities in order to obtain UL transmission opportunities. All other bits of the Request/Transmission Policy are irrelevant to the fundamental operation of this scheduling service and should be set according to network policy. The mandatory QoS parameters are Minimum Reserved Traffic Rate (11.13.8), Maximum Sustained Traffic Rate (11.13.6), Maximum Latency (11.13.13), Uplink Grant Scheduling Type (11.13.10), Request/Transmission Policy (11.13.11) and Unsolicited Polling Interval (11.13.20).

### 6.3.5.2.2.1 Extended rtPS

Extended rtPS is a scheduling mechanism which builds on the efficiency of both UGS and rtPS. The BS shall provide unicast grants in an unsolicited manner like in UGS, thus saving the latency of a BR. However, whereas UGS allocations are fixed in size, erTPS allocations are dynamic.

The BS may provide periodic UL allocations that may be used for requesting the bandwidth as well as for data transfer. By default, size of allocations corresponds to current value of Maximum Sustained Traffic Rate at the connection. The MS may request changing the size of the UL allocation either by using an Extended Piggyback Request field of the GMSH or the BR field of the MAC signaling headers as described in Table 7 or by sending a codeword (defined in 8.4.11.13) over CQICH. The BS shall not change the size of UL allocations until receiving another bandwidth change request from the MS. When the BR size is set to zero, the BS may provide allocations for only BR header or no allocations at all. In case that no unicast BR opportunities are available, the MS may use contention request opportunities for that connection, or send the CQICH codeword to inform the BS of its having the data to send. If the BS receives the CQICH codeword,
the BS shall start allocating the UL grant corresponding to the current Maximum Sustained Traffic Rate value.

The mandatory QoS parameters are the Maximum Sustained Traffic Rate, the Minimum Reserved Traffic Rate, the Maximum Latency, the Request/Transmission Policy and Unsolicited Grant Interval (11.13.19).

The Extended rtPS is designed to support real-time service flows that generate variable-size data packets on a periodic basis, such as Voice over IP services with silence suppression.

### 6.3.5.2.3 Non-real-time polling service (nrtPS)

The nrtPS offers unicast polls on a regular basis, which assures that the UL service flow receives request opportunities even during network congestion. The BS typically polls nrtPS connections on an interval on the order of one second or less.

The BS shall provide timely unicast request opportunities. In order for this service to work correctly, the Request/Transmission Policy setting (see 11.13.11) shall be such that the SS is allowed to use contention request opportunities. This results in the SS using contention request opportunities as well as unicast request opportunities and data transmission opportunities. All other bits of the Request/Transmission Policy are irrelevant to the fundamental operation of this scheduling service and should be set according to network policy. The mandatory QoS parameters for this scheduling service are Minimum Reserved Traffic Rate (11.13.8), Maximum Sustained Traffic Rate (11.13.6), Traffic Priority (11.13.5), Uplink Grant Scheduling Type (11.13.10), and Request/Transmission Policy (11.13.11).

### 6.3.5.2.4 Best effort (BE) service

The intent of the BE grant scheduling type is to provide efficient service for BE traffic in the UL. In order for this service to work correctly, the Request/Transmission Policy setting shall be set so that the SS is allowed to use contention request opportunities. This results in the SS using contention request opportunities as well as unicast request opportunities and data transmission opportunities. All other bits of the Request/Transmission Policy are irrelevant to the fundamental operation of this scheduling service and should be set according to network policy.

### 6.3.6 Bandwidth allocation and request mechanisms

Note that during network entry and initialization every SS is assigned up to three dedicated CIDs for the purpose of sending and receiving management messages. These connection pairs are used to allow differentiated levels of QoS to be applied to the different connections carrying MAC management traffic. Increasing (or decreasing) bandwidth requirements is necessary for all services except UGS connections. The needs of UGS connections do not change between connection establishment and termination.

When an SS needs to ask for bandwidth on a connection with BE scheduling service, it sends a message to the BS containing the immediate requirements of the connection. QoS for the connection was established at the connection setup and is looked up by the BS.

### 6.3.6.1 Requests

Requests refer to the mechanism that SSs use to indicate to the BS that they need UL bandwidth allocation. A Request may come as a stand-alone BR header or it may come as a PiggyBack Request (e.g., Grant management subheader, see 6.3.2.2.2). The use of Grant management subheader is optional.

Because the UL burst profile can change dynamically, all requests for bandwidth shall be made in terms of the number of bytes needed to carry the MAC PDU excluding PHY overhead. The BR message may be
transmitted during any UL allocation, except during any initial ranging interval. An SS shall not request bandwidth for a connection if it has no PDU to transmit on that connection.

BRs may be incremental or aggregate. When the BS receives an incremental BR, it shall add the quantity of bandwidth requested to its current perception of the bandwidth needs of the connection. When the BS receives an aggregate BR, it shall replace its perception of the bandwidth needs of the connection with the quantity of bandwidth requested. The Type field in the BR header indicates whether the request is incremental or aggregate. Since Piggybacked BRs do not have a type field, Piggybacked BRs shall always be incremental. The self-correcting nature of the request/grant protocol requires that SSs may periodically use aggregate BRs as a function of the QoS of a service and of the link quality. Due to the possibility of collisions, contention-based BRs shall be aggregate requests except in the OFDMA PHY. In the OFDMA PHY, the SS may respond to the CDMA Allocation IE with either aggregate or incremental BR.

Additional BR mechanisms include the focused BRs (see 6.3.6.4) and CDMA BRs (see 6.3.6.5).

Capability of incremental BRs is optional for the SS and mandatory for the BS. Capability of aggregate BRs is mandatory for SS and BS.

In OFDMA, the bandwidth request is to be interpreted by the BS as the amount of data that the SS requires for a connection after the SS has sent the data that is in the current burst.

### 6.3.6.2 Grants

For an SS, BRs reference individual connections while each unicast bandwidth grant is addressed to the SS’s Basic CID, not to individual CIDs. Since it is nondeterministic which request is being honored, when the SS receives a shorter transmission opportunity than expected (scheduler decision, request message lost, etc.), no explicit reason is given. In all cases, based on the latest information received from the BS and the status of the request, the SS may decide to perform backoff and send a new request.

For the SC and OFDM PHY, an SS may use multicast or broadcast grants to transmit a bandwidth request.

### 6.3.6.3 Polling

To poll an SS, the BS allocates, in the UL-MAP, bandwidth sufficient to respond with a BR. These allocations may be to individual SSs (all PHYs) or to groups of SSs (OFDM and SC only). The allocations are contained as a series of IEs within the UL-MAP.

Note that polling is done on SS basis. Bandwidth is always requested on a CID basis and bandwidth is allocated on an SS basis.

### 6.3.6.3.1 Unicast polling

When an SS is polled individually, the BS allocates, in the UL-MAP, sufficient bandwidth for the SS to respond with a BR. If the SS does not need bandwidth, the allocation may be padded in accordance with 6.3.3.7 else the SS may transmit a request for zero bandwidth. SSs that have an active UGS connection shall not be polled individually unless they set the PM bit in the GMSH of a MAC PDU on the UGS connection. This saves bandwidth over repetitive polling of the SSs.
The information exchange sequence for individual polling is shown in Figure 53.
6.3.6.3.2 Multicast and broadcast polling

This subclause applies to the SC and OFDM PHY.

If insufficient bandwidth is available to individually poll many inactive SSs, some SSs may be polled in multicast groups or a broadcast poll may be issued. Certain CIDs are reserved for multicast groups and for broadcast messages, as described in Table 558. As with individual polling, the poll is not an explicit message, but bandwidth allocated in the UL-MAP. The difference is that, rather than associating allocated bandwidth with an SS's Basic CID, the allocation is to a multicast or Broadcast CID. An example is provided in Table 176.

Table 176—Sample UL-MAP with multicast and broadcast IE for SC

<table>
<thead>
<tr>
<th>Interval description</th>
<th>UL-MAP IE fields</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CID (16 bits)</td>
</tr>
<tr>
<td>Initial ranging</td>

</tr>
<tr>
<td>SS 21 UL grant</td>
<td>0x01C9</td>
</tr>
</tbody>
</table>
The information exchange sequence for multicast and broadcast polling is shown in Figure 54.

When the poll is directed at a multicast or Broadcast CID, an SS belonging to the polled group may request bandwidth during any request interval allocated to that CID in the UL-MAP by a Request IE. In order to reduce the likelihood of collision with multicast and broadcast polling, only SS’s needing bandwidth reply; they shall apply the contention resolution algorithm as defined in 6.3.8 to select the slot in which to transmit the initial BR. Zero-length BRs shall not be used in multicast or broadcast request intervals.

The SS shall assume that the transmission has been unsuccessful if no grant has been received in the number of subsequent UL-MAP messages specified by the parameter Contention-based reservation timeout (see Figure 54—Multicast and broadcast polling).
11.3.1). Note that, with a frame-based PHY with UL-MAPs occurring at predetermined instants, erroneous UL-MAPs may be counted towards this number. If the rerequest is made in a multicast or broadcast opportunity, the SS continues to run the contention resolution algorithm in 6.3.8. Note that the SS is not restricted to issuing the rerequest in a multicast or broadcast request interval.

**6.3.6.3.3 PM bit**

SSs with currently active UGS connections may set the PM bit [bit PM in the GMSH (6.3.2.2.2)] in a MAC packet of the UGS connection to indicate to the BS that they need to be polled to request bandwidth for non-UGS connections. To reduce the bandwidth requirements of individual polling, SSs with active UGS connections need be individually polled only if the PM bit is set (or if the interval of the UGS is too long to satisfy the QoS of the SS’s other connections). Once the BS detects this request for polling, the process for individual polling is used to satisfy the request. The procedure by which an SS stimulates the BS to poll it is shown in Figure 55. To minimize the risk of the BS missing the PM bit, the SS may set the bit in all UGS MAC GMSHs in the UL scheduling interval.

![PM bit usage diagram](image)

**Figure 55—PM bit usage**

**6.3.6.4 Contention-based focused BRs for WirelessMAN-OFDM**

The WirelessMAN-OFDM PHY supports two contention-based BR mechanisms. The mandatory mechanism allows the SS to send the BR header as specified in 6.3.6.1 during a REQ Region-Full. Alternatively, the SS may send a Focused Contention Transmission during a REQ Region-Focused. This transmission consists of a contention code modulated on a contention channel consisting of four carriers. The selection of the contention code is done with equal probability among the eight possible codes. The selection of the contention channel is done with equal probability among the time/frequency Tx opportunities applicable to the SS. Upon detection, the BS shall provide an UL allocation for the SS to transmit a BR MAC PDU and optionally additional data, but instead of indicating a Basic CID, the Broadcast CID shall be sent in combination with an OFDM Focused Contention IE, which specifies the contention channel, contention code, and Tx opportunity that were used by the SS. This allows an SS to determine whether it has been given an allocation by matching these parameters with the parameters it used. See also 8.3.7.3.3.
6.3.6.5 Contention-based CDMA BRs for WirelessMAN-OFDMA

The WirelessMAN-OFDMA PHY supports two mandatory BR mechanisms: the SS shall either send the BR header as specified in 6.3.6.1, or use the CDMA-based contention mechanism as specified in the following paragraphs of this subclause.

As specified in 6.3.10.3, the OFDMA PHY specifies a ranging subchannel and a subset of ranging codes that shall be used for contention-based BRs. The SS, upon needing to request bandwidth, shall select, with equal probability, a ranging code from the code subset allocated to BRs. This ranging code shall be modulated onto the ranging subchannel and transmitted during a Ranging Slot randomly selected from the appropriate ranging region in a single frame.

Upon detection, the BS shall provide an UL allocation for the SS using Broadcast CID in combination with a CDMA Allocation IE, which specifies the Tx region and ranging code that were used by the SS for transmission of the CDMA code. This allows an SS to determine whether it has been given an allocation by matching these parameters with the parameters it used. The SS shall use the allocation to transmit a Bandwidth request header or another header containing a BR field except when the BS indicated the header can be omitted in the CDMA Allocation IE (see Table 379). The SS may also transmit data in this allocation.

If the BS does not issue the CDMA allocation IE as described above, or the BR MAC PDU does not result in a subsequent allocation of any bandwidth, the SS shall assume that the ranging code transmission resulted in a collision and follow the contention resolution as specified in 6.3.8.

6.3.7 MAC support of PHY

Several duplexing techniques are supported by the MAC protocol. The choice of duplexing technique may affect certain PHY parameters as well as impact the features that can be supported.

6.3.7.1 Frequency division duplexing (FDD)

In an FDD system, the UL and DL channels are located on separate frequencies and the DL data can be transmitted in bursts. A fixed duration frame is used for both UL and DL transmissions. This facilitates the use of different modulation types. It also allows simultaneous use of both full-duplex SSs (which can transmit and receive simultaneously) and optionally half-duplex SSs (which cannot). If half-duplex SSs are used, the bandwidth controller shall not allocate UL bandwidth for a half-duplex SS at the same time that it is expected to receive data on the DL channel, including allowance for the propagation delay, SS transmit/receive transition gap (SSTTG) and SS receive/transmit transition gap (SSRTG).

Figure 56 describes the basics of the FDD mode of operation. The fact that the UL and DL channels utilize a fixed duration frame simplifies the bandwidth allocation algorithms. A full-duplex SS is capable of continuously listening to the DL channel, while a half-duplex SS can listen to the DL channel only when it is not transmitting in the UL channel.

6.3.7.2 Time division duplexing (TDD)

In the case of TDD, the UL and DL transmissions occur at different times and usually share the same frequency. A TDD frame (see Figure 57) has a fixed duration and contains one DL and one UL subframe. The frame is divided into an integer number of PSs, which help to partition the bandwidth easily. The TDD framing is adaptive in that the bandwidth allocated to the DL versus the UL can vary. The split between UL and DL is a system parameter and is controlled at higher layers within the system.

6.3.7.3 DL-MAP message

The DL-MAP message defines the usage of the DL intervals for a burst mode PHY.
6.3.7.4 UL-MAP message

The UL-MAP message defines the UL usage in terms of the offset of the burst relative to the Allocation Start Time (units PHY-specific).
6.3.7.4.1 UL timing

UL timing is referenced from the beginning of the DL subframe. The Allocation Start Time in the UL-MAP is referenced from the start of the DL subframe and may be such that the UL-MAP references some point in the current or a future frame (see 6.3.7.5). The SS shall always adjust its concept of UL timing based upon the Timing Adjustments sent in the RNG-RSP messages.

6.3.7.4.2 UL allocations

For the SC PHY, the UL bandwidth allocation map (UL-MAP) uses units of minislots. The size of the minislot is specified as a function of PSs and is carried in the UCD for each UL channel.

For the OFDM and OFDMA PHYS, the UL bandwidth allocation map (UL-MAP) uses units of symbols and subchannels.

6.3.7.4.3 UL interval definition

All of the IEs defined in 6.3.7.4.3.1 through 6.3.7.4.3.5 shall be supported by conformant SSs. Conformant BS may use any of these IEs when creating a UL-MAP message.

6.3.7.4.3.1 Request IE

Via the Request IE, the BS specifies an UL interval in which requests may be made for bandwidth for UL data transmission. The character of this IE changes depending on the type of CID used in the IE. If broadcast or multicast, this is an invitation for SSs to contend for requests. If unicast, this is an invitation for a particular SS to request bandwidth. Unicasts may be used as part of a QoS scheduling scheme that is vendor dependent. For any UL allocation, the SS may optionally decide to use the allocation for data or requests (or requests piggybacked in data). PDUs transmitted in this interval shall use the BR header format (see 6.3.2).

For BR contention opportunities, the BS shall allocate a grant that is an integer multiple of the value of “Bandwidth request opportunity size,” which shall be published in each UCD transmission.

This subclause does not apply to the OFDMA PHY.

6.3.7.4.3.2 Initial Ranging IE

Via the Initial Ranging IE, the BS specifies an interval in which new stations may join the network. An interval, equivalent to the maximum round-trip propagation delay plus the transmission time of the RNG-REQ message, shall be provided in some UL-MAPs to allow new stations to perform initial ranging. Packets transmitted in this interval shall use the RNG-REQ MAC management message format (see 6.3.2.3.5).

For ranging contention opportunities, the BS shall allocate a grant that is an integer multiple of the value of “Ranging request opportunity size,” which shall be published in each UCD transmission.

This subclause does not apply to the OFDMA PHY, in which CDMA-based ranging is used, as described in 6.3.10.3.

6.3.7.4.3.3 Data Grant Burst Type IEs

The Data Grant Burst Type IEs provide an opportunity for an SS to transmit one or more UL PDUs. These IEs are issued either in response to a request from a station, or because of an administrative policy, such as unicast polling, providing some amount of bandwidth to a particular station.
The number of Data Grant Burst Types available is PHY-specific. Each Data Grant Burst Type description is defined in the UCD message.

6.3.7.4.3.4 End Of Map IE

An End Of Map IE terminates all actual allocations in the IE list. It is used to determine the length of the last interval.

This IE is not used in OFDMA PHY.

6.3.7.4.3.5 Gap IE

The Gap IE indicates pauses in UL transmissions. An SS shall not transmit during a Gap IE.

6.3.7.5 Map relevance and synchronization

Timing information in the DL-MAP and UL-MAP is relative. The following time instants are used as a reference for timing information:

— DL-MAP: The start of the first symbol (including the preamble if present) of the frame in which the message was transmitted.
— UL-MAP: The start of the first symbol (including the preamble if present) of the frame in which the message was transmitted plus the value of the Allocation Start Time.

Information in the DL-MAP pertains to the current frame (the frame in which the message was received). Information carried in the UL-MAP pertains to a time interval starting at the Allocation Start Time measured from the beginning of the current frame and ending after the last specified allocation. For the OFDM PHY with an UL-MAP sent in AAS zone, the allocation start time shall be measured from the start of the AAS zone in which the UL MAP was sent. This timing holds for both the TDD and FDD variants of operation. The TDD variant is shown in Figure 58 and Figure 59. The FDD variant is shown in Figure 60 and Figure 61.

![Figure 58—Maximum time relevance of DL-MAP and UL-MAP (TDD)]
Figure 59—Minimum time relevance of DL-MAP and UL-MAP (TDD)

Figure 60—Maximum time relevance of DL-MAP and UL-MAP (FDD)

Figure 61—Minimum time relevance of DL-MAP and UL-MAP (FDD)
6.3.7.5.1 WirelessMAN-SC PHY

Allocation Start Time shall be subject to the following limitations: For FDD, the minimum Allocation Start Time value shall be the round trip delay + \( T_{\text{proc}} \), and the maximum Allocation Start Time value is \( T_f \) (i.e., the beginning of the next frame). For TDD, the Allocation Start Time value shall be either the ATDD split or the ATDD split + \( T_f \). The allocation shall be within a single frame.

6.3.7.5.2 WirelessMAN-OFDM PHY

Allocation Start Time shall be subject to the following limitations:

- For FDD, the minimum Allocation Start Time value shall be the round trip delay + \( T_{\text{proc}} \), and the maximum Allocation Start Time value is \( T_f \) (i.e., the beginning of the next frame).
- For TDD, the Allocation Start Time value shall be either the ATDD split or the ATDD split + \( T_f \), and the allocation shall be within a single frame. The allocation start time shall be no smaller than the round trip delay + \( T_{\text{proc}} \).

6.3.7.5.3 WirelessMAN-OFDMA PHY

Allocation Start Time shall be subject to the following limitations:

- Minimum value: Allocation Start Time \( \geq T_f \)
- Maximum value: Allocation Start Time \( < 2 \times T_f \)

In the UL subframe for which the MS fails to receive the relevant UL MAP, the MS shall not send data bursts or control signals (including CDMA ranging, CQICH, HARQ ACK/NAK, or sounding signals).

6.3.7.6 Optional MAC AAS support of OFDM and OFDMA

6.3.7.6.1 AAS MAC services

AAS (see Cantoni and Godara [B4], Johnson and Dudgeon [B37], Liberti and Rappaport [B38], and Branlund [B3] for generic literature), through the use of more than one antenna element, can improve range and system capacity by adapting the antenna pattern and concentrating its radiation to each individual subscriber. The spectral efficiency can be increased linearly with the number of antenna elements. This is achieved by steering beams to multiple users simultaneously to realize an inter-cell frequency reuse of one and an in-cell reuse factor proportional to the number of antenna elements. An additional benefit is the signal-to-noise ratio (SNR) gain realized by coherently combining multiple signals, and the ability to direct this gain to particular users. Another possible benefit is the reduction in interference achieved by steering nulls in the direction of co-channel interferers. Combining the benefits of increasing the SNR of certain subscribers and steering nulls to others, enables bursts to be concurrently transmitted to spatially separated SSs. For the UL direction the same principle can be applied in a reciprocal fashion. A concurrent transmission of bursts does not necessarily increase the system’s range but may enhance system capacity.

Support mechanisms for AAS are specified, which allow a system to deliver the benefits of adaptive arrays while maintaining compatibility for non-AAS SSs.

The design of the AAS option provides a mechanism to migrate from a non-AAS system to an AAS-enabled system in which the initial replacement of the non-AAS capable BS by an AAS capable BS should cause the only service interruption to (non-AAS) SSs.
This is achieved by dedicating part of the frame to non-AAS traffic and part to AAS traffic. The allocation is performed dynamically by the BS. Non-AAS SSs shall ignore AAS traffic, which they can identify based on the DL-MAP/UL-MAP messages.

For SC and OFDM systems, the AAS part of the DL frame begins with an AAS-specific preamble (see Figure 62 and Figure 63). Note that this DL preamble does not apply to the OFDMA PHY.

![Figure 62—AAS zone, FDD](image)

For BR/allocation, AAS-enabled SSs may use dedicated private DL-MAP/UL-MAP messages as well as tools specific for AAS (see specific PHY subclauses), which can be used to facilitate avoidance of collisions with non-AAS traffic.

Special considerations apply to those parts of the frame that are not scheduled, e.g., initial ranging and BR, as discussed in 6.3.7.6.3 and 6.3.7.6.6.

### 6.3.7.6.2 MAC control functions

The control of the AAS part of the frame may be done by unicasting private management messages to individual SSs. These messages shall be the same as the broadcast management messages, except that the Basic CID assigned to the SS is used instead of the Broadcast CID.

If AAS-enabled SSs can decode the broadcast DL-MAP and DCD messages, the BS may specify concurrent bursts by means of the extended concurrent transmission IE format as described in 8.3.6.2.6.
6.3.7.6.3 AAS DL synchronization

When the SS first attempts to synchronize to the DL transmission, the BS is unaware of its presence, and therefore is not aiming the adaptive array at its direction. Nevertheless, the frame start preamble is a repetitive well-known pattern, and SS may utilize the inherent processing gain associated with it in order to synchronize timing and frequency parameters with the BS. The BS may further employ active scanning or diversity methods to speed up and enhance the process of DL synchronization. These methods are PHY-specific, and described in the respective PHY section.

6.3.7.6.4 Alerting the BS about presence of a new SS in an AAS system

In a non-AAS system, after synchronizing to the DL, an SS attempts to obtain the DL parameters by decoding the DL-MAP and DCD messages. In an AAS system, an SS may be able to obtain the DL parameters if it receives the broadcast channel with enough energy so it can decode the DL-MAP and DCD messages. If this is the case, the SS can continue with the network entry process just like the non-AAS case, and the BS will get the chance to tune the adaptive array to it during the ranging process.

Alternatively, for SC and OFDM systems, an AAS SS may use the following procedure to alert the BS to its presence, so the BS can adapt its antenna array to the SS position.

An AAS BS may reserve a fixed, predefined part of the frame as initial ranging contention slots for this alert procedure. The number of contention slots and their location in the frame is PHY-specific (see 8.3.7.2, 8.4.4.1, respectively). These contention slots shall be called AAS-alert-slots.

When an AAS SS has synchronized to the DL, yet is unable to obtain the DL parameters because it cannot decode the DL-MAP and DCD messages, it shall attempt initial ranging on the AAS-alert-slots. Unlike usual initial ranging, the SS shall use all available contention slots, in order to allow the BS adaptive array enough time and processing gain to shape the beam for it. After such an attempt the SS shall wait for a transmission containing DL-MAP and DCD messages from the BS, and shall continue the network entry process like a non-AAS SS.

If the DL-MAP and DCD messages fail to arrive, the SS shall use an exponential backoff algorithm for selecting the next frame in which to attempt alerting the BS to its presence. The algorithm shall be the same as that used for initial ranging by non-AAS stations (see 6.3.8).

6.3.7.6.5 FDD/TDD support

Adaptive Arrays use channel state information in the PHY at both DL and UL. When channel state of the DL is required at the BS, there are two ways to obtain it:

- By relying on reciprocity, thus using the UL channel state estimation as the DL channel state.
- By using feedback, thus transmitting the estimated channel state from the SS to BS.

The first method is simpler and is well suited for TDD systems. The second method is more suitable for FDD systems, where reciprocity does not apply (due to the large frequency separation between UL and DL channels). The second method may also be used for TDD systems.

Channel state information is obtained by using two MAC control messages: AAS-FBCK-REQ and AAS-FBCK-RSP (see 6.3.2.3.35). The request instructs the SS to measure, the results of which shall be returned in the response after the measurement period has ended. The BS shall provide an UL allocation to enable the SS to transmit this response. Using FDD, the BS shall issue AAS-FBCK-REQ messages. Using TDD, the BS may issue AAS-FBCK messages.
6.3.7.6.6 Requesting bandwidth

AAS subscribers might not be able to request bandwidth using the usual contention mechanism. This happens because the adaptive array may not have a beam directed at the SS when it is requesting bandwidth, and the BR will be lost. In order to avoid this situation, an AAS SS is directed by the BS about whether it may use broadcast allocations for requesting bandwidth. The BS may change its direction dynamically using the AAS broadcast permission TLV, which is carried by the RNG-RSP message. The SS shall signify by using the AAS broadcast capability TLV in the RNG-REQ message whether it can receive the broadcast messages.

When an SS is directed not to use the Broadcast CID to request bandwidth, it is the responsibility of the BS to provide a polling mechanism to learn about the SS bandwidth requirements.

6.3.8 Contention resolution

The BS controls assignments on the UL channel through the UL-MAP messages and determines which minislots are subject to collisions. Collisions may occur during initial ranging and request intervals defined by their respective IEs. The potential occurrence of collisions in request intervals is dependent on the CID in the respective IE. This subclause describes UL transmission and contention resolution. For simplicity, it refers to the decisions an SS makes. Since an SS can have multiple UL service flows (each with its own CID), it makes these decisions on a per CID or per service QoS basis.

The mandatory method of contention resolution that shall be supported is based on a truncated binary exponential backoff, with the initial backoff window and the maximum backoff window controlled by the BS. The values are specified as part of the UCD message and represent a power-of-two value. For example, a value of 4 indicates a window between 0 and 15; a value of 10 indicates a window between 0 and 1023.

When an SS has information to send and wants to enter the contention resolution process, it sets its internal backoff window equal to the request (or ranging for initial ranging) backoff start defined in the UCD message referenced by the UCD Count in the UL-MAP message currently in effect.15

The SS shall randomly select a number within its backoff window. This random value indicates the number of contention transmission opportunities that the SS shall defer before transmitting. An SS shall consider only contention transmission opportunities for which this transmission would have been eligible. These are defined by Request IEs (or Initial Ranging IEs for initial ranging) in the UL-MAP messages. Note that each IE may consist of multiple contention transmission opportunities.

Using BRs as an example, consider an SS whose initial backoff window is 0 to 15 and assume it randomly selects the number 11. The SS shall defer a total of 11 contention transmission opportunities. If the first available Request IE is for 6 requests, the SS does not use this and has 5 more opportunities to defer. If the next Request IE is for 2 requests, the SS has 3 more to defer. If the third Request IE is for 8 requests, the SS transmits on the fourth opportunity, after deferring for 3 more opportunities.

After a contention transmission, the SS waits for a Data Grant Burst Type IE in a subsequent map (or waits for a RNG-RSP message for initial ranging). Once received, the contention resolution is complete.

The SS shall consider the contention transmission lost if no data grant has been received in the number of subsequent UL-MAP messages specified by the Contention-Based Reservation Timeout parameter (or no response within T3 for initial ranging). The SS shall now increase its backoff window by a factor of two, as long as it is less than the maximum backoff window. The SS shall randomly select a number within its new backoff window and repeat the deferring process described above.

---

15The map currently in effect is the map whose allocation start time has occurred but which includes IEs that have not occurred.
This retry process continues until the maximum number (i.e., request retries for BRs and contention ranging retries for initial ranging) of retries has been reached. At this time, for BRs, the PDU shall be discarded. For initial ranging, proper actions are specified in 6.3.9.5. Note that the maximum number of retries is independent of the initial and maximum backoff windows that are defined by the BS.

For BRs, if the SS receives a unicast Request IE or Data Grant Burst Type IE at any time while deferring for this CID, it shall stop the contention resolution process and use the explicit transmission opportunity.

The BS has much flexibility in controlling the contention resolution. At one extreme, the BS may choose to set up the request (or ranging) backoff start and request (or ranging) backoff end to emulate an Ethernet-style backoff with its associated simplicity and distributed nature as well as its fairness and efficiency issues. This would be done by setting request (or ranging) backoff start = 0 and request (or ranging) backoff end = 10 in the UCD message. At the other end, the BS may make the request (or ranging) backoff start and request (or ranging) backoff end identical and frequently update these values in the UCD message so that all SS are using the same, and hopefully optimal, backoff window.

6.3.8.1 Transmission opportunities

A transmission opportunity is defined as an allocation provided in a UL-MAP or part thereof intended for a group of SSs authorized to transmit BRs or initial ranging requests. This group may include either all SSs having an intention to join the cell or all registered SSs or a multicast polling group. The number of transmission opportunities associated with a particular IE in a map is dependent on the total size of the allocation as well as the size of an individual transmission.

The size of an individual transmission opportunity for each type of contention IE shall be published in each transmitted UCD message. The BS shall always allocate bandwidth for contention IEs in integer multiples of these published values.

As an example, consider contention-based BRs for a WirelessMAN-SC system where the PHY protocol has a frame duration of 1 ms, 4 symbols for each PS, 2 PSs for each minislot, an UL preamble of 16 symbols (i.e., 2 minislots), and an SS transition gap (SSTG) of 24 symbols (i.e., 3 minislots). Thus, assuming quadrature phase-shift keying (QPSK) modulation, each transmission opportunity requires 8 minislots: 3 for the SSTG, 2 for the preamble, and 3 for the BR message. This payload requirement would be specified as a value of 16 assigned to the UCD TLV “Bandwidth request opportunity size.”

If the BS schedules a Request IE of, for example, 24 minislots, there will be three transmission opportunities within this IE. Details of the three transmission opportunities are shown in Figure 64.

![Figure 64—Example of Request IE containing multiple transmission opportunities](image-url)
6.3.9 Network entry and initialization

Systems shall support the applicable procedures for entering and registering a new SS or a new node to the network. All network entry procedures described hereunder through and including 6.3.9.13 apply only to PMP operation.

The procedure for initialization of an SS shall be as shown in Figure 65. This figure shows the overall flow between the stages of initialization in an SS. This shows no error paths and is shown simply to provide an overview of the process. The more detailed finite state machine representations of the individual sections (including error paths) are shown in the subsequent figures. Timeout values are defined in 10.1.

The procedure can be divided into the following phases:

a) Scan for DL channel and establish synchronization with the BS
b) Obtain Tx parameters (from UCD message)
c) Perform ranging

Figure 65—SS initialization overview
d) Negotiate basic capabilities  
e) Authorize SS and perform key exchange  
f) Perform registration  
g) Establish IP connectivity  
h) Establish time of day  
i) Transfer operational parameters  
j) Set up connections

Implementation of phase e) is optional. This phase shall be performed if both SS and BS support Authorization Policy. Implementation of phases g), h), and i) at the SS is optional. These phases shall only be performed if the SS has indicated in the REG-REQ message that it is a managed SS.

Each SS contains the following information when shipped from the manufacturer:

— A 48-bit universal MAC address (per IEEE Std 802) assigned during the manufacturing process. This is used to identify the SS to the various provisioning servers during initialization.
— Security information as defined in Clause 7 (e.g., X.509 certificate) used to authenticate the SS to the security server and authenticate the responses from the security and provisioning servers.

6.3.9.1 Scanning and synchronization to the DL

On initialization or after signal loss, the SS shall acquire a DL channel. The SS shall have nonvolatile storage in which the last operational parameters are stored and may first try to reacquire this DL channel. If this fails, it shall begin to scan the possible channels of the DL frequency band of operation until it finds a valid DL signal.

Once the PHY has achieved synchronization, as given by a PHY Indication, the MAC shall attempt to acquire the channel control parameters for the DL and then the UL.

6.3.9.2 Obtain DL parameters

The MAC shall search for the DL-MAP MAC management messages. The SS achieves MAC synchronization once it has received at least one DL-MAP message and has acquired the DL-Burst Profiles information. An SS MAC remains in synchronization as long as it continues to successfully receive the DL-MAP and DCD messages for its Channel. An MS may use information received in the DCD or MOB_NBR-ADV messages, such as the Available DL Radio Resources and Cell Type (11.4.1), to determine whether the channel is suitable for its intended use and whether it should continue scanning for other channels. If the Lost DL-MAP Interval (Table 554) has elapsed without a valid DL-MAP message or the T1 interval (Table 554) has elapsed without a valid DCD message, an SS shall try to reestablish synchronization. The process of acquiring synchronization is illustrated in Figure 66. The process of maintaining synchronization is illustrated in Figure 67.
Figure 66—Obtaining DL synchronization
6.3.9.3 Obtain UL parameters

After synchronization, the SS shall wait for a UCD message from the BS in order to retrieve a set of transmission parameters for a possible UL channel. These messages are transmitted periodically from the BS for all available UL channels and are addressed to the MAC broadcast address.

If no UL channel can be found after a suitable timeout period, then the SS shall continue scanning to find another DL channel. An MS may use information received in the UCD or MOB_NBR-ADV messages, such as the Available UL Radio Resources, to determine whether the channel is suitable for its intended use and whether it should continue scanning for other channels. The process of obtaining UL parameters is illustrated in Figure 68.

The SS shall determine from the channel description parameters whether it may use the UL channel. For FDD, the BS shall include the Frequency parameter in the UCD with a UL center frequency value different than the DL center frequency value of the Frequency parameter in the DCD. The SS shall interpret the different UL center frequency value as explicit indication that the duplexing technique for the channel is FDD. For TDD, the BS may include the Frequency parameter in the UCD with a UL center frequency value the same as the DL center frequency value of the Frequency parameter in the DCD. The SS shall interpret a UL center frequency value equal to the DL center frequency value, or the absence of any Frequency TLV in the UCD as explicit indication that the duplexing technique for the channel is TDD. If the channel is not suitable, then the SS shall continue scanning to find another DL channel until all channels are exhausted. If the channel is suitable, the SS shall extract the parameters for this UL from the UCD. Then, the SS shall wait for a bandwidth allocation map for the selected channel. It may begin transmitting UL in accordance with the MAC operation and the bandwidth allocation mechanism.

If, after scanning all channels, the SS does not find a suitable channel, the SS may choose the most appropriate channel based on conditions that include RSSI, CINR, cell type and the available radio resources of all channels to perform initial ranging according to 6.3.9.5.

The SS shall perform initial ranging at least once, per Figure 70 and Figure 71 (in 6.3.9.6). If initial ranging is not successful, the procedure is restarted from scanning to find another DL channel.
The SS MAC is considered to have valid UL parameters as long as it continues to successfully receive the UL-MAP and UCD messages. If at least one of these messages is not received within the time intervals specified in Table 554, the SS shall not use the UL. This is illustrated in Figure 69.

![Figure 68—Obtaining UL parameters](image-url)
6.3.9.4 Message flows during scanning and UL parameter acquisition

The BS shall generate UCD and DCD messages on the DL at periodic intervals within the ranges defined in Table 554. The BS may generate UL-MAP and DL-MAP at intervals as specified in a particular PHY specification. These messages are addressed to all SSs. Refer to Table 177.

6.3.9.5 Initial ranging and automatic adjustments

Ranging is the process of acquiring the correct timing offset and power adjustments so that the SS’s transmissions are aligned to a symbol that marks the beginning of a minislot boundary in SC and Sca PHY, or aligned with the BS receive frame for OFDM and OFDMA PHY, and received within the appropriate reception thresholds. The timing delays through the PHY shall be relatively constant. Any variation in the PHY delays shall be accounted for in the guard time of the UL PHY overhead.

6.3.9.5.1 Contention-based initial ranging and automatic adjustments

First, an SS shall synchronize to the DL and learn the UL channel characteristics through the UCD MAC management message. At this point, the SS shall scan the UL-MAP message to find an initial ranging interval. The BS shall allocate an initial ranging interval consisting of one or more transmission opportunities. For SC and OFDM PHY, the size of each transmission opportunity shall be as specified by the UCD TLV, Ranging Request Opportunity Size.

For SC and OFDM PHY, the SS shall put together a RNG-REQ message to be sent in an initial ranging interval. The duration of the burst carrying the RNG-REQ message shall be as specified in the Ranging Request Burst Size TLV (see 11.3.1). The CID field shall be set to the noninitialized SS value (zero). For the OFDM PHY, the initial ranging process may include a subchannelized mechanism specified in 8.3.7.2. For the OFDMA PHY, the initial ranging process shall begin by sending initial ranging CDMA codes on the UL allocation dedicated for that purpose (for more details see 6.3.10.3), instead of RNG-REQ messages sent on contention slots.

For OFDMA PHY, when the BS is FDD and the SS is H-FDD, then the SS shall always use Group 1 for all purposes for initial network entry and re-entry.

Ranging adjusts each SS’s timing offset such that it appears to be co-located with the BS. The SS shall set its initial timing offset to the amount of internal fixed delay and this amount includes delays introduced through a particular implementation and shall include the downlink PHY interleaving latency, if any. In TDD with OFDMA PHY systems, if the BS transmits the UL_initial_transmit timing TLV in the UCD, the SSs transmit timing shall be referenced to the value indicated by this TLV. Otherwise, the SS transmit timing shall be referenced to the “UL Allocation Start Time” value specified in the UL-MAP.

If the Ranging Abort Timer TLV encoding is included in RNG-RSP, the MS shall abort the current network entry attempt and shall not redo ranging to the current BS until the Ranging Abort Timer expires.

When the initial ranging transmission opportunity occurs, the SS shall send the RNG-REQ message (or a CDMA code in case of the OFDMA PHY). Thus, the SS sends the message as if it were colocated with the BS.

The SS shall calculate the maximum Tx signal strength for initial ranging, \( P_{TX\_IR\_MAX} \), from Equation (2).

\[
P_{TX\_IR\_MAX} = \text{EIRx} P_{IR,max} + \text{BS\_EIRP} - \text{RSS}
\]  

where the \( \text{EIRx} P_{IR,max} \) and \( \text{BS\_EIRP} \) are obtained from the DCD, and \( \text{RSS} \) is the measured RSSI, by the SS, as described in the respective PHY.

In the case that the Rx and Tx gain of the SS antennae are substantially different, the SS shall use Equation (3).

\[
P_{TX\_IR\_MAX} = \text{EIRx} P_{IR,max} + \text{BS\_EIRP} - \text{RSS} + \left( G_{RX\_SS} - G_{TX\_SS} \right)
\]

where

\( G_{RX\_SS} \) is the SS Rx antenna gain

\( G_{TX\_SS} \) is the SS Tx antenna gain

In the case that the EIR \( \times P_{IR,max} \) and/or \( \text{BS\_EIRP} \) is not known, the SS shall start from its minimum Tx power level.
NOTE 1—The $EIRx P_{IR,\text{max}}$ is the maximum equivalent isotropic received power, which is computed for a simple single-antenna receiver as $\text{RSSIR,\text{max}} – \text{GANT BS Rx}$, where the $\text{RSSIR,\text{max}}$ is the received signal strength at antenna output and $\text{GANT BS Rx}$ is the receive antenna gain. The $\text{BS_E IRP}$ is the equivalent isotropic radiated power of the BS, which is computed for a simple single-antenna transmitter as $P_{\text{Tx}} + \text{GANT BS Tx}$, where $P_{\text{Tx}}$ is the Tx power and $\text{GANT BS Tx}$ is the Tx antenna gain.

For SC and OFDM PHY, the SS shall send the RNG-REQ at a power level below $P_{\text{TX IR MAX}}$, measured at the antenna connector. If the SS does not receive a response, the SS shall resend the RNG-REQ at the next appropriate initial ranging transmission opportunity and adjust its power level. If the SS receives a response containing the frame number in which the RNG-REQ was transmitted, it shall consider the transmission attempt unsuccessful but implement the corrections specified in the RNG-RSP and issue another RNG-REQ message after the appropriate backoff delay. If the SS receives a response containing its MAC Address, it shall consider the RNG-RSP reception successful. If the SS does not receive a response, the SS shall resend the RNG-REQ at the next appropriate initial ranging transmission opportunity and adjust its power level.

When a WirelessMAN-OFDM BS detects a transmission in the ranging slot that it is unable to decode, it may respond by transmitting a RNG-RSP that includes transmission parameters, but identifies the frame number and frame opportunity when the transmission was received instead of the MAC Address of the transmitting SS.

For OFDMA, the SS shall send a CDMA code at a power level below $P_{\text{TX IR MAX}}$, measured at the antenna connector. If the SS does not receive a response, the SS shall send a new CDMA code at the next appropriate initial ranging transmission opportunity and adjust its power level. If the SS receives a RNG-RSP message containing the parameters of the code it has transmitted and status Continue, it shall consider the transmission attempt unsuccessful but implement the corrections specified in the RNG-RSP and issue another CDMA code after random selection of one Ranging Slot in a single frame. If the SS receives an UL-MAP containing a CDMA Allocation IE with the parameters of the code it has transmitted, it shall consider the RNG-RSP reception successful, and proceed to send a unicast RNG-REQ on the allocated bandwidth. More details on this procedure can be found in 6.3.10.3.

Once the BS has successfully received the RNG-REQ message, it shall return a RNG-RSP message using the Initial Ranging CID. Within the RNG-RSP message shall be the Basic and Primary Management CIDs assigned to this SS. The message shall also contain information on RF power level adjustment and offset frequency adjustment as well as any timing offset corrections. At this point the BS shall start using invited initial ranging intervals addressed to the SS’s Basic CID to complete the ranging process, unless the status of the RNG-RSP message is success, in which case the initial ranging procedure shall end.

If the status of the RNG-RSP message is continue, the SS shall wait for an individual initial ranging interval assigned to its Basic CID. Using this interval, the SS shall transmit another RNG-REQ message using the Basic CID along with any power level and timing offset corrections. In OFDM PHY, in this case, the RNG-REQ message will be transmitted with padding of unused part of the Initial Ranging Opportunity Interval.

The BS shall return another RNG-RSP message to the SS with any additional fine tuning required. The ranging request/response steps shall be repeated until the response contains a ranging successful notification or the BS aborts ranging. Once successfully ranged (RNG-REQ is within tolerance of the BS), the SS shall join normal data traffic in the UL. In particular, state machines and the applicability of retry counts and timer values for the ranging process are defined in Table 554.

NOTE 2—The burst profile to use for any UL transmission is defined by the uplink interval usage code (UIUC). Each UIUC is mapped to a burst profile in the UCD message.

For SC and OFDM PHY, the message sequence chart (Table 178) and flow charts (Figure 70, Figure 71, Figure 72, and Figure 73) in 6.3.9.6 define the ranging and adjustment process that shall be followed by compliant SSs and BSs. For OFDMA PHY, these details can be found in 6.3.10.3.

a WirelessMAN-OFDM PHY only.
NOTE 1—The BS shall allow the SS sufficient time to have processed the previous RNG-RSP (i.e., to modify the transmitter parameters) before sending the SS a specific ranging opportunity. This is defined as SS ranging response processing time in Table 554.

NOTE 2—For multichannel support, the SS shall attempt initial ranging on every suitable UL channel before moving to the next available DL channel. Suitability of a channel is determined by conditions that include RSSI, CINR, Cell Type, Available DL Radio Resources and Available UL Radio Resources.

During initial Network Entry, a BS may decide to re-direct the ranging SS to another channel by sending the RNG-RSP with an Offset Frequency Adjustment pointing to the other channel. If the Offset Frequency Adjustment value is less than half of the channel bandwidth, this is fine-frequency adjustment within the ranged channel, otherwise, the value is a reassignment to a different channel.

On receiving a RNG-RSP instruction to move to a new DL frequency, the SS shall consider any previously assigned Basic, Primary Management, and Secondary Management CIDs to be deassigned and shall obtain new Basic, Primary Management, and Secondary Management CIDs via initial ranging and registration.

It is possible that the RNG-RSP may be lost after transmission by the BS. The SS shall recover by timing out and reissuing its Initial RNG-REQ. Since the SS is uniquely identified by the source MAC address in the ranging request, the BS may immediately reuse the Basic, Primary Management, and Secondary Management CIDs previously assigned. If the BS assigns new Basic, Primary Management, and Secondary Management CIDs, it shall make some provision for aging out the old CIDs that went unused.

For MSs that are employing the optional association procedure, and to which the MS and BS are currently associated, the MS may use its unexpired, previously obtained and retained associated ranging Tx parameters to set initial ranging values including PTX_IR_MAX power levels.

### 6.3.9.6 Ranging parameter adjustment

Adjustment of local parameters (e.g., Tx power) in an SS as a result of the receipt (or non receipt) of a RNG-RSP is considered to be implementation-dependent with the following restrictions:

1. **All parameters shall be within the approved range at all times.**
2. **Power adjustment shall start from the initial value selected with the algorithm described in 6.3.9.5 unless a valid power setting is available from nonvolatile storage, in which case this value may be used as the starting point.**
3. **Power adjustment shall be capable of being reduced or increased by the specified amount in response to RNG-RSP messages.**
4. **If, during initialization, power is increased to the maximum value P_{TX_IR_MAX} (with a response from the BS) or to its maximum capability (without a response from the BS), it shall wrap back to the minimum.**
5. **If power is increased to the maximum value P_{TX_IR_MAX} during initialization in a TDD system without a response from the BS, the SS shall wrap power back to the minimum. If the power is increased to its maximum capability during initialization in an FDD system without a response from the BS, the SS shall wrap power back to the minimum.**

On receiving a RNG-RSP, the SS shall not transmit until the RF signal has been adjusted in accordance with the RNG-RSP and has stabilized. See Figure 70 through Figure 74.
Wait for initial ranging opportunity

Timeout T2

Scan for DL channel

UL-MAP with ranging opportunity

Send RNG-REQ

Start T3

Wait for RNG-RSP

Figure 70—Initial ranging—SS (part 1)
NOTE—Timeout T3 may occur because the RNG-REQs from multiple SSs collided. T3 timeouts can also occur during multichannel operation. On a system with multiple UL channels, the SS shall attempt initial ranging on every suitable UL channel before moving to the next available DL channel.

Figure 71—Initial ranging—SS (part 2)
Figure 72—Initial ranging—BS
Figure 73—Initial ranging, polled phase—BS
For systems operating below 11 GHz, the BS may in addition respond to undecodable messages in an initial ranging slot as shown in Figure 74.

![Figure 74—Initial ranging—BS response to undecodable message](image)

### 6.3.9.7 Negotiate basic capabilities

Immediately after completion of ranging, the SS informs the BS of its basic capabilities by transmitting an SBC-REQ message with its capabilities set to “on” (see Figure 75). The BS responds with an SBC-RSP message with the intersection of the SS’s and the BS’s capabilities set to “on” (see Figure 76 and Figure 77, respectively).

![Figure 75—Negotiating basic capabilities—SS](image)
Figure 76— Handle SBC-RSP, SS side
Figure 77—Handling SBC-REQ first reception, BS side
6.3.9.8 SS authorization and key exchange

If PKM is enabled (see 11.8.4), the BS and SS shall perform authorization and key exchange as described in 7.2.

If MIH query capability during network entry is enabled (refer to 11.4.1 and 11.8.10), the BS and MS may perform MIH query using PKM messages before authorization and key exchange.

6.3.9.9 Registration

Registration is the process by which the SS is allowed entry into the network and a managed SS receives its Secondary Management CID and thus becomes manageable. To register with a BS, the SS shall send a REG-REQ message to the BS. The BS shall respond with a REG-RSP message. For an SS that has indicated being a managed SS in the REG-REQ message, the REG-RSP message shall include the Secondary Management CID. Figure 79 shows the procedure that shall be followed by the SS.
Once the SS has sent a REG-REQ to the BS, it shall wait for a REG-RSP to authorize it to forward traffic to the network. Figure 80 shows the waiting procedure that shall be followed by the SS.

Figure 79—Registration—SS

Figure 80—Handling REG-RSP
The BS shall perform the operations shown in Figure 81.

![Diagram](image-url)

**Figure 81—Handle REG-REQ first reception—BS**
Figure 82 describes the NW entry process on the BS side. The transitions and states that are marked with asterisks (*) apply only to OFDMA PHY.

Figure 82—Network entry state machine, BS side
Figure 83 describes the NW entry process on the MS side. The transitions and states that are marked with asterisks (*) apply only to OFDMA PHY.

Figure 83—Network entry state machine, SS side
Figure 84 describes the Ranging procedure within the NW entry process on the MS side. The transitions and states that are marked with asterisks (*) apply only to OFDMA.

For managed SS, upon sending a REG-RSP, the BS shall wait for a TFTP-CPLT. If timer T13 (defined in Table 554) expires, the BS shall both deassign the management CIDs from that SS and make some provision for aging out those CIDs (see Figure 85 and Figure 86).

6.3.9.9.1 IP version negotiation

The SS may include the IP Version (11.7.4) parameter in the REG-REQ to indicate which versions of IP it supports on the secondary management connection. When present in the REG-REQ, the BS shall include the IP Version parameter (11.7.4) in the REG-RSP to command the SS to use the indicated version of IP on the secondary management connection. The BS shall command the use of exactly one of the IP versions supported by the SS.

The omission of the IP Version parameter in the REG-REQ shall be interpreted as IPv4 support only. Consequently, omission of the IP Version parameter in the REG-RSP shall be interpreted as a command to use IPv4 on the secondary management connection.
6.3.9.10 Establishing IP connectivity

For an MS, if mobile IP is being used, the MS may secure its address on the secondary management connection using mobile IP.

Otherwise, for all SSs and for MSs using IPv4 and not using mobile IP, they shall invoke DHCP mechanisms (IETF RFC 2131) in order to obtain an IP address and any other parameters needed to establish IP connectivity. If the SS has a configuration file, the DHCP response shall contain the name of a file that contains further configuration parameters. For SSs using IPv6, they shall either invoke DHCPv6 (IETF RFC 3315) or IPv6 Stateless Address Autoconfiguration (IETF RFC 2462) based on the value of a TLV tuple in REG-RSP. For a managed SS, IP connectivity shall be performed on the SS’s secondary management connection.

The IP version parameter shall be included in the TLV for a managed SS (see 11.7.4 for the TLV).

Table 179—Establishing IP connectivity

</tr>
</tbody>
</table>

6.3.9.11 Establishing time of day

The SS and BS need to have the current date and time. This is required for time-stamping logged events for retrieval by the management system. This need not be authenticated and need be accurate only to the nearest second.

The protocol by which the time of day shall be retrieved is defined in IETF RFC 868. Refer to Table 180. The request and response shall be transferred using UDP. The time retrieved from the server [universal coordinated time (UTC)] shall be combined with the time offset received from the DHCP response to create
the current local time. Establishment of time of day shall be performed on the SS’s secondary management connection.

### Table 180—Establishing time of day

<table>
<thead>
<tr>
<th>SS</th>
<th>Time Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>send request to time server</td>
<td>--------------</td>
</tr>
<tr>

<td>process request</td>
<td></td>
</tr>
<tr>
<td>&lt;------------time of day response--------</td>
<td></td>
</tr>
<tr>
<td>set up / correct time of day from response</td>
<td></td>
</tr>
</tbody>
</table>

Successfully acquiring the Time of Day is not mandatory for a successful registration, but is necessary for ongoing operation. The specific timeout for Time of Day Requests is implementation dependent. However, the SS shall not exceed more than three Time of Day requests in any five-minute period.

### 6.3.9.12 Transferring operational parameters

After DHCP is successful, the SS shall download the SS Configuration File (9.2) using TFTP on the SS’s secondary management connection, as shown in Table 181 if specified in the DHCP response. The TFTP Configuration File server is specified by the “siaddr” field of the DHCP response. The SS shall use an adaptive timeout for TFTP based on binary exponential backoff (IETF RFC 1123, IETF RFC 2349).

### Table 181—Transferring operational parameters

<td>----------------------------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
The parameter fields required in the DHCP response and the format and content of the configuration file shall be as defined in 9.2. Note that these fields are the minimum required for interoperability.

When the configuration file download has completed successfully, the SS shall notify the BS by transmitting a TFTP-CPLT message on the SS’s primary management connection. Transmissions shall continue periodically until a TFTP-RSP message is received with “OK” response from the BS (see Figure 85 and Figure 86) or the SS terminates retransmission due to retry exhaustion.

Figure 85—Waiting for TFTP-CPLT—BS

Figure 86—Waiting for TFTP-RSP—SS
6.3.9.13 Establishing provisioned connections

After the transfer of operational parameters (for managed SS) or after registration (for unmanaged SS), the BS shall send DSA-REQ messages to the SS to set up connections for preprovisioned service flows belonging to the SS. The SS responds with DSA-RSP messages. This is described further in 6.3.14.7.1.

6.3.9.14 Forcing MSs to perform network entry at once

A BS may restart due to a critical error or an operator’s intention. The BS has the restart count as the number of times in which the BS restarts. This restart count is incremented by one whenever BS restarts. The restart count as TLV encoding is included in DCD message (refer to Table 575). The BS may intentionally increment the restart count to be included in DCD message for the purpose of forcing all MSs to perform the Network Entry due to some problem at the BS or an operator’s purpose.

After the BS restarts, it shall inform the MSs of its restart through the incremented restart count in DCD message. The restart count, which BS sent via DCD message, is saved in MS in order to recognize whether BS restarts or not.

Restart count is updated by every BS Restart Count TLV encoding in DCD message sent by BS. In other words, whenever MS receives DCD message, it shall compare the restart count in DCD message with the old one saved in it. If MS detects the restart count in DCD message different from old one save in MS, it shall perform Network Entry.

MOB_NBR-ADV message shall also include the BS Restart Count TLV for neighbor BS in each DCD_settings of DCD message. MS shall save the restart count of each neighbor BS for HO procedure. MS during HO shall compare the restart count of target BS through DCD message with the restart count of target BS saved in MS. As a result, if MS detects the restart of target BS, it shall perform the network entry.

6.3.10 Ranging

Ranging is a collection of processes by which the SS and BS maintain the quality of the RF communication link between them. Distinct processes are used for managing UL and DL. Also some PHY modes support ranging mechanisms unique to their capabilities.

6.3.10.1 DL burst profile management

This mechanism is not applicable to OFDMA PHY.

The DL operational burst profile is determined by the BS according to the quality of the signal that is received by each SS. To reduce the volume of UL traffic, the SS monitors the CINR and compares the average value against the allowed range of operation. This region is bounded by threshold levels. If the received CINR goes outside of the allowed operating region for the DL operational profile, the SS requests a change to a new operational burst profile using one of two methods. In the first method, the SS uses an allocated data grant to send a DBPC-REQ. In the second method, the SS uses the initial ranging interval to send a RNG-REQ. The second method can be used only in context with a request to change to a more robust profile. The SS determines the optimal method. If the first method is used and the SS has been granted UL bandwidth (a data grant allocation to the SS’s Basic CID), the SS shall send a DBPC-REQ message in that allocation. The BS responds with a DBPC-RSP message. If the second method is used and the SS requires a more robust burst profile on the DL, the SS shall send a RNG-REQ message in an initial ranging interval. With either method, the message is sent using the Basic CID of the SS. The coordination of message transmission and receipt relative to actual change of operational burst profile is different depending upon whether an SS is transitioning to a more or less robust burst profile. Figure 87 shows the case where an SS is transitioning to a more robust type. Figure 88 shows transition to a less robust burst profile.
The SS has full responsibility to determine its optimal burst profile.

Figure 87—Transition to more robust operational burst profile

- T30 Timeout

Notes:
- 1) Burst Profiles X, Y, Z ordered in decreasing robustness

Figure 89—State transition diagram for DL burst profile management—SS
6.3.10.2 UL periodic ranging

UL ranging consists of two procedures—initial ranging and periodic ranging. Initial ranging (see 6.3.9.5) allows an SS joining the network to acquire correct transmission parameters, such as time offset and Tx power level, so that the SS can communicate with the BS. Following initial ranging, periodic ranging allows the SS to adjust transmission parameters so that the SS can maintain UL communications with the BS.

The following summarizes the general algorithm for periodic ranging available to all PHY layers except OFDMA PHY. Diagrams of the SS and BS processes are provided in Figure 90, Figure 91, and Figure 92. CDMA-based ranging for OFDMA systems is described in 6.3.10.3.2.

a) For each SS, the BS shall maintain a T27 timer. At each expiration of the timer, the BS shall grant bandwidth to the SS for an UL transmission in the form of a data grant or an invited ranging opportunity. The timer is restarted each time a unicast grant is made to the SS. As a result, as long as the SS remains active, the BS does not specifically grant bandwidth to the SS for a ranging opportunity.

b) Each SS shall maintain a T4 timer. The expiration of this timer indicates to the SS that it has not been given the opportunity to transmit to the BS for an extended period of time. Operating on the assumption that its UL transmission parameters are no longer usable, the SS initiates a restart of its MAC operations.

c) For each unicast UL burst grant, the BS determines whether a transmitted signal is present. If no signal is detected in a specified number of successive grants, the BS shall terminate link management for the associated SS.

d) For each unicast uplink burst grant in which a signal is detected, the BS makes a determination as to the quality of the signal. If the signal is below BS acceptable reception threshold, the BS shall transmit a RNG-RSP (continue). This RNG-RSP (continue) may include corrections. If the signal is above the BS reception threshold, the BS may transmit a RNG-RSP (success). This RNG-RSP (success) may include corrections. If the BS receives a RNG-REQ, the BS shall transmit a RNG-RSP (success). This RNG-RSP (success) may include corrections. If a sufficient number of correction messages are issued without the SS signal quality becoming acceptable, the BS shall send the RNG-RSP message with a status of abort, and terminate link management of the SS.

e) The SS shall process each RNG-RSP message it receives, implementing any PHY corrections that are specified (when the status is continue) or initiating a restart of MAC activities (when the status is abort).

f) When the status of the last RNG-RSP message received is continue, the SS shall not use the data grant to service its UL connections except to transmit a RNG-REQ message.

g) When the SS cannot apply a correction, it shall send a RNG-REQ reporting the anomaly in the next data grant or invited ranging opportunity.

h) The SS shall respond to each uplink grant addressed to it and entirely fill the burst. If no data is pending and the last RNG-RSP was success, the SS shall fill the entire grant with a: RNG-REQ or “Padding PDU” or “stuff bytes.”
Figure 90—Periodic ranging receiver processing—BS
Figure 91—Periodic ranging opportunity allocation—BS
6.3.10.3 OFDMA-based ranging

The WirelessMAN-OFDMA PHY specifies a ranging subchannel and a set of special pseudonoise ranging codes. Subsets of codes shall be allocated in the UCD channel encoding for initial ranging, periodic ranging requests, and BRs so that the BS can determine the purpose of the received code by the subset to which the code belongs. An example of ranging channel in OFDMA frame structure is specified in Figure 228.
SSs that wish to perform one of the aforementioned operations shall select, with equal probability, one of the codes of the appropriate subset, modulate it onto the ranging subchannel, and subsequently transmit in ranging slot selected with equal probability from the available ranging slots on the UL subframe. An SS shall use either random selection or random backoff to select a Ranging Slot. When random selection is used, the SS shall select one Ranging Slot from all available slots in a single frame using a uniform random process. When random backoff is used, the SS shall select one Ranging Slot from all available Ranging Slots in the corresponding backoff window using a uniform random process. Details on the modulation and ranging codes are specified in 8.4.7.

For OFDMA PHY, the allocation of ranging opportunity inside a ranging allocation is defined in 8.4.7.4.

### 6.3.10.3.1 Contention-based initial ranging and automatic adjustments

A SS that wishes to perform initial ranging shall take the following steps:

- The SS, after acquiring downlink synchronization and uplink transmission parameters, shall select one Ranging Slot using the random backoff. The random backoff shall use a binary truncated exponent algorithm. After selecting the Ranging Slot, the SS shall choose a Ranging Code (from the Initial Ranging domain) using a uniform random process. The selected Ranging Code is sent to the BS (as a CDMA code) in the selected Ranging Slot.
- The BS cannot tell which SS sent the CDMA ranging request; therefore, upon successfully receiving a CDMA ranging code, the BS broadcasts a ranging response message that advertises the received ranging code as well as the ranging slot (OFDMA symbol number, subchannel, etc.) where the CDMA ranging code has been identified. This information is used by the SS that sent the CDMA ranging code to identify the ranging response message that corresponds to its ranging request. The ranging response message contains all the needed adjustment (e.g., time, power, and possibly frequency corrections) and a status notification.
- Upon receiving a ranging response message with Continue status, the SS shall continue the ranging process as done on the first entry (using random selection rather than random backoff) with ranging codes randomly chosen from the initial ranging domain sent on the periodic ranging region.
- When the BS receives an initial-ranging CDMA code that requires no corrections, the BS shall provide BW allocation for the SS using the CDMA_Allocation_IE to send a RNG-REQ message. Sending the RNG-RSP message with status “Success” is optional.
- Initial ranging process is over after receiving RNG-RSP message, which includes a valid Basic CID (following a RNG-REQ transmission on a CDMA Allocation IE). If this RNG-RSP message includes “continue” indication, the ranging process should be continued using the periodic ranging mechanisms.
- If the RNG-RSP includes an Offset Frequency Adjustment pointing to another channel and it is larger than the value required for a channel bandwidth offset, the SS should synchronize with the new channel indicated in the RNG-RSP.
- The timeout required for SS to wait for RNG-RSP, following or not following CDMA Allocation IE, is defined by T3.
- Using the OFDMA ranging mechanism, the periodic ranging timer is controlled by the SS, not the BS.

Adjustment of local parameters (e.g., Tx power) in an SS as a result of the receipt (or nonreceipt) of a RNG-RSP is considered to be implementation-dependent with the following restrictions:

a) All parameters shall be within the approved range at all times.
b) Power adjustment shall start from the initial value selected with the algorithm described in 6.3.9.5 unless a valid power setting is available from nonvolatile storage, in which case this value may be used as the starting point.
c) Power adjustment shall be capable of being reduced or increased by the specified amount in response to RNG-RSP messages.
d) If, during initialization, power is increased to the maximum value $P_{\text{TX IR MAX}}$ (without a response from the BS) or to its maximum capability (without a response from the BS), it shall wrap back to the minimum. On receiving a RNG-RSP, the SS shall not transmit until the RF signal has been adjusted in accordance with the RNG-RSP and has stabilized.

The message sequence chart (Table 182) and flow charts (Figure 93, Figure 94, Figure 95, Figure 97, and Figure 97) on the following pages define the CDMA initial ranging and adjustment process that shall be followed by compliant SSs and BSs.

6.3.10.3.2 Periodic ranging and automatic adjustments

An SS that wishes to perform periodic ranging shall take the following steps:

— The MS shall choose randomly a Ranging Slot (with random selection with equal probability from available Ranging Slots in a single frame) at the time to perform the ranging, then it chooses randomly a Periodic Ranging Code and sends it to the BS (as a CDMA code).
— If the MS does not receive a response, the MS may send a new CDMA code at the next appropriate periodic ranging transmission opportunity and adjust its power level up to $P_{TX_{IR\_MAX}}$ (6.3.9.5.1).
— The BS cannot tell which MS sent the CDMA ranging request; therefore, upon successfully receiving a CDMA periodic ranging code, the BS broadcasts a ranging response message that advertises the received periodic ranging code as well as the ranging slot (OFDMA symbol number, subchannel, etc.) where the CDMA periodic ranging code has been identified. This information is used by the SS that sent the CDMA periodic ranging code to identify the ranging response message that corresponds to its ranging request. The ranging response message contains all the needed adjustment (e.g., time, power, and possibly frequency corrections) and a status notification.
— Upon receiving a Ranging Response message with continue status, the MS shall continue the ranging process with further periodic ranging codes randomly chosen. Upon receiving a RNG-RSP message with success status, the MS shall restart timer T4.

Figure 99—Handle RNG-REQ retransmission after MS T3 timeout (OFDMA PHY only)
— Using the OFDMA ranging mechanism, the periodic ranging timer is controlled by the MS, not the BS.
— The BS may send an unsolicited RNG-RSP as a response to a CDMA-based bandwidth-request or any other data transmission from the MS.
— Upon timeout of MS internal T4 timer, the MS shall perform Periodic Ranging according to previous procedure.

When the SS receives an unsolicited RNG-RSP message, it shall reset the periodic ranging timer and adjust the parameters (timing and power, etc.) as notified in the RNG-RSP message.

The flow charts (Figure 100, Figure 101, and Figure 102) and message sequence chart (Table 183) on the following pages define the CDMA periodic ranging and adjustment process that shall be followed by compliant SSs and BSs.

6.3.10.4 CDMA HO ranging and automatic adjustment

An MS that wishes to perform HO ranging shall take a process similar to that defined in the initial ranging section with the following modifications.

In CDMA HO ranging process, the random selection is used instead of random backoff and the CDMA HO ranging code is used instead of the initial ranging code. The code is selected from the HO ranging domain as defined in 8.4.7.3.

Alternatively, if the BS is prenotified for the upcoming HO MS, it may provide bandwidth allocation information to the MS using Fast Ranging IE to send a RNG-REQ message.

6.3.10.4.1 Dedicated ranging and automatic adjustments

A dedicated ranging is an optional initial ranging that can be used to expedite the ranging process when the ranging is performed as an initial step of a certain procedure such as location determination, coordinated association during scanning, location update in idle mode, etc. For a dedicated ranging, BS will provide dedicated ranging information and allocate the dedicated ranging region at a pre-defined “rendezvous time,” in terms of relative frame number. The BS will also assign the following:

- A unique code number (from within the initial ranging codeset)
- A transmission opportunity within the allocated region (in terms of offset from the start of the region)

The BS may assign the same code or transmission opportunity to more than one MS, but not both. In case all allocated transmission opportunities in current region are different, there is no potential for collision of transmissions from different MSs. In case the BS allocates the same transmission opportunity to several MSs, there is some probability of collision and then BS may fail to identify transmitted codes.

The BS will provide the dedicated ranging information via MAC management messages, which are different according to the procedures for which the dedicated ranging is used.

When the “Dedicated ranging indicator” is set to 1, the ranging region will be allocated via UIUC=12 in the UL-MAP.

When the “Dedicated ranging indicator” is set to 1, then the ranging region and ranging method defined could be used for the purpose of ranging using dedicated CDMA code and transmit opportunity assigned in the unsolicited RNG-RSP message (for location determination of MS) or in the MOB_SCN-RSP message (for coordinated association).

MSs registered to this BS are prohibited from use of the named ranging region.

Upon receiving one of aforementioned messages which include the dedicated ranging information, the MS should interpret the provided rendezvous time, dedicated code, and transmission opportunity as follows:

- “Rendezvous time” specified the frame in which the BS will transmit a UL-MAP containing the definition of the dedicated ranging region where the MS can use the assigned CDMA ranging code. “Rendezvous time” is provided in units of frames, beginning at the frame where the MAC management message that includes the dedicated ranging information is transmitted.
- The MS shall read the UL-MAP transmitted at the first frame immediately following the rendezvous time and extract the description of the dedicated ranging region (ranging region with “Dedicated ranging indicator” bit set to 1). The MS shall determine the specific region it should use for transmission of the dedicated CDMA code by applying the offset defined by the “transmission opportunity offset” field in the management message, which was received from the BS, to the dedicated ranging region definition in the UL-MAP of the BS. In case the BS decides to provide a
regular (non-dedicated) ranging region with “Dedicated ranging indicator” set to 0, the MS may transmit the allocated CDMA code in the regular ranging region.

— If the MS could not obtain UL-MAP at the first frame immediately following the rendezvous time, it shall abort the dedicated ranging process. The MS may perform a contention-based ranging process as described in 6.3.10.3.1.

6.3.11 Update of channel descriptors

The channel descriptors (i.e., the UCD and DCD messages) are transmitted at regular intervals by the BS. Each descriptor contains the Configuration Change Count, which shall remain unchanged as long as the channel descriptor remains unchanged. All UL-MAP and DL-MAP messages allocating transmissions and receptions using burst profiles defined in a channel descriptor with a given Configuration Change Count value shall have a UCD/DCD Count value equal to the Configuration Change Count of the corresponding channel descriptor.

The procedure to transition from one generation of the channel descriptors (and, as a consequence, the set of burst profiles) to the next is shown in Table 184 and Table 185, for the UL and DL, respectively. The Configuration Change Count shall be incremented by 1 modulo 256 for every new generation of channel descriptor. After issuing a DL-MAP or UL-MAP message with the Configuration Change Count equal to that of the new generation, the old channel descriptor ceases to exist and the BS shall not issue UL-MAP and DL-MAP messages referring to it. When transitioning from one generation to the next, the BS shall schedule the transmissions of the UCD and DCD messages in such a way that each terminal has the possibility to hear it at least once.

[DCD transition interval start]
6.3.12 Assigning SSs to multicast groups

The BS may add an SS to a multicast polling group by sending an MCA-REQ message with the Join command. Upon receiving an MCA-REQ message, the SS shall respond by sending an MCA-RSP message. The protocol is shown in Figure 103 and Figure 104.
Figure 103—Multicast polling assignment—SS
Figure 104—Multicast polling assignment—BS
6.3.13 Establishment of multicast connections

The BS may establish a DL multicast and broadcast service by creating a multicast connection with each SS to be associated with the service. Any available traffic CID value may be used for the service (i.e., there are no dedicated CIDs for multicast transport connections). To ensure proper multicast operation, the CID used for the service is the same for all SSs on the same channel that participate in the connection. The SSs need not be aware that the connection is a multicast connection. However, for multicast and broadcast services which utilize MBS specific features, the multicast connection shall be established using a multicast CID.

The data transmitted on the connection with the given CID shall be received and processed by the MAC of each involved SS. Thus, each multicast or broadcast SDU is transmitted only once per BS channel. Since a multicast connection is associated with a service flow, it is associated with the QoS and traffic parameters for that service flow.

ARQ is not applicable to multicast connections.

If a DL multicast connection is to be encrypted, each SS participating in the connection shall have an additional security association (SA), allowing that connection to be encrypted using keys that are independent of those used for other encrypted transmissions between the SSs and the BS.

6.3.14 Quality of service (QoS)

This standard defines several QoS-related concepts. These include the following:

a) Service flow QoS scheduling
b) Dynamic service establishment
c) Two-phase activation model

6.3.14.1 Theory of operation

The various protocol mechanisms described in this document may be used to support QoS for both UL and DL traffic through the SS and the BS. This subclause provides an overview of the QoS protocol mechanisms and their part in providing end-to-end QoS.

The requirements for QoS include the following:

a) A configuration and registration function for preconfiguring SS-based QoS service flows and traffic parameters.
b) A signaling function for dynamically establishing QoS-enabled service flows and traffic parameters.
c) Utilization of MAC scheduling and QoS traffic parameters for UL service flows.
d) Utilization of QoS traffic parameters for DL service flows.
e) Grouping of service flow properties into named service classes, so upper-layer entities and external applications (at both the SS and BS) may request service flows with desired QoS parameters in a globally consistent way.

The principal mechanism for providing QoS is to associate packets traversing the MAC interface into a service flow as identified by the Transport CID. A service flow is a unidirectional flow of packets that is provided a particular QoS. The SS and BS provide this QoS according to the QoS parameter set defined for the service flow.

The primary purpose of the QoS features defined here is to define transmission ordering and scheduling on the air interface. However, these features often need to work in conjunction with mechanisms beyond the air interface in order to provide end-to-end QoS or to police the behavior of SSs.
Service flows exist in both the UL and DL direction and may exist without actually being activated to carry traffic. All service flows have a 32-bit SFID; admitted and active service flows also have a 16-bit CID.

### 6.3.14.2 Service flows

A service flow is a MAC transport service that provides unidirectional transport of packets either to UL packets transmitted by the SS or to DL packets transmitted by the BS.\textsuperscript{16} A service flow is characterized by a set of QoS parameters such as latency, jitter, and throughput assurances. In order to standardize operation between the SS and BS, these attributes include details of how the SS requests UL bandwidth allocations and the expected behavior of the BS UL scheduler.

A service flow is partially characterized by the following attributes:\textsuperscript{17}

a) **Service Flow ID**: An SFID is assigned to each existing service flow. The SFID serves as the principal identifier for the service flow in the subscriber station. A service flow has at least an SFID and an associated direction.

b) **CID**: The connection identifier of the transport connection exists only when the service flow is admitted or active. The relationship between SFID and Transport CID, when present, is unique. An SFID shall never be associated with more than one Transport CID, and a Transport CID shall never be associated with more than one SFID.

c) **ProvisionedQoSParamSet**: A QoS parameter set provisioned via means outside of the scope of this standard, such as the network management system.

d) **AdmittedQoSParamSet**: Defines a set of QoS parameters for which the BS (and possibly the SS) are reserving resources. The principal resource to be reserved is bandwidth, but this also includes any other memory or time-based resource required to subsequently activate the flow.

e) **ActiveQoSParamSet**: Defines a set of QoS parameters defining the service actually being provided to the service flow. Only an active service flow may forward packets.

f) **Authorization Module**: A logical function within the BS that approves or denies every change to QoS parameters and classifiers associated with a service flow. As such, it defines an “envelope” that limits the possible values of the AdmittedQoSParamSet and ActiveQoSParamSet.

The relationship between the QoS parameter sets is as shown in Figure 105 and Figure 106. The ActiveQoSParamSet is always a subset\textsuperscript{18} of the AdmittedQoSParamSet, which is always a subset of the authorized “envelope.” In the dynamic authorization model, this envelope is determined by the Authorization Module (labeled as the AuthorizedQoSParamSet). In the provisioned authorization model, this envelope is determined by the ProvisionedQoSParamSet. It is useful to think of three types of service flows:

1) **Provisioned**: This type of service flow is known via provisioning by, for example, the network management system. Its AdmittedQoSParamSet and ActiveQoSParamSet are both null.

\textsuperscript{16}A service flow, as defined here, has no direct relationship to the concept of a “flow” as defined by the IETF Integrated Services (intserv) Working Group (IETF RFC 2212). An intserv flow is a collection of packets sharing transport-layer endpoints. Multiple intserv flows can be served by a single service flow.

\textsuperscript{17}Some attributes are derived from the above attribute list. The service class name is an attribute of the ProvisionedQoSParamSet. The activation state of the service flow is determined by the ActiveQoSParamSet. If the ActiveQoSParamSet is null, then the service flow is inactive.

\textsuperscript{18}To say that QoS parameter set A is a subset of QoS parameter set B the following shall be true for all QoS parameters in A and B: if (a smaller QoS parameter value indicates less resources, e.g., Maximum Traffic Rate) A is a subset of B if the parameter in A is less than or equal to the same parameter in B if (a larger QoS parameter value indicates less resources, e.g., Tolerated Grant Jitter) A is a subset of B if the parameter in A is greater than or equal to the same parameter in B if (the QoS parameter is not quantitative) A is a subset of B if the parameter in A is equal to the same parameter in B
AuthorizedQoSParamSet = ProvisionedQoSParamSet (SFID)

AdmittedQoSParamSet (SFID & CID)

ActiveQoSParamSet (SFID & active CID)

AuthorizedQoSParamSet (BS only, not known by SS)

AdmittedQoSParamSet (SFID & CID)

ActiveQoSParamSet (SFID & active CID)
2) **Admitted**: This type of service flow has resources reserved by the BS for its AdmittedQoSParamSet, but these parameters are not active (i.e., its ActiveQoSParamSet is null). Admitted service flows may have been provisioned or may have been signalled by some other mechanism.

3) **Active**: This type of service flow has resources committed by the BS for its ActiveQoSParamSet, (e.g., is actively sending maps containing unsolicited grants for a UGS-based service flow). Its ActiveQoSParamSet is non-null.

### 6.3.14.3 Object model

The major objects of the architecture are represented by named rectangles in Figure 107. Each object has a number of attributes; the attribute names that uniquely identify it are underlined. Optional attributes are denoted with brackets. The relationship between the number of objects is marked at each end of the association line between the objects. For example, a service flow may be associated with from 0 to \(N\) (many) PDUs, but a PDU is associated with exactly one service flow. The service flow is the central concept of the MAC protocol. In the subscriber station, it is uniquely identified by a 32-bit (SFID). Service flows may be in either the UL or DL direction. There is a one-to-one mapping between admitted and active service flows (32-bit SFID) and transport connections (16-bit CID).

![Figure 107—Theory of Operation Object Model](image)

Outgoing user data is submitted to the MAC SAP by a CS process for transmission on the MAC interface. The information delivered to the MAC SAP includes the CID identifying the transport connection across which the information is delivered. The service flow for the connection is mapped to MAC transport connection identified by the CID.
A Classifier Rule uniquely maps a packet to its transport connection. The Classifier Rule is associated to zero or one PHS Rules. When creating a PHS Rule the associated Classifier Rule Index is used as a reference. A PHS Rule is associated to a single service flow. PHS Rules associated to the same service flow are uniquely identified by their PHSI. The Classifier Rule uniquely maps packets to its associated PHS Rule.

The service class is an optional object that may be implemented at the BS. It is referenced by an ASCII name, which is intended for provisioning purposes. A service class is defined in the BS to have a particular QoS parameter set. The QoS parameter sets of a service flow may contain a reference to the service class name as a “macro” that selects all of the QoS parameters of the service class. The service flow QoS parameter sets may augment and even override the QoS parameter settings of the service class, subject to authorization by the BS.

6.3.14.4 Service classes

The service class serves the following purposes:

a) It allows operators, who so wish, to move the burden of configuring service flows from the provisioning server to the BS. Operators provision the SSs with the service class name; the implementation of the name is configured at the BS. This allows operators to modify the implementation of a given service to local circumstances without changing SS provisioning. For example, some scheduling parameters may need to be tweaked differently for two different BSs to provide the same service. As another example, service profiles could be changed by time of day.

b) It allows higher layer protocols to create a service flow by its service class name. For example, telephony signaling may direct the SS to instantiate any available provisioned service flow of class “G711.”

NOTE—Service classes are merely IDs for a specific set of QoS parameter set values. Hence, the use of service classes is optional. A service identified by a service class is treated no differently, once established, than a service that has the same QoS parameter set explicitly specified.

Any service flow may have its QoS parameter set specified in any of the following three ways:

— By explicitly including all traffic parameters.
— By indirectly referring to a set of traffic parameters by specifying a service class name.
— By specifying a service class name along with modifying parameters.

The service class name is “expanded” to its defined set of parameters at the time the BS successfully admits the service flow. The service class expansion can be contained in the following BS-originated messages: DSA-REQ, DSC-REQ, DSA-RSP, and DSC-RSP. In all of these cases, the BS shall include a service flow encoding that includes the service class name and the QoS parameter set of the service class. If an SS-initiated request contained any supplemental or overriding service flow parameters, a successful response shall also include these parameters.

When a service class name is given in an admission or activation request, it is possible that the returned QoS parameter set may change from activation to activation. This can happen because of administrative changes to the service class’s QoS parameter set at the BS. If the definition of a service class name is changed at the BS (e.g., its associated QoS parameter set is modified), it has no effect on the QoS parameters of existing service flows associated with that service class. A BS may initiate DSC transactions to existing service flows that reference the service class name to affect the changed service class definition.

When an SS uses the service class name to specify the admitted QoS parameter set, the expanded set of TLV encodings of the service flow shall be returned to the SS in the response message (DSA-RSP or DSC-RSP). Use of the service class name later in the activation request may fail if the definition of the service class name has changed and the new required resources are not available. Thus, the SS should explicitly request the expanded set of TLVs from the response message in its later activation request.
6.3.14.4.1 Global service classes

Networks require common definitions of service class names and associated AuthorizedQoSParamSets in order to facilitate operation across a distributed topology. Global service class names shall be supported to enable operation in this context.

In operation, global service class names are employed as a baseline convention for communicating AuthorizedQoSParamSet or AdmittedQoSParamSet. Global service class name is similar in function to service class name except that

— Global service class name use may not be modified by a BS.
— Global service class names remain consistent among all BS.
— Global service class names are a rules-based naming system whereby the global service class name itself contains referential QoS parameter codes.

In practice, global service class names are intended to be accompanied by extending or modifying QoS Param Set defining parameters, as needed, to provide a complete and expedited method for transferring AuthorizedQoSParamSet or AdmittedQoSParamSet information.

Global service class name is a rules-based, composite name parsed in a variable number of information fields of format,

for $I=1$, format is ISBRLSPS1R and length is five bytes;
for $I=0$ and $S2=0$ or 1, format is ISBRLSPS1S2R and length is five bytes;

The global service class name parameters are as follows:

**Uplink/Downlink Indicator**

The Uplink/Downlink Indicator parameter identifies the defined service flow direction from the originating entity.

**Maximum Sustained Traffic Rate**

A parameter that defines the peak information rate of the service. The rate is expressed in bits per second and pertains to the service data units (SDUs) at the input to the system. Explicitly, this parameter does not include transport, protocol, or network overhead such as MAC headers or CRCs, or nonpayload session maintenance overhead like SIP, MGCP, H.323 administration, etc. This parameter does not limit the instantaneous rate of the service since this is governed by the physical attributes of the ingress port. However, at the destination network interface in the UL direction, the service shall be policed to conform to this parameter, on the average, over time. On the network in the DL direction, it may be assumed that the service was already policed at the ingress to the network. If this parameter is set to zero, then there is no explicitly mandated maximum rate. The maximum sustained traffic rate field specifies only a bound, not a determination of the actual rate.

### Maximum traffic burst

The Maximum traffic burst parameter defines the maximum burst size that shall be accommodated for the service. Since the physical speed of ingress/egress ports, any air interface, and the backhaul will in general be greater than the maximum sustained traffic rate parameter for a service, this parameter describes the maximum continuous burst the system should accommodate for the service assuming the service is not currently using any of its available resources. Maximum traffic burst set to zero shall mean no Maximum traffic burst reservation requirement.

### Minimum reserved traffic rate

The Minimum reserved traffic rate parameter specifies the minimum rate, in bits per second, reserved for this service flow. The BS shall be able to satisfy BRs for a connection up to its minimum reserved traffic rate. If less bandwidth than its Minimum reserved traffic rate is requested for a connection, the BS may reallocate the excess reserved bandwidth for other purposes. The value of this parameter is calculated excluding MAC overhead. Minimum reserved traffic set to zero shall mean no minimum reserved traffic rate requirement.
Maximum latency

The value of this parameter specifies the maximum interval between the reception of a packet at the CS of the BS or the SS and the forwarding of the SDU to its Air Interface. If defined, this parameter represents a service commitment and shall be guaranteed. A value of zero for Maximum latency shall be interpreted as no commitment. See Table 188.

</tbody>
</table>

SDU indicator

The value of this parameter specifies whether the SDUs on the service flow are fixed-length or variable-length.

Paging Preference

This parameter is a single bit indicator of an MS’s preference for the reception of paging advisory messages during idle mode. When set, it indicates that the BS may present paging advisory messages or other indicative messages to the MS when data SDUs bound for the MS are present while the MS is in idle mode.

Uplink Grant Scheduling Type

This parameter specifies which Uplink grant scheduling service type is associated with uplink service flow (Refer to 11.13.10). This parameter is available in case of UL service flow with Uplink/Downlink indicator = 0 (i.e., uplink). Otherwise, it shall be set to ‘000’ as no commitment.

Tolerated Jitter

The value of this parameter specifies the maximum delay variation (jitter) for the connection. This parameter is available in case of a DL or UL service flow, which are associated with Uplink Grant Scheduling Type = UGS or erTPS. Otherwise, it shall be set to ‘000000’ as no commitment. If defined, this parameter represents a service commitment and shall be guaranteed. A value of zero for Maximum latency shall be interpreted as no commitment. (Refer to Table 188 and 11.13.12.)

Request/Transmission Policy

The value of this parameter specifies a certain attributes for the associated service flow. Each bit specifies each other action. (Refer to 11.13.11.)
Traffic Priority
The value of this parameter specifies the priority of associated service flow (refer to 11.13.5). This parameter is available in case of a DL or UL service flow, which are associated with any other Uplink Grant Scheduling Types except UGS.

Unsolicited Grant Interval
This parameter defines the nominal interval between successive data grant opportunities for a DL service flow, which are associated with Uplink Grant Scheduling Type = UGS or ertPS (refer to the Table 189 and 11.13.19). If this parameter is set to zero, then there is no explicitly mandated unsolicited grant interval. The maximum unsolicited grant interval field specifies only a bound, not a guarantee that the rate is available. The algorithm for policing this parameter is left to vendor differentiation and is outside the scope of the standard.

Unsolicited Polling Intervals
This parameter defines the maximal nominal interval between successive polling grants opportunities for a UL service flow, which are associated with Uplink Grant Scheduling Type = rtPS (refer to the Table 189 and 11.13.20). If this parameter is set to zero, then there is no explicitly mandated unsolicited grant interval. The maximum unsolicited polling interval field specifies only a bound, not a guarantee that the rate is available. The algorithm for policing this parameter is left to vendor differentiation and is outside the scope of the standard.

</table>
6.3.14.5 Authorization

Every change to the service flow QoS parameters shall be approved by an authorization module. This includes every DSA-REQ message to create a new service flow and every DSC-REQ message to change a QoS parameter set of an existing service flow. Such changes include requesting an admission control decision (e.g., setting the AdmittedQoSParamSet) and requesting activation of a service flow (e.g., setting the ActiveQoSParamSet). Reduction requests regarding the resources to be admitted or activated are also checked by the authorization module.

In the static authorization model, the authorization module stores the provisioned status of all “deferred” service flows. Admission and activation requests for these provisioned service flows shall be permitted, as long as the admitted QoS parameter set is a subset of the provisioned QoS parameter set, and the active QoS parameter set is a subset of the admitted QoS parameter set. Requests to change the provisioned QoS parameter set shall be refused, as shall requests to create new dynamic service flows. This defines a static system where all possible services are defined in the initial configuration of each SS.

In the dynamic authorization model, the authorization module also communicates through a separate interface to an independent policy server. This policy server may provide the authorization module with advance notice of upcoming admission and activation requests, and it specifies the proper authorization action to be taken on those requests. Admission and activation requests from an SS are then checked by the Authorization Module to ensure that the ActiveQoSParamSet being requested is a subset of the set provided by the policy server. Admission and activation requests from an SS that are signalled in advance by the external policy server are permitted. Admission and activation requests from an SS that are not presignalled by the external policy server may result in a real-time query to the policy server or may be refused.

Prior to initial connection setup, the BS shall retrieve the provisioned QoS parameter set for an SS. This is handed to the Authorization Module within the BS. The BS shall be capable of caching the provisioned QoS parameter set and shall be able to use this information to authorize dynamic flows that are a subset of the provisioned QoS parameter set. The BS should implement mechanisms for overriding this automated approval process (such as described in the dynamic authorization model). For example it could

a) Deny all requests regardless of whether they have been preprovisioned.

b) Define an internal table with a richer policy mechanism but seeded by the Provisioned QoS Set.

c) Refer all requests to an external policy server.

6.3.14.6 Types of service flows

It is useful to think about three basic types of service flows. This subclause describes these three types of service flows in more detail. However, it is important to note that there are more than just these three basic types (see 11.13.4).

6.3.14.6.1 Provisioned service flows

A service flow may be provisioned but not immediately activated (sometimes called “deferred”). In other words, the description of any such service flow contains an attribute that provisions but defers activation and admission (see 11.13.4). The network assigns a SFID for such a service flow. The BS may also require an exchange with a policy module prior to admission.

As a result of external action beyond the scope of this specification, the SS may choose to activate a provisioned service flow by passing the SFID and the associated QoS parameter sets to the BS in the DSC-REQ message. If authorized and resources are available, the BS shall respond by mapping the service flow to a CID.
As a result of external action beyond the scope of this specification, the BS may choose to activate a service flow by passing the SFID as well as the CID and the associated QoS parameter sets to the SS in the DSC-REQ message. Such a provisioned service flow may be activated and deactivated many times (through DSC exchanges). In all cases, the original SFID shall be used when reactivating the service flow.

6.3.14.6.2 Admitted service flows

This protocol supports a two-phase activation model that is often utilized in telephony applications. In the two-phase activation model, the resources for a “call” are first “admitted,” and then once the end-to-end negotiation is completed (e.g., called party’s gateway generates an “off-hook” event), the resources are “activated.” The two-phase model serves the following purposes:

1) Conserving network resources until a complete end-to-end connection has been established,
2) Performing policy checks and admission control on resources as quickly as possible, and in particular, before informing the far end of a connection request, and
3) Preventing several potential theft-of-service scenarios.

For example, if an upper-layer service were using UGS, and the addition of upper-layer flows could be adequately provided by increasing the Maximum Sustained Traffic Rate QoS parameter, then the following procedure might be used. When the first higher layer flow is pending, the SS issues a DSA-REQ with the admitted Maximum Sustained Traffic Rate parameter equal to that required for one higher layer flow, and the active Maximum Sustained Traffic Rate parameter equal to zero. Later when the higher layer flow becomes active, it issues a DSC-REQ with the instance of the active Maximum Sustained Traffic Rate parameter equal to that required for one higher layer flow. Admission control was performed at the time of the reservation, so the later DSC-REQ, having the active parameters within the range of the previous reservation, is guaranteed to succeed. Subsequent higher layer flows would be handled in the same way. If there were three higher layer flows establishing connections, with one flow already active, the service flow would have admitted Maximum Sustained Traffic Rate equal to that required for four higher layer flows, and active Maximum Sustained Traffic Rate equal to that required for one higher layer flow.

An activation request of a service flow where the new ActiveQoSParamSet is a subset of the AdmittedQoSParamSet shall be allowed, except in the case of catastrophic failure. An admission request where the AdmittedQoSParamSet is a subset of the previous AdmittedQoSParamSet, so long as the ActiveQoSParamSet remains a subset of the AdmittedQoSParamSet, shall succeed.

A service flow that has resources assigned to its AdmittedQoSParamSet, but whose resources are not yet completely activated, is in a transient state. It is possible in some applications that a long-term reservation of resources is necessary or desirable. For example, placing a telephone call on hold should allow any resources in use for the call to be temporarily allocated to other purposes, but these resources shall be available for resumption of the call later. The AdmittedQoSParamSet is maintained as “soft state” in the BS; this state shall be maintained without releasing the nonactivated resources. Changes may be signaled with a DSC-REQ message.

6.3.14.6.3 Active service flows

A service flow that has a non-NULL ActiveQoSParamSet is said to be an active service flow. It is requesting (according to its Request/Transmission Policy, as in 11.13.11) and being granted bandwidth for transport of data packets. An admitted service flow may be activated by providing an ActiveQoSParamSet, signaling the resources actually desired at the current time. This completes the second stage of the two-phase activation model (see 6.3.14.6.2).

A service flow may be provisioned and immediately activated. Alternatively, a service flow may be created dynamically and immediately activated. In this case, two-phase activation is skipped and the service flow is available for immediate use upon authorization.
6.3.14.7 Service flow creation

The provisioning of service flows is done via means outside of the scope of this standard, such as the network management system. During provisioning, a service flow is instantiated, gets a SFID and a “provisioned” type. For some service flows it may be specified that DSA procedure shall be activated by Network Entry procedure. Enabling service flows follows the transfer of the operational parameters, as shown in Figure 65. In this case, the service flow type may change to “admitted” or to “active.” Thus, the service flow is mapped onto a certain connection.

Service flow encodings contain either a full definition of service attributes (omitting defaultable items if desired) or a service class name. A service class name is an ASCII string, which is known at the BS and which indirectly specifies a set of QoS parameters.

Triggers, other than network entry, also may cause creation, admission, or activation of service flows. Such triggers lay outside the scope of the standard.

Capability of handling each specific service flow parameter is optional.

6.3.14.7.1 Dynamic service flow creation

6.3.14.7.1.1 Dynamic service flow creation—SS-initiated

Creation of service flows may be initiated by either BS (mandatory capability) or by SS (optional capability).

The SS-initiated protocol is illustrated in Figure 108 and described in detail in 6.3.14.9.3.1.

A DSA-REQ from an SS contains a QoS parameter set (marked either for admission-only or for admission and activation).

BS responds with a DSA-RSP indicating acceptance or rejection. In the case when rejection was caused by presence of a nonsupported parameter of nonsupported value, specific parameter may be included into DSA-RSP. If the BS rejects a service flow due to absence of sufficient resources to admit the service flow (see Table 607, CC = 3), the BS may initiate procedures to move the SS to a different BS (see 6.3.21).

![DSA message flow—SS-initiated](image-url)
6.3.14.7.1.2 Dynamic service flow creation—BS-initiated

A DSA-REQ from a BS contains an SFID for either one UL or one DL service flow, possibly its associated CID, and a set of active or admitted QoS parameters. The protocol is illustrated in Figure 109 and is described in detail in 6.3.14.9.3.3.

SS responds with DSA-RSP indicating acceptance or rejection. In the case when rejection was caused by presence of nonsupported parameter of nonsupported value, specific parameter may be included into DSA-RSP.

![DSA message flow—BS-initiated](image)

6.3.14.8 Dynamic service flow modification and deletion

In addition to the methods presented in 6.3.14.7 for creating service flows, protocols are defined for modifying and deleting service flows; see 6.3.14.9.4 and 6.3.14.9.5.

Both provisioned and dynamically created service flows are modified with the DSC message, which can change the admitted and active QoS parameter sets of the flow.

A successful DSC transaction changes a service flow’s QoS parameters by replacing both the admitted and active QoS parameter sets. If the message contains only the admitted set, the active set is set to null and the flow is deactivated. If the message contains neither set (“000” value used for QoS parameter set type, see 11.13.4), then both sets are set to null and the flow is de-admitted. When the message contains both QoS parameter sets, the admitted set is checked first, and if admission control succeeds, the active set in the message is checked against the admitted set in the message to ensure that it is a subset. If all checks are successful, the QoS parameter sets in the message become the new admitted and active QoS parameter sets for the service flow. If either of the checks fails, the DSC transaction fails and the service flow QoS parameter sets are unchanged.

6.3.14.9 Service flow management

6.3.14.9.1 Overview

Service flows may be created, changed, or deleted. This is accomplished through a series of MAC management messages referred to as DSA, DSC, and DSD. The DSA messages create a new service flow.
The DSC messages change an existing service flow. The DSD messages delete an existing service flow. This is illustrated in Figure 110.

![Dynamic service flow overview](image)

The Null state implies that no service flow exists that matches the SFID and/or Transaction ID in a message. Once the service flow exists, it is operational and has an assigned SFID. In steady-state operation, a service flow resides in a Nominal state. When DSx messaging is occurring, the service flow may transition through other states, but remains operational. Since multiple service flows may exist, there may be multiple state machines active, one for every service flow. DSx messages only affect those state machines that match the SFID and/or Transaction ID. Both the SS and BS shall verify the HMAC-Digest on all DSx messages before processing them, and discard any messages that fail.

Transaction IDs are unique per transaction and are selected by the initiating device (SS or BS). To help prevent ambiguity and provide simple checking, the Transaction ID number space is split between the SS and BS. The SS shall select its Transaction IDs from the first half of the number space (0x0000 to 0x7FFF). The BS shall select its Transaction IDs from the second half of the number space (0x8000 to 0xFFFF).

Each DSx message sequence is a unique transaction with an associated unique transaction ID. The DSA/DSC transactions consist of a request/response/acknowledge sequence. The DSD transactions consist of a request/response sequence. The response messages shall return a CC of OK unless some exception condition was detected. The acknowledge messages shall return the CC in the response unless a new exception condition arises. A more detailed state diagram, including transition states, is shown in Figure 111 through Figure 117. The detailed actions for each transaction shall be given in the following subclauses.

**6.3.14.9.2 Dynamic service flow state transitions**

The Dynamic Service Flow state transition diagram (Figure 111) is the top-level state diagram and controls the general service flow state. As needed, it creates transactions, each represented by a Transaction state transition diagram, to provide the DSA, DSC, and DSD signaling. Each Transaction state transition diagram communicates only with the parent Dynamic Service Flow state transition diagram. The top-level state transition diagram filters DSx messages and passes them to the appropriate transaction based on SFID and Transaction ID.

There are six different types of transactions, which are locally initiated or remotely initiated for each of the DSA, DSC, and DSD messages (Figure 112 through Figure 117). Most transactions have three basic states—pending, holding, and deleting. The pending state is typically entered after creation and is where the transaction is waiting for a reply. The holding state is typically entered once the reply is received. The purpose of this state is to allow for retransmissions in case of a lost message, even though the local entity has perceived that the transaction has completed. The deleting state is only entered if the service flow is being deleted while a transaction is being processed.
The flow diagrams provide a detailed representation of each of the states in the Transaction state transition diagrams. All valid transitions are shown. Any inputs not shown should be handled as a severe error condition.

With one exception, these state diagrams apply equally to the BS and SS. In the Dynamic Service Flow Changing-Local state, there is a subtle difference in the SS and BS behaviors. This is called out in the state transition and detailed flow diagrams.

NOTE—The “Num Xacts” variable in the Dynamic Service Flow state transition diagram is incremented every time the top-level state diagram creates a transaction and is decremented every time a transaction terminates. A dynamic service flow shall not return to the Null state until it is deleted and all transactions have terminated.

The inputs for the state diagrams are identified below.

Dynamic Service Flow state transition diagram inputs from unspecified local, higher level entities:
- Add
- Change
- Delete

Dynamic Service Flow state transition diagram inputs from DSx Transaction state transition diagrams:
- DSA Succeeded
- DSA Failed
- DSA-ACK Lost
- DSA Erred
- DSA Ended

- DSC Succeeded
- DSC Failed
- DSC-ACK Lost
- DSC Erred
- DSC Ended

- DSD Succeeded
- DSD Erred
- DSD Ended

DSx Transaction state transition diagram outputs from the Dynamic Service Flow state transition diagram:
- SF Add
- SF Change
- SF Delete

- SF Abort Add
- SF Change-Remote
- SF Delete-Local
- SF Delete-Remote

- SF DSA-ACK Lost
- SF DSC-REQ Lost
- SF DSC-ACK Lost
- SF DSD-REQ Lost

- SF Changed
- SF Deleted
The creation of DSx transactions by the Dynamic Service Flow state transition diagram is indicated by the notation:

\[
\text{DSx} \rightarrow [\text{Local} \mid \text{Remote}] (\text{initial}_\text{input})
\]

where initial_input may be SF Add, DSA-REQ, SF Change, DSC-REQ, SF Delete, or DSD-REQ, depending on the transaction type and initiator.

State transitions (i.e., the lines between states) are labeled with <what causes the transition>/<messages and events triggered by the transition>. If there are multiple events or messages before the slash “/” separated by a comma, any of them can cause the transition. If there are multiple events or messages listed after the slash, all of the specified actions shall accompany the transition.

For example, “DSD-REQ/SF Delete Remote, DSD-Remote(DSD-REQ)” should be read as follows: Once DSD-REQ is received, it triggers sending a “SF Delete Remote” event to transactions running for this service flow AND starting the “DSD-Remote” transaction and pass the event DSD-REQ to it.

6.3.14.9.3 Dynamic service addition (DSA)

6.3.14.9.3.1 SS-initiated DSA

An SS wishing to create either an UL or DL service flow sends a request to the BS using a DSA-REQ message. The BS checks the integrity of the message and, if the message is intact, sends a message received (DSX-RVD) response to the SS. The BS checks the SS’s authorization for the requested service and whether the QoS requirements can be supported, generating an appropriate response using a DSA-RSP message. The SS concludes the transaction with an acknowledgment message (DSA-ACK). This process is illustrated in Table 190.

6.3.14.9.3.2 BS-initiated DSA

A BS wishing to establish either an UL or a DL dynamic service flow with an SS performs the following operations. The BS checks the authorization of the destination SS for the requested class of service and to determine whether the QoS requirements can be supported. If the service can be supported, the BS generates a new SFID with the required class of service and informs the SS using a DSA-REQ message. If the SS checks that it can support the service, it responds using a DSA-RSP message. The transaction completes with the BS sending the acknowledge message (DSA-ACK). This process is illustrated in Table 191.

Table 190—DSA initiated from SS (continued)

</tbody>
</table>

Authorization happens prior to the DSA-REQ being received by the BS. The details of BS signalling to anticipate a DSA-REQ are beyond the scope of this standard.

6.3.14.9.4 Dynamic service change (DSC)

The DSC set of messages is used to modify the flow parameters associated with a service flow. Specifically, DSC can modify the service flow specification. Implementation of dynamic service change initiated by BS is mandatory. Implementation of dynamic service change initiated by SS is optional.

A single DSC message exchange can modify the parameters of either one DL service flow or one UL service flow.

To prevent packet loss, any required bandwidth change is sequenced between the SS and BS.

The BS controls both UL and DL scheduling. The timing of scheduling changes is independent of direction AND whether it is an increase or decrease in bandwidth. The BS always changes scheduling on receipt of a DSC-REQ (SS-initiated transaction) or DSC-RSP (BS-initiated transaction).

The BS also controls the DL Tx behavior. The change in DL Tx behavior is always coincident with the change in DL scheduling (i.e., BS controls both and changes both simultaneously).

The SS controls the UL Tx behavior. The timing of SS Tx behavior changes is a function of which device initiated the transaction AND whether the change is an “increase” or “decrease” in bandwidth.

If an UL service flow’s bandwidth is being reduced, the SS reduces its payload bandwidth first and then the BS reduces the bandwidth scheduled for the service flow. If an UL service flow’s bandwidth is being increased, the BS increases the bandwidth scheduled for the service flow first and then the SS increases its payload bandwidth.

Any service flow can be deactivated with a DSC command by sending a DSC-REQ message, referencing the SFID, and including a null ActiveQoSParamSet. If a service flow that was provisioned is deactivated, the provisioning information for that service flow shall be maintained until the service flow is reactivated.

An SS shall have only one DSC transaction outstanding per service flow. If it detects a second transaction initiated by the BS, the SS shall abort the transaction it initiated and allow the BS-initiated transaction to complete.

A BS shall have only one DSC transaction outstanding per service flow. If it detects a second transaction initiated by the SS, the BS shall abort the transaction that the SS initiated and allow the BS-initiated transaction to complete.

The following service flow parameters may not be changed and shall not be present in the DSC-REQ or DSC-RSP messages:

- Service Flow Scheduling Type
- Type of Data Delivery Services
- Request/Transmission Policy
- Convergence Sublayer Specification
- Fixed-Length versus Variable-Length SDU Indicator
- SDU Size
- ATM switching (ATM Services only)
- ARQ parameters, in accordance with individual TLV definitions
- FSN Size
- Target SAIID
NOTE—Currently anticipated applications would probably control a service flow through either the SS or BS, and not both. Therefore, the case of a DSC being initiated simultaneously by the SS and BS is considered as an exception condition and treated as one.

### 6.3.14.9.4.1 SS-initiated DSC

An SS that needs to change a service flow definition performs the following operations.

The SS informs the BS using a DSC-REQ. The BS checks the integrity of the message and, if the message is intact, sends a message received (DSX-RVD) response to the SS. The BS shall decide if the referenced service flow can support this modification. The BS shall respond with a DSC-RSP indicating acceptance or rejection. In the case when rejection was caused by presence of nonsupported parameter of nonsupported value, specific parameter may be included into DSC-RSP. The SS reconfigures the service flow if appropriate, and then shall respond with a DSC-ACK. This process is illustrated in Table 192.

<table>

</tr>
</tbody>
</table>

### 6.3.14.9.4.2 BS-initiated DSC

A BS that needs to change a service flow definition performs the following operations.

The BS shall decide if the referenced service flow can support this modification. If so, the BS informs the SS using a DSC-REQ. The SS checks that it can support the service change, and shall respond using a DSC-RSP indicating acceptance or rejection. In the case when rejection was caused by presence of nonsupported parameter of nonsupported value, specific parameter may be included into DSC-RSP. The BS reconfigures the service flow if appropriate, and then shall respond with a DSC-ACK. This process is illustrated in Table 193.

Figure 135—DSC—Remotely Initiated Transaction Deleting Service Flow state flow diagram
6.3.14.9.5 Connection release

Any service flow can be deleted with the DSD messages. When a service flow is deleted, all resources associated with it are released. If a service flow for a provisioned service is deleted, the ability to reestablish the service flow for that service is network management dependent. Therefore, care should be taken before deleting such service flows. Implementation of dynamic Service deletion initiated by BS is mandatory. Implementation of dynamic service deletion initiated by SS is optional.

6.3.14.9.5.1 SS-initiated DSD

An SS wishing to delete a service flow generates a delete request to the BS using a DSD-REQ message. The BS removes the service flow and generates a response using a DSD-RSP message. This process is illustrated in Table 194. Only one service flow can be deleted per DSD-REQ.

<table>
<thead>
<tr>
<th>SS</th>
<th>BS</th>
</tr>
</thead>
<tbody>
<tr>

6.3.15 Procedures for shared frequency band usage

6.3.15.1 Introduction

Procedures are defined in this subclause that may be used when the IEEE 802.16 system is sharing a frequency band with another system or service to reduce interference to and from other systems, to facilitate coexistence of systems, or to address other reasons. These procedures generally involve mechanisms to facilitate the detection of other users and to avoid and prevent harmful interference into other users. Within these procedures for certain sharing scenarios, regulatory requirements specify that DFS (as defined by ITU Recommendation M.1652 [B35]) shall be used to facilitate sharing with specific spectrum users identified by regulation. A specific spectrum user is a user from a service specifically identified by regulation as requiring protection from harmful interference. When DFS is mandated by regulatory requirements, it shall be implemented according to this specification.

Further, the use of a channel selection algorithm may be required, which results in uniform channel spreading across a minimum number of channels. This specification is intended to be compliant with regulatory requirements such as ERC/DEC/(99)23 [B10]. The timing and threshold parameters used for DFS are specified by each regulatory administration.

The procedures specified in this subclause provide for the following:

- Testing channels for other users including specific spectrum users (6.3.15.2)
- Discontinuing operations after detecting other users including specific spectrum users (6.3.15.3)
- Detecting other users including specific spectrum users (6.3.15.4)
- Scheduling for channel testing (6.3.15.5)
- Requesting and reporting of measurements (6.3.15.6)
- Selecting and advertising a new channel (6.3.15.7)
6.3.15.2 Testing channels for other users (including specific spectrum users)

A BS or SS implementing these procedures shall not use a channel that it knows contains other users or has not been tested recently for the presence of other users. A BS shall test for the presence of other users based on timing parameters and values that may be set locally or, in the case of DFS and the detection of specific spectrum users, may be defined in regulation. Timing parameters include the following:

- **Startup Test Period** before operating in a new channel if the channel has not been tested for other users for at least **Startup Test Period** during the last **Startup Test Valid**.
- **Startup Test Period** before operating in a new channel if a channel was previously determined to contain other users during the last **Startup Test Valid**.
- **Operating Test Period** (where the period is only accumulated during testing) of each **Operating Test Cycle** while operating in a channel. Testing may occur in quiet periods or during normal operation.

An SS may start operating in a new channel without following the above start-up testing procedures if

- The SS moves to the channel as a result of the receipt of a Channel Switch Announcement from the BS.
- The SS is initializing with a BS that is not currently advertising, using the Channel Switch Announcement, that it is about to move to a new channel.

A BS may start operating in a new channel without following the above start-up testing procedures if it has learned from another device by means outside the scope of this standard that it is usable.

6.3.15.3 Discontinuing operations after detecting specific spectrum users

If a BS or an SS is operating in a channel and detects specific spectrum users, it shall discontinue any transmission of the following:

- MAC PDUs carrying data within **Max Data Operations Period**.
- MAC PDUs carrying MAC management messages within **Management Operations Period**.

The values of the above parameters may be set locally or, in the case of DFS, may be defined in regulation.

6.3.15.4 Detecting specific spectrum users

Each BS and SS shall use a method to detect specific spectrum users operating in a channel that satisfies the regulatory requirements, where applicable. The particular method used to perform detection is outside the scope of this standard.

6.3.15.5 Scheduling for channel testing

A BS may measure one or more channels itself and may request any SS to measure one or more channels on its behalf, either in a quiet period or during normal operation.

To request the SSs to measure one channel, the BS shall include in the DL-MAP a Channel Measurement IE as specified in 8.3.6.2.3. The BS that requests the SSs to perform a measurement shall not transmit MAC PDUs to any SS during the measurement interval. If the channel measured is the operational channel, the BS shall not schedule any UL transmissions from SSs to take place during the measurement period.

Upon receiving a DL-MAP with the Channel Measurement IE, an SS shall start to measure the indicated channel no later than **Max. Channel Switch Time** after the start of the measurement period. An SS may stop the measurement no sooner than **Max. Channel Switch Time** before the expected start of the next frame or the next scheduled UL transmission (of any SS). If the channel to be measured is the operating
channel, **Max. Channel Switch Time** shall be equal to the value of RTG, as specified in Table 575, or, in the case of **DFS Max. Channel Switch Time**, may be defined in regulation.

### 6.3.15.6 Requesting and reporting of measurements

The SS shall, for each measured channel, keep track of the following information:

- Frame Number of the frame during which the first measurement was made
- Accumulated time measured
- Existence of a specific spectrum user on the channel
- Whether a WirelessHUMAN using the same PHY system was detected on the measured channel
- Whether unknown transmissions [such as radio local area network (RLAN) transmissions] were detected on the channel

The BS may request a measurement report by sending a REP-REQ message. This is typically done after the aggregated measurement time for one or more channels exceeds the regulatory required measurement time. Upon receiving a REP-REQ the SS shall reply with a REP-RSP message and reset its measurement counters for each channel on which it reported.

If the SS detects a specific spectrum user on the channel where it is operating during a measurement interval or during normal operation, it shall immediately cease to send any user data if so mandated by regulatory requirements and send at the earliest possible opportunity an unsolicited REP-RSP. The BS shall provide transmission opportunities for sending an unsolicited REP-RSP frequently enough to meet regulatory requirements, where applicable. The SS may also send, in an unsolicited fashion, a REP-RSP when other user interference is detected above a threshold value.

### 6.3.15.7 Selecting and advertising a new channel

A BS may decide to stop operating in a channel at any time. The algorithm used to decide to stop operating in a channel is outside the scope of this standard, but shall satisfy any regulatory requirements.

A BS may use a variety of information, including information learned during SS initialization and information gathered from measurements undertaken by the BS and the SSs, to assist in the selection of the new channel. The algorithm to choose a new channel is not standardized but, in the case of DFS, shall satisfy any regulatory requirements, including uniform spreading rules and channel testing rules. If a BS would like to move to a new channel, a channel supported by all SSs in the sector should be selected.

A BS shall inform its associated SSs of the new channel using the Channel Nr in the DCD message. The new channel shall be used starting from the frame with the number given by the Channel Switch Frame Number in the DCD message. The BS shall not schedule any transmissions during the last **Max. Channel Switch Time** before the channel change is to take place.

The Uplink Burst Profiles used on the old channel defined shall be considered valid also for the new channel, i.e., the BS need not define new Uplink Burst Profiles when changing channels. When operating in license-exempt bands, the BS shall not send the Frequency (Type = 3) parameter as a part of UCD message.

### 6.3.16 MAC support for HARQ

The HARQ scheme is an optional part of the MAC. HARQ may be supported only for the OFDMA PHY. The HARQ and associated parameters shall be specified and negotiated using SBC-REQ/RSP messages during the network entry or reentry procedure. The utilization of HARQ is on a per-connection basis; in other words, it can be enabled on a per-CID basis by using the DSA message for transport connections and SBC message for management connections. Two implementations of HARQ are supported: per-terminal (i.e., enabled for all active CIDs for a terminal) and per-connection (i.e., enabled on a per-CID basis by using
the DSA/DSC messages). The two implementation methods shall not be employed simultaneously on any terminal. If HARQ is supported, SS shall support per-terminal implementation. If HARQ is supported, MS shall support per-connection implementation. A burst cannot have a mixture of HARQ and non-HARQ traffic.

One or more MAC PDUs can be concatenated and an HARQ packet formed by adding a CRC to the PHY burst. Figure 141 shows how the HARQ encoder packet is constructed.

![Figure 141—Construction of HARQ encoder packet](image)

The rule of subpacket transmission is as follows:

1) At the first transmission, BS shall send the subpacket labeled '00'.
2) BS may send one among subpackets labeled '00', '01', '10', or '11' in any order.
3) BS can send more than one copy of any subpacket, and can omit any subpacket except the subpacket labeled '00'.

In order to specify the start of a new transmission, one-bit HARQ ID sequence number (AI_SN) is toggled on every successful transmission of an encoder packet on the same HARQ channel. If the AI_SN changes, the receiver treats the corresponding subpacket as a subpacket belongs to a new encoder packet, and discards ever-received subpackets with the same ARQ ID.

The HARQ scheme is a stop-and-wait protocol. The ACK is sent by the SS after a fixed delay (synchronous ACK) defined by HARQ DL ACK delay for DL burst, which is specified in UCD message. Timing of retransmission, however, is flexible and corresponds to the asynchronous part of the HARQ. The ACK/NAK is sent implicitly by toggling the AI_SN bit or together with the HARQ ACK IE by the BS. The ACK/NAK is sent by an SS using the UL ACK subchannel. Transmission of HARQ Bitmap IE by BS is optional.

When the HARQ ACK IE is used, the bitmap contents indicate whether corresponding HARQ bursts have been received correctly. The MS shall retransmit the HARQ burst if the AI_SN bit is not toggled, and the MS shall transmit a new HARQ burst if the AI_SN bit is toggled.

The HARQ scheme supports multiple HARQ channels per connection, each of which may have an encoder packet transaction pending. The number of HARQ channels in use per connection is determined through DSA-REQ/DSA-RSP handshake or REG-REQ/REG-RSP handshake. The total number of HARQ channels in use per terminal is determined through capability negotiation using SBC-REQ/SBC-RSP handshake. These ARQ channels are distinguished by an HARQ channel identifier (ACID). The ACID for any subpackets can be uniquely identified by the control information carried in the MAPs.

HARQ can be used to mitigate the effect of channel and interference fluctuation. HARQ renders performance improvement due to SNR gain and time diversity achieved by combining previously erroneously decoded packet and retransmitted packet.
HARQ is enabled on a CID basis.

To deal with ordering implication of HARQ, each connection may enable ARQ or PDU SN mechanisms on top of the enabled HARQ connection.

Time stamp of first HARQ burst transmission is used as the time relevance for all MAC-specific management messages and subheaders (e.g., BRs, fast feedback, ARQ feedbacks) that have been transmitted in this burst.

If a Power Saving Class containing an HARQ enabled connection is active or if there is an ongoing periodic scanning procedure, then upon traffic, the BS or MS may request the deactivation of the PSC or the scanning procedure, or continue with the operation of the PSC or scanning and transmit data and ACK/NACK feedback during availability intervals (in case MS is in sleep mode) or during interleaving intervals (in case MS is performing periodic scanning). The BS shall not expect the MS to transmit ACK/NACK feedback during unavailability intervals or scan intervals even in case such allocations are scheduled.

6.3.16.1 Subpacket generation

HARQ operates at the FEC block level. The FEC encoder is responsible for generating the HARQ subpackets, as defined in the relevant PHY section. The subpackets are combined by the receiver FEC decoder as part of the decoding process.

Two main variants of HARQ are supported: chase combining and incremental redundancy (IR). SS may support IR. MS may support either chase combining or IR. For IR, the PHY will encode the HARQ packet generating several versions of encoded subpackets. Each subpacket shall be uniquely identified using a subpacket identifier (SPI). For chase combining, the PHY shall encode the HARQ packet generating only one version of the encoded packet. As a result, no SPI is required for chase combining.

For DL HARQ operation, the BS will send a version of the encoded HARQ packet. The SS will attempt to decode the encoded packet on this first HARQ attempt. If the decoding succeeds, the SS will send an ACK to the BS. If the decoding fails, the SS will send a NAK to the BS. In response, the BS will send another HARQ attempt. The BS may continue to send HARQ attempts until the SS successfully decodes the packet and sends an acknowledgement.

For IR, each HARQ attempt may have a uniquely encoded subpacket and may have different burst profile. The rule of subpacket transmission is as follows:

a) At the first transmission, the transmitting side shall send the subpacket labeled 0b00.
b) The transmitting side may send one among subpackets labeled 0b00, 0b01, 0b10, or 0b11 in any order.
c) The transmitting side can send more than one copy of any subpacket and can omit any subpacket except the subpacket labeled 0b00.

In order to specify the start of a new transmission, one-bit HARQ identifier sequence number (AI_SN) is toggled on every HARQ retransmission attempt on the same HARQ channel. If the AI_SN changes, the receiver treats the corresponding HARQ attempt as belonging to a new encoder packet and discards previous HARQ attempt with the same ARQ ID.

The HARQ scheme is basically a stop-and-wait protocol where the retransmissions are sent only after receiving a NACK signal for the previous transmission or the ACK has not been received within the duration defined by HARQ ACK Delay for UL burst (i.e., HARQ data sent by SS) or by HARQ ACK delay for DL burst (i.e., HARQ data sent by BS). As acknowledgement of DL HARQ burst sent by the BS, the ACK is sent by the SS after a fixed delay (synchronous ACK) defined by HARQ_ACK_Delay for DL Burst, which is specified in the UCD message (see Table 571). As acknowledgement of UL HARQ burst sent by
the SS, the ACK is sent by the BS after a fixed delay (synchronous ACK) defined by HARQ ACK delay for UL Burst, which is specified in the DCD message (see Table 575). Timing of retransmission is, however, flexible and corresponds to the asynchronous part of the HARQ. The ACK/NAK is sent by the BS using the HARQ Bitmap IE, and sent by an SS using the fast feedback UL subchannel.

### 6.3.16.2 DL/UL ACK/NAK signaling

For DL HARQ, fast ACK/NAK signaling is necessary. For the fast ACK/NAK signaling of DL HARQ channel, a dedicated PHY ACK/NAK channel is designed in UL. For the fast ACK/NAK signaling of UL fast feedback, HARQ ACK message is designed. The HARQ ACK/NAK message for UL HARQ may be omitted.

### 6.3.16.3 HARQ parameter signaling

The parameters for each subpacket should be signaled independent of the subpacket burst itself. The parameters for each subpacket include

- **SPID**: The BS shall set this field to the subpacket identifier for the subpacket transmission.
- **ACID**: The BS shall set this field to the ARQ channel identifier for the subpacket transmission.
- **AI_SN**: This toggles between “0” and “1” on successfully transmitting each encoder packet with the same ARQ channel.

For the signaling of those parameters, HARQ Control IE is defined, and the IE is to be placed in a Compact MAP IE, which allocates a data burst.

### 6.3.17 DL CINR report operation

This subclause applies to OFDMA mode only. The SS transmits either a physical CINR metric or an effective CINR metric using the REP-RSP MAC message or fast-feedback (CQICH) channel.

The physical CINR is defined in 8.4.12.3. The effective CINR is a function of physical CINR, varying channel conditions and implementation margin. The exact measurement method used to derive the effective CINR is implementation-specific. The reported effective CINR feedback shall correspond to the MCS in Table 520 with which the expected block error rate, assuming a specific block length, is closest to, but does not exceed, a specific target average error rate. The target average error rate and assumed block length are defined in profiles. When HARQ is employed, the computed block error rate shall only pertain to the first HARQ transmission.

The metric can be reported for one of the preamble, midamble, or a permutation zone. The manner in which the metric is derived for a permutation zone is in general implementation specific; however, the BS may explicitly instruct the SS to report the metric based on measurements from data or pilots.

The SS shall implement at least one measurement scheme and negotiate its capability.

### 6.3.17.1 DL CINR report with REP-RSP MAC message

The REP-RSP message shall be sent by the SS in response to a REP-REQ message from the BS to report estimation of DL physical CINR or effective CINR.

REP-REQ shall indicate whether the reported metric shall apply to the preamble or to a specific permutation zone. For the report on the preamble, BS can request SS to report the CINR based on the measurement from the preamble for the different frequency reuse factors or band AMC configuration. For report on a specific permutation zone, the REP-REQ indicates the report type configuration, which includes the zone for which the CINR is to be estimated. The zone is identified by its permutation type (PUSC with Use All SC = 0,
PUSC with Use All SC = 1, FUSC, Optional FUSC, AMC zone, Safety channel), and PRBS ID. Also, the same permutation and PRBS ID can be differentiated by the STC or AAS indication. Therefore, to avoid ambiguity in zone identification, the BS should never allocate in a given frame two different zones with the same permutation type, same PRBS ID and same STC or AAS indication. The SS shall not perform a measurement in a frame in which the specified zone is not allocated, and shall retain the previous measurement. For PUSC permutation zones, the SS may be instructed to report CINR estimate for only a subset of the major groups. The SS may send a REP-RSP message in an unsolicited fashion.

In the case where the requested report configuration does not differ from the previous REP-REQ message in which CINR report was requested, the SS should send its response within three frames. Otherwise, MS should respond within the period defined by Max Report Processing Time. The BS should provide the SS with a bandwidth allocation for transmission of the response. A REP-REQ message shall not contain more than one TLV requesting any type of CINR report.

For the Band-AMC differential CINR reports, the effective CINR metric shall not be used.

If the BS instructs CINR reporting on an AAS zone or zone with dedicated pilots, then the SS shall report the estimate of the physical or effective CINR measured from dedicated AAS preamble/pilot or data subcarriers that belong to slots allocated to it. For DL-PUSC in AAS mode or zone with dedicated pilots, if major-group indication has been specified in the measurement configuration then the reported CINR shall be measured on all indicated major groups rather than on slots allocated to the SS.

When calculating CINR from the midamble in an STC zone with dedicated pilots, the MS shall determine the best number of streams and precoder matrix (the choice is implementation specific), and calculate the Physical CINR if rank-1 and Avg_CINR if rank-2 according to 8.4.11.1, under assumption that the BS applies the chosen precoder and number of streams.

6.3.17.2 Periodic CINR report with fast-feedback (CQICH) channel

After an SS turns on its power, the subchannels that can be allocated to the SS are all subchannels the SS can support except the band AMC subchannel. As soon as the BS and the SS know the capabilities of both entities modulation and coding, the BS may allocate a CQICH subchannel using a CQICH IE (CQICH Allocation IE, CQICH_Enhanced_Alloc_IE, or CQICH Control IE) for periodic CINR reports (physical CINR or effective CINR).

CQICH Allocation IE may indicate whether the reported metric shall apply to preamble or to a specific permutation zone. For the report on the preamble, BS can request SS to report the CINR based on the measurement from the preamble for the different frequency reuse factors. For the report on the specific permutation zones, the CQICH Allocation IE indicates the report type configuration, which includes the zone for which the CINR is to be estimated. The zone is identified by its permutation type (PUSC with Use All SC = 0, PUSC with Use All SC = 1, AMC AAS zone, FUSC, Optional FUSC, Safety channel), and PRBS ID. Also, the same permutation and PRBS ID can be differentiated by the STC or AAS indication. Therefore, to avoid ambiguity in zone identification, the BS should never allocate in a given frame two different zones with the same permutation type, same PRBS ID and same STC or AAS indication. The SS shall not perform a measurement in a frame in which the specified zone is not allocated, and shall retain the previous measurement. For PUSC permutation zones, the SS may be instructed to report an estimate for only a subset of the major groups. The first CQICH Allocation IE sent to the SS shall indicate the report type configuration. Only a subsequent CQICH Allocation IE may update the report type configuration for CQI channel based reports. See 8.4.5.4.11 and 8.4.12.3. CQICH allocated through CQICH Control IE shall use the measurement configuration defined in the latest CQICH Allocation IE. The quantization and encoding of physical CINR and effective CINR onto the fast-feedback channel is defined in 8.4.11.

Channel Quality Information reported by a MS in Frame n pertains to measurements collected in previous frames up to and including Frame n–1, but excluding Frame n. The first CQICH report following the
CQICH allocation IE may contain invalid CQI data if the CQICH report is sent in the frame immediately following the frame in which the CQICH allocation IE was received.

A effective CINR reported on the CQI is interpreted as the SS’s recommendation that best meets the specified target error rate for the duration remaining until the next scheduled CQI report.

The SS may send an unsolicited REP-RSP message if it decides that the last effective CINR report is no longer appropriate for the duration remaining until the next periodic CQI transmission. The message is used to specify the new effective CINR for the CQI channel. The CQI channel is identified by its CQICH_ID or by the SS’s CID if the CQI channel is allocated without a CQICH_ID.

An SS may support two concurrent CQI channels (not necessarily being scheduled in the same frame)—one for effective CINR reports and one for physical CINR reports—both of which refer to the same zone. In such a case, both reported values shall be derived from the same underlying set of measurements. The CQI channel is identified by the CQICH_ID field in the CQICH Allocation IE. Support for more than one concurrent CQI channel is optional and negotiated in 11.8.3.5.8.

For the BandAMC differential CINR reports, the effective CINR scheme shall not be used.

If the BS instructs CINR reporting on an AAS zone or zone with dedicated pilots, then the SS shall report the estimate of the physical or effective CINR measured from dedicated AAS preamble/pilot or data subcarriers that belong to slots allocated to it. For DL-PUSC in AAS mode or zone with dedicated pilots, if major-group indication has been specified in the measurement configuration, then the reported CINR shall be measured on all indicated major groups rather than on slots allocated to the SS.

At any time, the BS may deallocate the SS’s CQICH by putting another CQICH IE with Duration d = 0000. Before the CQICH life timer (which is set at the receipt of the CQICH IE) expires, sending another CQICH IE overwrites all the information related to the CQICH such as Allocation Index, Period, Frame offset, and Duration. Hence, unless the BS refreshes the timer, the SS should stop reporting as soon as the timer expires. However, in case of sending the MAP IE for reallocation or deallocation, the BS should make sure if the previous CQICH is released before it is reallocated to another SS.

The SS sends the REP-RSP message in an unsolicited fashion to BS to trigger band AMC operation. The triggering conditions are given by TLV encodings in UCD messages. For SS, the REP-RSP (see 11.12 for the TLV encodings) includes the CINR measurements of four best bands. For MS, the REP-RSP (see 11.12 for the TLV encodings) includes the CINR measurements of four or five selected best bands (see 8.4.6.3.2). Only when an SS reports to its BS the CINR measurements of band AMC channels, its logical definition is made differently, as follows. If the number of physical bands is 48 (2048-FFT in 20 MHz) and the number of maximum logical bands is 12, then, the four contiguous bands are paired and renumbered the same as a 12 logical band system. If the number of physical bands is 24, the two contiguous bands are just paired and renumbered the same as a 12 logical band system. If the original number of physical bands is equal to or less than 12, the logical definition is not necessary.

The BS acknowledges the trigger from SS by sending a unicast MAC PDU to the SS using band AMC subchannels. From the next frame when the BS sends the REP-RSP, the SS starts reporting the differential of CINR from preamble or midamble for four or five selected bands (increment: 1 and decrement: 0 with a step of 1 dB) on its CQICH. The CQICH shall then be used for differential Band-AMC reports, regardless of the report configuration specified in the CQICH IE that allocated the current CQI channel. If the BS does not send a unicast MAC PDU to the SS using band AMC subchannels or send REP-REQ to indicate reporting band AMC CINR within the specified delay (CQICH band AMC transition delay) in the UCD message, the SS shall resume to report CINR according to the report configuration specified in the latest CQICH Allocation IE. In addition, if the BS sends a unicast MAC PDU to the SS using nonband AMC subchannels, or the CQICH Allocation IE indicates to report CINR on a zone other than the band AMC zone, the SS shall resume to report CINR according to the report configuration specified in the latest CQICH Allocation IE.
When the BS wants to trigger the transition to band AMC mode or update the CINR reports, it sends the REP-REQ message (see 11.11 for the TLV encodings). When the SS receives the message, it replies with REP-RSP. After BS receives the REP-RSP, the same procedure shall be used as in the triggering by the SS.

The transition of the CQICH reporting scheme from band AMC to nonband AMC mode can be made by SS and BS. At any time, SS can send REP-RSP of reporting CINR of the nonband AMC mode to trigger a transition of the CQICH reporting scheme to the nonband AMC mode. When BS receives the REP-RSP, BS may send CQICH Allocation IE to the SS to direct the nonband AMC reporting scheme. When BS does not send the CQICH Allocation IE and/or SS does not receive the CQICH Allocation IE, SS shall keep reporting the differential CINR through CQICH. At any time, BS can send CQICH Allocation IE to trigger a transition of the CQICH reporting scheme to the nonband AMC mode.

The BS may extend the duration of an existing CQICH allocation while remaining in the Band AMC differential CINR reporting mode by sending a CQICH Allocation IE to the MS and setting the “Report Configuration Included” flag to zero. This CQICH allocation IE shall contain the CQICH ID of the CQI channel being used to report Band AMC differential CINR.

6.3.17.2.1 Conditions of transition triggering

a) Normal subchannel -> AMC transition
   If the maximum of the standard deviations of the individual band’s CINR measurements from preamble is lower than the band AMC allocation threshold and the average CINR of the whole bandwidth is larger than the band AMC entry average CINR for at least Band AMC Allocation Timer frames, SS using normal subchannels sends an unsolicited REP_RSP to request mode transition. REP_RSP message contains band bitmap indicating the best four bands and their CINR measurements. The standard deviation of the individual band’s CINR measurement shall be measured over time.

b) AMC -> Normal subchannel transition
   If the maximum of the standard deviations of the individual band’s CINR measurements from preamble for at least Band AMC Release Timer frames is higher than the band AMC release threshold, SS in band AMC mode may trigger mode transition from band AMC to normal subchannel. The standard deviation of the individual band’s CINR measurement shall be measured over time.

c) Band change
   If the CINR of any one band measured from preamble or midamble excluding the best four bands previously selected for band AMC allocations is greater than the average CINR of the AMC reporting bands for at least Band AMC Allocation Timer, SS sends an unsolicited REP_RSP that contains band bitmap indicating the best four bands and their CINR measurements.

6.3.18 Optional band AMC operations using 6-bit CQICH encoding

6.3.18.1 Call flows for mode transitions between normal subchannel and band AMC

Three allocated CQICH codewords are allocated for indicating the transitions. Let the first codeword be C1 (the 62nd codeword in Table 524: 0b111101), the second one C2 (the 63rd codeword: 0b111110), and the third one C3 (the 64th codeword: 0b111111).

a) Normal -> Band AMC
   There are two possibilities for band AMC transition.

   1) MS initiated: The MS transmits C1, and the BS that receives the codeword transmits REP-REQ that includes a Type 1.3 TLV with value 0b01 (Band AMC channel). The MS replies with REP-RSP that includes a Type 2.4 TLV (Enhanced Band AMC Report TLV) having the CINR
measurements of the five best bands in the same frame as C2 or after transmitting C2. From the next frame after transmitting REP-RSP, the MS reports the Band AMC differential CQI of the selected bands. The BS may deny the MS request for mode transition as specified in 6.3.17.2.

2) BS initiated: The BS may send an unsolicited REP-REQ that includes a type 1.3 TLV with value 0b01 (Band AMC channel) to switch the allocation mode from normal subchannel to band AMC subchannel. The MS replies with REP-RSP that includes TLV type 2.4 (Enhanced Band AMC Report) having the CINR measurements of the five best bands in the same frame as C2 or after transmitting C2. The MS reports the Band AMC differential CQI of the selected bands in the frame following the REP-RSP transmission.

b) Band AMC -> Normal

The MS transmits C3. The MS reports the regular CQI of the whole bandwidth. Until the BS allocates normal subchannels, the MS repeats this process. In other words, the MS transmits the C3 and the regular CQI alternately until the normal subchannel is allocated to it.

c) Band change

The MS and its BS follows the same procedure of the transition from normal subchannel to band AMC.

d) Refreshing the CINR of the five best bands without band changes

The MS transmits an unsolicited REP-RSP at the same frame or after transmitting C2.

6.3.18.2 Conditions of transition triggering

a) Normal subchannel -> AMC transition

If the maximum of the standard deviations of the individual band’s CINR measurements is lower than the band AMC allocation threshold and the average CINR of the whole bandwidth is larger than the band AMC entry average CINR for at least Band AMC Allocation Timer frames, MS using normal subchannels sends an unsolicited to request mode transition and transmits a special codeword on its CQICH to inform its BS of its request of mode transition. REP-RSP message contains band bitmap indicating the best five bands and their CINR measurements.

b) AMC -> Normal subchannel transition

If the maximum of the standard deviations of the individual band’s CINR measurements for at least Band AMC Release Timer frames is higher than the band AMC release threshold, MS in band AMC mode may trigger mode transition from band AMC to normal subchannel.

c) Band Change

If the CINR of any one band excluding the best five bands previously selected for band AMC allocations is greater than the average CINR of the AMC reporting bands for at least Band AMC Allocation Timer, the AMC allocation bands should be changed by following the procedure given above.

6.3.19 Data delivery services for mobile network

Data delivery service is associated with certain predefined set of QoS-related service flow parameters. Note that definition of Data Delivery Service does not include assignment of specific values to the parameters.
6.3.19.1 Types of data delivery services

Type of Data Delivery Service identifies specific set of QoS parameters for the associated DL service flow (see Table 196).

Table 196—Type of data delivery services

Detailed definitions for the data delivery services of different types are given in 6.3.19.1.1 through 6.3.19.1.5.

6.3.19.1.1 Unsolicited grant service (UGS)

UGS is to support real-time applications generating fixed-rate data. This data can be provided as either fixed- or variable-length PDUs. The parameters of the service are specified in Table 197.

Table 197—UGS parameters

6.3.19.1.2 Real-time variable-rate (RT-VR) service

This service is to support real-time data applications with variable bit rates, which require guaranteed data rate and delay. The parameters of the service are specified in Table 198.

Table 198—RT-VR service parameters

<table>
<thead>
<tr>
<th>Parameter</th>

</table>

6.3.19.1.2.1 Description of the service

Let $S$ denote the amount of data arrived to the transmitter’s MAC SAP, during time interval $T =$ Time Base; and let $R =$ Minimum Reserved Traffic Rate. Then the BS is supposed, during each time interval of the length (Time Base), to allocate to the connection resources sufficient for transferring an amount of data according to the value of Minimum Reserved Traffic Rate (11.13.8) i.e., at least $\min\{S, R \times T\}$. Any SDU should be delivered within a time interval $D =$ Maximum Latency. In the case when the amount of data submitted to the transmitter’s MAC SAP exceeds $(\text{Minimum Reserved Traffic Rate}) \times T$, delivery of each specific SDU is not guaranteed.

6.3.19.1.3 Non-real-time variable-rate (NRT-VR) service

This QoS profile shall support applications that require a guaranteed data rate but are insensitive to delays. It is desirable in certain cases to limit the data rate of these services to some maximum rate. The QoS profile is defined by the parameters defined in Table 199.

Table 199—NRT-VR service parameters

<table>
<thead>

6.3.19.1.3.1 Description of the service

Let $S$ denote the amount of data arrived to the transmitter’s MAC SAP, during time interval $T = \text{Time Base}$; $R = \text{Minimum Reserved Traffic Rate}$. Then the BS is supposed during each time interval of the length (Time Base) to allocate to the connection resources sufficient for transferring amount of data according to the value of Minimum Reserved Traffic Rate (11.13.8) i.e., at least min $\{S, R \times T\}$. In the case when the amount of data submitted to the transmitter’s MAC SAP exceeds (Maximum Sustained Traffic Rate) $\times T$, delivery of each specific SDU is not guaranteed.

6.3.19.1.4 Best effort (BE) service

BE service is for applications with no rate or delay requirements. The parameters of the service are shown in Table 200.

<table>
<thead>

6.3.20 Sleep mode for mobility-supporting MS

6.3.20.1 Introduction

Sleep mode is a state in which an MS conducts prenegotiated periods of absence from the serving BS air interface. These periods are characterized by the unavailability of the MS, as observed from the serving BS, to DL or UL traffic. Sleep mode is intended to minimize MS power usage and decrease usage of serving BS air interface resources. Sleep mode may also be used to support co-located coexistence. Implementation of sleep mode is optional for the MS and mandatory for the BS.

For each involved MS, the BS keeps one or several contexts, each one related to certain Power Saving Class. Power Saving Class is a group of connections that have common demand properties. For example, all BE and NRT-VR connections may be marked as belonging to a single class while two UGS connections may belong to two different classes in case they have different intervals between consequent allocations. A connection may belong to one or several Power Saving Classes. When BS or MS activates a new PSC, which contains CID already existing in another active PSC, it shall immediately deactivate the PSC that is currently active.

It is not allowed to activate a new PSC, by unsolicited manner, which contains CID already existing in another active PSC.

In case MS or BS defines a new PSC definition using a Power_Saving_Class_ID that is already in use, the new definition replaces the existing definition with the same Power_Saving_Class_ID provided that the affected power saving class has already been deactivated.

If MS and BS have indicated support of only one active PSC in the Power saving class capability TLV, the currently active PSC shall be deactivated immediately upon activation of another PSC.

Power Saving class may be repeatedly activated and deactivated. Activation of certain Power Saving Class means starting sleep/listening windows sequence associated with this class. Algorithm of choosing Power Saving Class type for certain connections is outside of the scope of the standard. When a PSC I or PSC II is reactivated, the MS shall reset the sleep window size to the initial-sleep window size according to the definition of the PSC.

There are three types of power saving classes, which differ by their parameter sets, procedures of activation/deactivation, and policies of MS availability for data transmission.

Unavailability interval in DL or UL is a time interval that does not overlap with any listening window of any active power saving class defined in the corresponding direction.

Availability interval in UL or DL is a time interval that does not overlap with any unavailability interval in the corresponding direction.

During the unavailability interval in DL (or UL), the BS shall not transmit to the MS; therefore, the MS may power down one or more physical operation components or perform other activities that do not require communication with the BS (e.g., scanning neighbor BSs, associating with neighbor BSs). If there is a connection at the MS, which is not associated with any active power saving class, the MS shall be considered available on permanent basis.

During Availability interval in the DL (or UL), the MS is expected to receive all DL transmissions (or transmit in the UL allocations) in the same way as in the state of normal operations (no sleep). In addition, the MS shall examine the DCD and UCD change counts and the frame number of the DL-MAP PHY Synchronization field to verify synchronization with the BS. Upon detecting a changed DCD Count in DL MAP and/or UCD Count in UL MAP, unless using the Broadcast Control Pointer IE for tracking and
updating DCD and/or UCD changes, the MS shall continue reception until receiving the corresponding updated message.

If the BS transmits the Broadcast Control Pointer IE, the MS shall read and react to this message according to the following:

— If the DCD Count in DL MAP and/or UCD Count in UL MAP is different from Configuration Change Count of which DCD and/or UCD MS retains, even if scheduled to be in a sleep interval the MS shall awaken at DCD_UCD Transmission Frame in time to synchronize to the DL and decode the DCD and/or UCD message in the frame, if present. If the MS fails to decode one or both of DCD and UCD, or no DCD or UCD was transmitted by the BS, the MS shall continue decoding all subsequent frames until it has acquired updated DCD or updated UCD or both according to the change status of DCD Count and UCD Count. Upon successful completion of DCD or UCD or both DCD and UCD decoding according to the change status of DCD Count and UCD Count, the MS shall immediately return to regular sleep mode operation.

— If Skip Broadcast_System_Update is set to 0, even if scheduled to be in a sleep interval, the MS shall awaken at Broadcast_System_Update_Transmission_Frame in time to synchronize to the DL and decode and read the DL-MAP and any message, if present. Upon completion, the MS shall immediately return to regular sleep mode operation.

MS in sleep mode may request BS to allocate a scan duration by sending MOB_SCN-REQ in case trigger action for sending MOB_SCN-REQ message is enabled by Enabled-Action-Triggered TLV. When the PSC associated with the Basic CID has Traffic_triggered_wakening_flag set to 0, the MS’s PSC associated with the Basic CID shall be regarded as deactivated from the start frame of the scanning procedure specified by the BS’s MOB_SCN-RSP. However, if the MOB_SCN-RSP scan duration field indicates the denial of scanning interval allocation, the PSC shall remain activated.

The PSC associated with the Basic CID shall not be activated during scanning.

The MS may include the Sleep Mode Reactivation Information TLV (see 11.20.2) in its MOB_SCN-REQ to request automatic reactivation of the PSC associated with its Basic CID that has Traffic_triggered_wakening_flag set to 0. The BS may then include the Sleep Mode Reactivation Information TLV in its MOB_SCN-RSP to confirm the automatic reactivation and specify the frame offset from the end of the scanning procedure (i.e., end of the last scanning interval) to the start of the reactivated sleep mode operation. If the BS wants to deny the MS request for automatic PSC reactivation, the BS shall not include the Sleep Mode Reactivation Information TLV in the MOB_SCN-RSP. When this PSC is reactivated, the sleep window shall be initialized by the original PSC definition. If the MS terminates the scanning procedure abnormally, it shall consider the PSC associated with its Basic CID as deactivated.

During Unavailability intervals for MS, the BS may buffer (or it may drop) MAC SDUs addressed to unicast connections bound to an MS. The BS may choose to delay transmission of SDUs addressed to multicast connections until the following availability interval, common for all MSs participating in the multicast connection.

The MS may initiate sleep mode by transmitting MOB_SLP-REQ message, which defines the requested sleep profile. The BS may comply with the start frame as recommended by the MS and set “start frame” in MOB_SLP-RSP message as recommended by MS (first frame of unavailable interval). The BS may set start frame to the first frame of the second unavailable interval. The BS may set start frame to any other value, disregarding MS recommendation.

The MS and the serving BS shall locally deactivate all PSCs when sending or receiving a MOB_HO-IND, MOB_MSHO-REQ, or MOB_BSHO-REQ message and before handover to the target BS.
After the MS completes handover to target BS, the MS shall discard all the sleep mode related information associated with previous serving BS.

Also, a new Serving BS shall regard any MS performing handover as operating in normal operation without entering sleep mode first. The MS may include Power_Saving_Class_Parameters (see Table 583) or Unified TLV encoding for Power Saving Class Parameters (see Table 583) in the RNG-REQ message only to define Power Saving Classes. The MS may enter sleep mode after HO by activation of Power Saving Classes via MAC management message exchange. If the MS enters sleep mode, it shall transmit MOB_SLP-REQ message or Bandwidth request and uplink sleep control header to activate the previously defined Power Saving Class. Also, BS may transmit MOB_SLP-RSP or DL Sleep control extended subheader in unsolicited manner in order to activate the previously defined Power Saving Class.

In MOB_TRF-IND message with negative indication for the MS, the BS may include an updated SLPID for an MS by appending SLPID_Update TLV (11.1.7.2) in the MOB_TRF-IND message. When the received MOB_TRF-IND message includes a SLPID_Update TLV, the MS shall decode the TLV and, if addressed, update its SLPID to the new one. The MS shall identify if the SLPID_Update TLV addresses it by searching through the SLPID_Update TLV and determining if the MS’s current SLPID matches the Old_SLPID in the SLPID_Update TLV. If they match, then the MS shall set its SLPID to the New_SLPID provided in the SLPID_Update TLV. For an example of sleep mode operation, see Annex D.

MS in sleep mode may participate in periodic ranging. The procedure includes serving BS allocation of UL transmission opportunity for periodic ranging in which the MS shall transmit RNG-REQ message. After transmittal of the RNG-REQ, the MS shall wait for the RNG-RSP message. Participation in the periodic ranging procedure does not change state of power saving classes.

MS in sleep mode may maintain triggers to perform event-based actions based on the Trigger TLV encodings for CINR, RSSI, and RTD trigger (see Table 576) received in DCD message or the Neighbor BS trigger TLV encodings for Neighbor BS CINR and Neighbor BS RSSI trigger (see Table 611). received in MOB_NBR-ADV message. For this purpose, MS may include Enabled-Action-Triggered TLV (11.1.7.1) in RNG-REQ or MOB_SLP-REQ message requesting to associate specific actions with certain triggers. In response to the RNG-REQ or MOB_SLP-REQ message, BS shall transmit RNG-RSP or MOB_SLP-RSP message including Enabled-Action-Triggered TLV provided that it allows to activate the requested type of Power Saving Class. After receiving RNG-RSP or MOB_SLP-RSP message including the Enabled-Action-Triggered TLV set to one for the specific action, MS shall perform the action indicated in the Enabled-Action-Triggered TLV following function/action specified in DCD or MOB_NBR-ADV message. If MS does not include Enabled-Action-Triggered TLV in the RNG-REQ or MOB_SLP-REQ message, BS shall not include Enabled-Action-Triggered TLV in the RNG-RSP or MOB_SLP-RSP message. If the Enabled-Action-Triggered TLV is set to zero for the specific action or the Enabled-Action-Triggered TLV is not included by the BS, MS shall not perform and BS shall not expect the event-triggered action while the MS is in sleep mode.

The serving BS may verify MS exit from sleep mode by making a UL allocation for MS at any time subsequent to supposed wakening event (for example, positive indication in MOB_TRF-IND message or deactivation indicated by the unsolicited MOB_SLP-RSP message or DL Sleep control extended subheader) by transmitting at least BR message. If there are no data to transmit, BR field of the BR PDU shall be set to 0.

When receiving the MOB_SLP-RSP or DL Sleep control extended subheader in sleep mode, the MS shall follow the latest configuration and operation instruction that the BS requested.

Figure 142 describes example of behavior of MS with two power saving classes: Class A contains several connections of BE and NRT-VR type, Class B contains a single connection of UGS type. Then for Class A the BS allocates sequence of listening window of constant size and doubling sleep window. For Class B the BS allocates sequence of listening window of constant size and sleep window of constant size. The MS is
considered unavailable (and may power down) within windows of unavailability, which are intersections of sleep windows of A and B.

- Intervals of unavailability

**Figure 142—Example of sleep mode operations with two power saving classes**

### 6.3.20.2 Power saving classes of type I

Power saving class of type I is recommended for connections of BE, NRT-VR type.

For definition and/or activation of one or several power saving classes of type I the MS shall send MOB_SLP-REQ or BR and UL sleep control header (for activation only); the BS shall respond with a MOB_SLP-RSP message or DL sleep control extended subheader. The MS may retransmit MOB_SLP-REQ message or BR and UL sleep control header if it does not receive the MOB_SLP-RSP message or DL sleep control extended subheader before the T43 timer expires.

Alternatively, Power Saving Class may be defined/activated/deactivated by TLVs (i.e., Power Saving Class Parameters TLVs) transmitted in RNG-REQ and RNG-RSP message. In case of HO, Power Saving Class Parameters TLVs in RNG-REQ/RSP are used only to define Power Saving Class. When an MS or a BS specifies PSCs by using a RNG-REQ/RSP message, it shall include either a Power_Saving_Class_Parameters (see Table 583) or a Unified TLV encoding for Power Saving Class Parameters (see Table 584) for each PSC. When the MS includes the Unified TLV encoding for Power saving Class Parameters for a PSC in the RNG-REQ message, the BS shall include only Unified TLV encoding for Power saving Class Parameters for the PSC in RNG-RSP message in response to the MS’s request. Otherwise, the BS shall include Power_Saving_Class_Parameters for the RNG-RSP message in response to the MS’s request.

The following are relevant parameters:

- Initial-sleep window
- Final-sleep window base
- Listening window
- Final-sleep window exponent
- Start frame number for first sleep window
- TRF-IND required
- Traffic triggered wakening flag
Power saving class becomes active at the frame specified as start frame number for first sleep window. Each next sleep window is twice the size of the previous one, but not greater than specified final value.

\[
\text{sleepWin} = \min(2 \cdot \text{prevSleepWin}, \text{finalSleepWinBase} \cdot 2^{\text{finalSlpWinExp}})
\]

where

- \(\text{sleepWin}\) is the sleep window
- \(\text{prevSleepWin}\) is the previous sleep window
- \(\text{finalSleepWinBase}\) is the final-sleep window base
- \(\text{finalSlpWinExp}\) is the final-sleep window exponent

Sleep windows are interleaved with listening windows of fixed duration. The BS terminates the active state of the power saving class by sending MOB_TRF-IND message that includes a positive indication for the SLPID assigned to the power saving class. A traffic indication (MOB_TRF-IND) message shall be sent by the BS on Broadcast CID or Sleep Mode Multicast CID during listening window to alert MS of appearance of DL traffic demand at the corresponding connections.

When an MS receives an UL allocation after receiving a positive MOB_TRF-IND message indication or deactivation indicated by the unsolicited MOB_SLP-RSP message or DL Sleep control extended subheader, the MS shall transmit at least BR message. If there is no data to transmit, BR field of the BR PDU shall be set to 0.

Power saving class is deactivated either by MOB_SLP-REQ/BR and UL sleep control header or MOB_SLP-RSP/DL sleep control extended subheader messages.

The PSC shall be deactivated if traffic triggering wakening flag is set to 1 and if any of the following conditions is met:

- MS receives a MAC PDU over any connection belonging to the Power Saving Class
- MS transmits a bandwidth request with BR set to a value other than 0 on any connection belonging to the Power Saving Class

If the TRF-IND_Required flag was set in MOB_SLP-RSP, Power Saving Class shall be deactivated if MS failed to receive MOB_TRF-IND message during any Availability interval that contains at least one listening window of Power Saving Class of type I.

During Availability intervals, the MS is expected to receive all DL transmissions same way as in the state of normal operations (no sleep).

### 6.3.20.3 Power saving classes of type II

Power saving class of type II is recommended for connections of UGS, RT-VR type. The following are relevant parameters:

- Initial-sleep window
- Listening window
- Start frame number for first sleep window

Power Saving Class becomes active at the frame specified as “Start frame number for first sleep window.” All sleep windows are of the same size as initial window. Sleep windows are interleaved with listening windows of fixed duration. Power Saving Classes of this type are defined/activated/deactivated by
MOB_SLP-REQ/MOB_SLP-RSP or activated/deactivated by bandwidth request and uplink sleep control header/DL Sleep control extended subheader transaction. The MS may retransmit MOB_SLP-REQ message or Bandwidth request and uplink sleep control header if it does not receive the MOB_SLP-RSP message or DL Sleep control extended subheader within the T43 timer. The BS may send unsolicited MOB_SLP-RSP or DL Sleep control extended subheader to initiate activation of Power Saving Class. Once started, the active state continues until explicit termination by MOB_SLP-REQ/MOB_SLP-RSP messages or Bandwidth request and uplink sleep control header/DL Sleep control extended subheader. BS may send unsolicited MOB_SLP-RSP message or DL Sleep control extended subheader to deactivate Power Saving Class. Alternatively Power Saving Class of type II may be defined and/or activated/deactivated by TLVs transmitted in RNG-REQ and RNG-RSP message. In case of HO, Power Saving Class Parameters TLVs in RNG-REQ/RSP are used only to define Power Saving Class. When an MS or a BS specifies PSCs by using a RNG-REQ/RSP message, it shall include either a Power_Saving_Class_Parameters (see Table 583) or a Unified TLV encoding for Power Saving Class Parameters (see Table 584) for each PSC. When the MS includes the Unified TLV encoding for Power saving Class Parameters for a PSC in the RNG-REQ message, the BS shall include only Unified TLV encoding for Power saving Class Parameters for the PSC in the RNG-RSP message in response to the MS’s request. Otherwise, the BS shall include Power_Saving_Class_Parameters for the RNG-RSP message in response to the MS’s request.

During listening windows of power saving class type II, the MS may send or receive any MAC SDUs or their fragments at connections comprising the power saving class as well as acknowledgements to them. The MS shall not receive or transmit MAC SDUs during sleep windows.

6.3.20.4 Power saving classes of type III

Power saving class of type III is recommended for multicast connections as well as for management operations, for example, periodic ranging, DSx operations, MOB_NBR-ADV etc. Power saving classes of this type are defined/activated by MOB_SLP-REQ/MOB_SLP-RSP or BR and UL sleep control header/DL sleep control extended subheader transaction. The MS may retransmit MOB_SLP-REQ message (or BR and UL sleep control header) if it does not receive the MOB_SLP-RSP message (or DL sleep control extended subheader) within the T43 timer. The BS may send unsolicited MOB_SLP-RSP or DL sleep control extended subheader to initiate activation of power saving class. Deactivation of power saving class occurs automatically after expiration of sleep window.

Alternatively, power saving class of type III may be defined/activated by TLV encodings in RNG-RSP message. For periodic ranging Next Periodic Ranging TLV encoding may be used. It activates special power saving classes of type III associated with periodic ranging procedure (as described in 6.3.20.5.1) or keep-alive check (as described in 6.3.20.7.2). In this case the sleep window of the class starts in the next frame after RNG-RSP transmitted and ends in the previous frame, which Next Periodic Ranging TLV encoding (11.1.7.3) indicates.

If Next Periodic Ranging TLV encoding is included in MOB_SLP-RSP, this activates power saving class of type III for periodic ranging and BS can continue to activate the power saving class using Next Periodic Ranging TLV encoding in RNG-RSP message with ranging status set to success.

The following are relevant parameters except in the case that Next Periodic Ranging TLV encoding is used:

- Final-sleep window base
- Final-sleep window exponent
- Start frame number for sleep window

In case Next Periodic Ranging TLV encoding is used, MS shall regard the Start frame number for sleep window as 1 frame and calculate the next frame to wake by using Next Periodic Ranging TLV encoding.
Power saving class becomes active at the frame specified as “Start frame number for first sleep window.” Duration of sleep window is specified as base/exponent. After the expiration of the sleep window power saving class automatically becomes inactive.

For multicast service BS may guess when the next portion of data will appear. Then the BS allocates sleep window for all time when it does not expect the multicast traffic to arrive. After expiration of the sleep window multicast data, if already available, may be transmitted to relevant MSs. After that, the BS may decide to reactivate power saving class.

As an example, power saving class of type III may include Basic connection to serve needs of periodic ranging. In this case, duration (base/exponent) of sleep window shall be equal to time interval needed before next Periodic ranging transaction. Then the MS, after the specified time interval, shall be available to DL transmission and BS may either allocate an UL transmission opportunity for RNG-REQ or send unsolicited RNG-RSP. Reactivation of the power saving class may be achieved using, for example, TLVs included into RNG-REQ/RSP.

Alternatively, power saving class of type III may be activated/deactivated by TLVs transmitted in RNG-RSP messages. In case of HO, Power Saving Class Parameters TLVs in RNG-REQ/RSP are used only to define Power Saving Class. When an MS or a BS specifies PSCs by using a RNG-REQ/RSP message, it shall include either a Power_Saving_Class_Parameters TLV (see Table 583) or a Unified TLV encoding for Power Saving Class Parameters (see Table 584) for each PSC. When the MS includes the Unified TLV encoding for Power saving Class Parameters for a PSC in the RNG-REQ message, the BS shall include only Unified TLV encoding for Power saving Class Parameters for the PSC in RNG-RSP message in response to the MS’s request. Otherwise, the BS shall include a Power_Saving_Class_Parameters TLV for the in RNG-RSP message in response to the MS’s request.

### 6.3.20.5 Periodic ranging in sleep mode

In case of OFDMA PHY, MS performs CDMA code-based Periodic Ranging according to 6.3.20.5.2.

In case of other PHYs (SC and OFDM), Message-based Periodic ranging is used as described in 6.3.20.5.1.

#### 6.3.20.5.1 Periodic ranging in sleep mode for PHYs (SC and OFDM)

For each MS in sleep mode, during its listening window, BS may allocate an UL transmission opportunity for periodic ranging. Alternatively, BS may return the MS to normal operation by deactivation of at least one power saving class to keep it in active state until assignment of a UL transmission opportunity for periodic ranging, or let the MS know when the periodic ranging opportunity shall occur with Next Periodic Ranging TLV (11.1.7.3) in last successful RNG-RSP.

During periodic ranging or negotiation of sleep mode, after RNG-REQ (or MOB_SLP-REQ) reception, BS shall send RNG-RSP (or MOB_SLP-RSP, respectively) including Next Periodic Ranging TLV so that MS can know when to perform periodic ranging as described in more details in 6.3.23.1. In the frame specified by Next Periodic Ranging TLV, the MS shall decode all consequent UL-MAP messages waiting for a UL unicast transmission opportunity for periodic ranging. When such an opportunity occurs, the MS shall transmit a RNG-REQ message to the BS and then perform the regular procedure for periodic ranging. A successful periodic ranging procedure does not deactivate another Power Save Classes. In the case where periodic ranging procedure fails, the MS shall perform Initial Ranging procedure or handover to another BS.

When the periodic ranging operation between MS and BS successfully processes, the BS may inform the MS of the frame number in which the next periodic ranging operation is expected to start. For that, BS shall append a Next Periodic Ranging TLV encoding to the RNG-RSP message. BS also may inform MS of the existence of DL Traffic addressed to MS. For that, BS shall include the Next Periodic Ranging TLV with a value set to zero. This deactivates all power saving classes at the MS. If an MS receives the RNG-RSP
message with this indication from the BS, then the MS shall immediately resume normal operation with the BS.

The BS may include a SLPID_Update TLV (11.1.7.2) item in a RNG-RSP message for an MS in sleep mode. If the serving BS receives a RNG-REQ message from an MS in sleep mode and there is any need to update SLPID assigned to the MS, the BS shall append a SLPID_Update TLV to the RNG-RSP message only for a RNG-RSP message with ranging status flag set to success. When the received RNG-RSP message with ranging status flag set to Success includes a SLPID_Update TLV, the MS shall decode the TLV and update its SLPID to the new one. The MS shall identify if the SLPID_Update TLV addresses it by searching through the SLPID_Update TLV and determining if the MS’s current SLPID matches the Old_SLPID in the SLPID_Update TLV. If they match, then the MS shall set its SLPID to the New_SLPID provided in the SLPID_Update TLV.

### 6.3.20.5.2 Periodic ranging in sleep mode for OFDMA PHY

Upon expiration of MS Timer T4 shown in Figure 102, MS may perform CDMA-based periodic ranging according to method described in 6.3.10.3.2. CDMA code-based Periodic Ranging can be performed during any interval or MS may skip the periodic ranging depending on vendor implementation. MS may anonymously extend its Availability interval in order to wait the reception of RNG-RSP message with ranging status = Success or find an appropriate ranging opportunity for sending/resending of CDMA code-based ranging request. Such temporary extension of Availability interval is not known by the BS and shall not affect the previously negotiated status of the sleep mode between MS and BS.

### 6.3.20.6 MDHO/FBSS diversity set maintenance in sleep mode

An MS in sleep mode shall maintain the diversity set and anchor BS if at least one active power saving class has the Maintain Diversity Set and Anchor BSID set to 1 and the MDHO/FBSS duration as specified in the MOB_SLP-RSP message has not expired. Before the MDHO/FBSS duration expires, the MS shall continue to monitor the signal strength of neighbor BS and initiate deactivation of at least one power saving class to keep in normal mode to perform diversity set update procedure (defined in 6.3.21.3.3) or anchor BS update procedure (defined in 6.3.21.3.4).

### 6.3.20.7 Keep-alive check in sleep mode

In order for BS to maintain supervision of MSs in sleep mode and to perform necessary adjustments, BS may implement a keep-alive check mechanism. There are two methods for Keep-Alive check in sleep mode: Message-based and unsolicitedly grant of UL bandwidth during an availability interval. Those schemes are controlled by BS. If there is Next Periodic Ranging TLV encoding in MOB_SLP-RSP message during sleep mode negotiation, Keep-Alive check operation as described in 6.3.20.7.1 is used. Otherwise, Keep-Alive check operation described in 6.3.20.7.2 can be used.

### 6.3.20.7.1 OFDMA message-based keep-alive check in sleep mode

For Keep-Alive check for an MS in sleep mode, BS may include Next Periodic Ranging TLV encoding in MOB_SLP-RSP or RNG-RSP message. In this case, BS shall allocate an UL transmission opportunity for RNG-REQ message to an MS in the frame specified by Next Periodic Ranging TLV encoding. And, MS shall transmit a RNG-REQ message on the UL burst allocated by the BS. When BS receives the first RNG-REQ message on UL burst allocated by the BS, BS shall send unconditionally a RNG-RSP with ranging status = Success including Next Periodic Ranging TLV encoding so that MS can know when to perform keep-alive operation in future. But, if the BS wants to perform additional adjustment for the MS, BS may send the RNG-RSP message with ranging status = Continue including Next Periodic Ranging TLV encoding so that the MS can know when to perform keep-alive operation in future. In this case, MS shall remain awake and perform CDMA code-based Periodic Ranging operation (refer to 6.3.10.3.2) until BS sends the
RNG-RSP message with ranging status = Success. MS can enter sleep mode again till the frame indicated by the Next Periodic Ranging TLV encoding, if possible.

In the frame specified by Next Periodic Ranging TLV, when BS allocates a UL transmission opportunity to an MS, BS starts a timer T49 at the same time and wait to receive a first RNG-REQ message from the MS on the UL transmission opportunity. When BS receives the first RNG-REQ message from the MS on the UL burst, BS shall unconditionally terminate T49 timer. If BS does not receive a RNG-REQ message from MS on the UL burst for the MS, it shall continue to allocate a UL unicast burst to the MS as long as the T49 runs. But, if the T49 expires, BS shall regard the MS as being MAC-Initialized. On the other hand, in the frame specified by Next Periodic Ranging TLV, MS shall wake up and try to recognize an allocation of a UL unicast burst allocated by BS. MS shall start a timer T48 at the same time. MS shall reset T48 whenever it receives its own UL burst allocation without RNG-RSP message for the MS. And, MS shall terminate T48 when it receives a RNG-RSP message. MS shall maintain awake so as to receive a RNG-RSP message from BS as long as the T48 runs. If T48 timer expires, MS may perform Network Entry.

When the Keep-Alive check operation between MS and BS successfully processes, the BS shall inform the MS of the frame number in which the next Keep-Alive check operation is expected to start. For that, BS shall append a Next Periodic Ranging TLV encoding to the RNG-RSP message. If MS receives a RNG-RSP message with ranging status = Success including Next Periodic Ranging TLV encoding, MS shall recognize the frame to wake up for next Keep-Alive check. If MS receives a RNG-RSP message with ranging status = Continue including Next Periodic Ranging TLV encoding, MS shall perform CDMA code-based Periodic Ranging together with saving of the frame to wake up for next Keep-Alive check. BS may send RNG-RSP message with Ranging Status = Abort, In this case, BS regards the MS as being MAC-Initialized and MS shall perform Network Entry to a BS.

At the time of successful Keep-Alive check, BS may inform MS of the existence of DL Traffic addressed to MS. For that, BS shall include the Next Periodic Ranging TLV with a value set to zero. This deactivates all Power Saving Classes at the MS. If an MS receives the RNG-RSP message with this indication from the BS, then the MS shall immediately resume Normal Operation with the BS. The BS may also include a SLPID_Update TLV item in a RNG-RSP message for an MS in sleep mode. If BS receives a RNG-REQ message from an MS and there is any need to update SLPID assigned to the MS, the BS shall append a SLPID_Update TLV to the RNG-RSP message. When MS receives RNG-RSP message with a SLPID_Update TLV, the MS shall decode the TLV and update its SLPID to the new one. The MS shall identify if the SLPID_Update TLV addresses it by searching through the SLPID_Update TLV and determining if the MS’s current SLPID matches the Old_SLPID in the SLPID_Update TLV. If they match, then the MS shall set its SLPID to the New_SLPID provided in the SLPID_Update TLV.

6.3.20.7.2 OFDMA keep alive check by UL data grants in sleep mode

BS may implement keep-alive signaling by unsolicited allocating UL data grants during an Availability interval. The MS shall respond to such a data grant sending any data whereas it is clarified that an UL message with BR=0 shall not affect the status of current sleep mode according to 6.3.20.2.

BS may also during an availability interval transmit an unsolicited RNG-RSP messages with frequency, timing or power offsets, whereas MS shall use these new offsets during next time of transmitting, determined by next UL-grant. New assigned power offset shall also be used in case MS decides to wake up and perform CDMA based ranging or bandwidth request due to data in buffers.

6.3.20.8 Sleep mode supporting co-located coexistence

The MS may include the Co-located-Coexistence-Enabled TLV in the MOB_SLP-REQ to define or define and activate a PSC for co-located coexistence support. The MS may include the Co-located-Coexistence-Enabled TLV in the MOB_SLP-REQ only if PSC-based co-located coexistence mode 1 or mode 2 was negotiated during registration (see 11.7.8.9).
Only one PSC shall be active at any given time per MS when sleep mode is used to support co-located coexistence. The active PSC supporting co-located coexistence shall be defined with Traffic_triggered_wakening_flag set to 0 and the TRF-IND_Required flag set to 0.

In case a PSC supports co-located coexistence mode 1 or mode 2, the BS shall not deactivate the PSC. Furthermore, the BS is required to honor the configuration for the PSC in the MS MOB_SLP-REQ message meaning the BS does not gratuitously reject or modify the configuration for the PSC in the MS MOB_SLP-REQ as multi-radio operation in the MS will suffer due to co-located radio interference. The BS shall not provide any MS DL/UL allocation in the sleep window of the PSC supporting co-located coexistence. The MS may request deactivation of the active PSC supporting co-located coexistence or switch to a PSC without co-located coexistence support in case co-located coexistence support is no longer needed.

If the PSC supporting co-located coexistence in mode 2 (bit 1 of Co-located-Coexistence-Enabled TLV is set to 1), the BS shall not provide any MS UL allocation in the first frame of the PSC listening interval and should provide any DL allocation in the first frame of the PSC listening interval. Furthermore, the BS should populate the DL subframe the way that DL allocations for all MS with active Co-located-Coexistence-Enabled PSCs precede in time the allocations for other MS. Activation/deactivation of the PSC supporting co-located coexistence mode 2 may be triggered by the MS depending on DL channel quality estimation and/or interference from co-located and coexisting radios.

The MS may request the BS to allocate UL band AMC subchannels to reduce co-located radio interference by setting bit 3 to 1 in the Co-located-Coexistence-Enabled TLV. The BS should allocate the subchannels as much as possible to the uppermost (if bit 4 is set to 1) or lowermost side (if bit 4 is set to 0) of the available channel bandwidth in order to increase the frequency separation between the interfering radio channels of the MS.

### 6.3.20.9 MAP relevance for Sleep Mode

When the MAP relevance for sleep mode feature has been negotiated (bit 2 of Co-located-Coexistence-Enabled TLV is set to 1 and/or bit 0 in the sleep mode functions enabled in H-FDD TLV is set to 1), the BS should schedule the listening and sleep intervals for this MS following the MAP relevance based on MS’s request using MOB_SLP-REQ:

- MAP relevance bit = 1 defines that the listening and sleep intervals follow the MAP relevance (e.g., for OFDMA, when the DL-MAP is relevant to the DL subframe of current frame and the UL-MAP is relevant to the UL subframe of the following frame, the UL subframe of each listening and sleep interval is shifted to a next frame compared to the DL subframe of that interval).
- MAP relevance bit = 0 defines that the listening and sleep intervals are aligned on the same frame number for the UL and the DL subframes.

As an example, Figure 143 illustrates the co-located coexistence PSC for dual frame cycle sleep mode usage (i.e., the listening interval and sleep interval lengths are each 1 frame) starting at frame \( n + 1 \) in a TDD case (MAP relevance bit 2 of Colocated-Coexistence-Enabled TLV is set to 1 and the sleep mode functions enabled in H-FDD TLV is absent or bit 0 in this TLV is set to 0).
6.3.21 MAC HO procedures

This subclause contains the procedures performed during HO.

An MS shall be capable of performing HO using the procedures defined in 6.3.21.2.

The HO process defined in this subclause may be used in a number of situations. Some examples are as follows:

— When the MS moves and (due to signal fading, interference levels, etc.) needs to change the BS to which it is connected in order to provide a higher signal quality.
— When the MS can be serviced with higher QoS at another BS.

The HO decision algorithm is beyond the scope of the standard.

6.3.21.1 Network topology acquisition

6.3.21.1.1 Network topology advertisement

A BS shall broadcast information about the network topology using the MOB_NBR-ADV message. The message provides channel information for neighboring BSs normally provided by each BS’s own DCD/UCD message transmissions. A BS may obtain that information over the backbone network. Availability of this information facilitates MS synchronization with neighboring BS by removing the need to monitor transmission from the neighboring BS for DCD/UCD broadcasts.

The MS shall support at least $N_{MS_{max_{neighbors}}}$ total neighbors in a single or fragmented MOB_NBR-ADV message. If the MOB_NBR-ADV contains more neighbors than the MS can support, the MS shall retain neighbors that are defined first in the MOB_NBR-ADV and discard subsequent neighbors. For example, if the MS supports a maximum of $N_{MS_{max_{neighbors}}}$ neighbors but the BS sends a MOB_NBR-ADV with $N_{MS_{max_{neighbors}}} + K$ neighbors, the MS should keep the first $N_{MS_{max_{neighbors}}}$ neighbors (with index $0 \leq j < N_{MS_{max_{neighbors}}}$) and discard later neighbors (with index $j \geq N_{MS_{max_{neighbors}}}$).
When the MOB_NBR-ADV message is fragmented, the MS should not send MOB_MSHO-REQ or MOB_SCN-REP using the neighbor BS index until all prior fragments are received.

6.3.21.1.2 MS scanning of neighbor BSs

A BS may allocate time intervals to MS for the purpose of MS seeking and monitoring suitability of neighbor BSs as targets for HO. The time during which the MS scans for available BS will be referred to as a scanning interval.

An MS may request an allocation of a group of scanning intervals with interleaving intervals of normal operation and recommended start frame of first scanning interval (by including recommended start frame) using the MOB_SCN-REQ message for the purpose of reducing the number of MOB_SCN-REQ and MOB_SCN-RSP messages required to create multiple scanning opportunities when frequent scanning is required. The MS indicates in this message the estimated duration of time it requires for the scan.

The BS may comply with the recommended start frame and set “start frame” in MOB_SCN-RSP message as recommended by MS (First frame of first scanning interval). The BS may set start frame to the first frame of the second scanning interval. The BS may set start frame to any other value, disregarding MS recommendation.

Scanning interval repeats with the number of Scan iteration. An interleaving interval is interleaved between two consecutive scanning intervals.

If an MS is performing Autonomous scanning while the trigger condition is met, then the MS shall continue to perform Autonomous scan. In the MOB_SCN-REQ message the MS (the MOB_SCN-RSP message the BS) shall indicate group of neighbor BSs for which only Scanning or Scanning with Association are requested by MS (recommended by BS). Presence of those BSs for which Association is requested (recommended) is indicated by encoding of Scanning type ≥ 0b001. The BS may negotiate over the backbone with a BS Recommended for Association allocation unicast ranging opportunities. Then the MS will be informed on Rendezvous time to conduct Association ranging with the Recommended BS. When conducting initial ranging to a BS recommended for Association, MS shall use allocated unicast ranging opportunity, if available. Regardless of the presence of recommended BSIDs, MS may determine and perform any scanning or Association activities during scanning interval at its own discretion. When the report mode is 0b10 in the MOB_SCN-RSP message, the MS shall scan all BSs within the Recommended BS list of the message and then report the scanning result with the MOB_SCN-REP message as conditioned by specified trigger event. Particularly if the Trigger Function in the most recently-received DCD channel encoding is 0x5 or 0x6, the MS shall include within the MOB_SCN-REP all recommended BSs for which the MS holds a valid and updated metric measure. Otherwise, the MS shall add only the BSs that met the Trigger Function conditions within the MOB_SCN-REP message. The scanning duration performed by the MS on all neighbor BSs shall be no longer than the parameter Max_Dir_Scan_Time (as specified in 10.1) to limit the time before a report is sent to the BS.

Upon reception of the MOB_SCN-REQ message, the BS shall respond with a MOB_SCN-RSP message. The MS may retransmit the MOB_SCN-REQ message if it does not receive the MOB-SCN-RSP message within the T44 timer. The MOB_SCN-RSP message shall either grant the requesting MS a scanning interval that is at least as long as requested by that MS, or deny the request. A value of zero for Scan duration in MOB_SCN-RSP shall indicate the request for an allocation of scanning interval is denied. The serving BS may also send MOB_SCN-RSP message unsolicited. For unsolicited MOB_SCN-RSP message transmitted without assignment of scanning interval, a value of zero for Scan duration is used to trigger MS to report scanning result, without explicitly assigning scanning intervals to the MS. In this case, the MS shall only update Report Mode, Report Period and Report Metric based on the information received in MOB_SCN-RSP message.
When the Report Mode is 0b11, the MS should report its actual scanning results for neighbors that were scanned due to a previous MOB_SCN-RSP message as well as due to previous autonomous scanning.

In the event of a race condition where, after the BS sends an unsolicited MOB_SCN-RSP message, the MS sends a MOB_SCN-REQ message before it receives the BSs MOB_SCN-RSP message, the BS shall respond to the MOB_SCN-REQ message with another unsolicited MOB-SCN-RSP message (in the interleaving interval of the previous MOB_SCN-RSP message) that shall overwrite the previous one.

When multiple MOB_SCN-RSP (solicited or unsolicited) messages are received by the MS (over time) and if the MS responds to any of the messages, then the MS shall always respond to the most recent message.

Following reception of a MOB_SCN-RSP message granting the request, beginning at Start frame an MS may scan for one or more BS during the time interval allocated in the message. When a BS is identified through scanning, the MS may attempt to synchronize with its DL transmissions, and estimate the quality of the PHY channel.

The serving BS may buffer incoming data addressed to the MS during the scanning interval and transmit that data after the scanning interval during any interleaving interval or after exit of the scanning mode.

An MS may terminate scanning and return to Normal Operation anytime that may be indicated to the BS by sending a MAC PDU (for example, Bandwidth request) during any scanning interval. If a serving BS receives a MAC PDU message during any scanning interval from an MS that is supposed to be in Scanning Mode, the BS shall assume that the MS is no longer in Scanning Mode. The group of intervals is terminated at any time if the MS sends MOB_SCN-REQ message with Scan Duration set to zero or serving BS sends MOB_SCN-RSP message with Scan Duration set to zero during any interleaving interval. Upon reception of the MOB_SCN-REQ message with zero Scan Duration, the BS shall respond with a MOB_SCN-RSP message with Scan Duration set to zero and Report Mode set to 0b00 (No report). If HO negotiation is started at the time of an ongoing scanning process, the group of scanning intervals shall be terminated when the MS transmits MOB_MSHO-REQ for MS-initiated HO and when the BS transmits MOB_BSHO-REQ for BS-initiated HO. The MS may renegotiate scanning intervals with the Serving BS upon transmission of HO-IND with HO_IND_type = 0b01 or HO_IND_type = 0b10.

6.3.21.1.3 Association procedure

Association is an optional initial ranging procedure occurring during scanning interval with respect to one of the neighbor BSs. The function of Association is to enable the MS to acquire and record ranging parameters and service availability information for the purpose of proper selection of HO target and/or expediting a potential future HO to a target BS. Recorded ranging parameters of an Associated BS may be further used for setting initial ranging values in future ranging events during actual HO.

There are three levels of association as follows:

— Association Level 0: Scan / Association without coordination
— Association Level 1: Association with coordination
— Association Level 2: Network assisted association reporting

Upon completion of a successful MS initial ranging of a BS, if the RNG-RSP message contains a Service Level Prediction parameter set to 2, the MS may mark the BS as Associated in its MS local Association table of identities, recording elements of the RNG-RSP to the MS local Association table, and setting an appropriate aging timer (see Table 554). Association state in the MS local Association table shall be aged-out after ASC-AGING-TIMER timeout and the Association entry removed.

The BS may direct the MS to associate with recommended BSs by setting scanning type to 0b010 or 0b011 in MOB_SCN-RSP. If the MS supports directed association, it shall perform association as directed by the
serving BS. If MS does not support directed association, it may ignore this message. The support of directed association shall be negotiated as part of SBC-REQ and SBC-RSP MAC management message dialog.

6.3.21.1.3.1 Association level 0—Scan/Association without coordination

When this association level is chosen by the network, the serving BS and the MS negotiate about the association duration and intervals (via MOB_SCN-REQ with scanning type = 0b001 and MOB_SCN-RSP). The serving BS allocates periodic intervals where the MS may range neighboring BSs; however, the target BS has no knowledge of the MS and provides only contention-based ranging allocations. An MS chooses randomly a ranging code from the initial ranging domain of the target BS and transmits it in the contention-based ranging interval of the target BS.

After the BS successfully receives ranging code and sends RNG-RSP message with ranging status Success, it will provide UL allocation of adequate size for the MS to transmit RNG-REQ message with TLV parameters (serving BSID, MS MAC address) related to the association ranging.

6.3.21.1.3.2 Association level 1—Association with coordination

When this association level is chosen, the serving BS provides association parameters to the MS and coordinates association between the MS and neighboring BSs.

The MS may request to perform association with coordination by sending the MOB_SCN-REQ message to the serving BS with scanning type = 0b010. This message will include a list of neighboring BSs with which the MS wishes to perform association. The serving BS may also arrange for this type of association unilaterally by sending unsolicited MOB_SCN-RSP.

The serving BS will then coordinate the association procedure with the requested neighboring BSs.

Each neighboring BS will provide a ranging region for association at a predefined “rendezvous time,” in terms of relative frame number. The neighboring BS will also assign the following:

- A unique code number (from within the initial ranging codeset)
- A transmission opportunity within the allocated region (in terms of offset from the start of the region)

The neighboring BS may assign the same code or transmission opportunity to more than one MS, but not both. In case all allocated transmission opportunities in current region are different, there is no potential for collision of transmissions from different MSs. In case the serving BS allocates the same transmission opportunity to several MSs, there is some probability of collision and then neighbor BS may fail to identify transmitted codes.

The serving BS (of the associating MS), will coordinate to assure that the neighboring BSs do not assign overlapping or too close in time to each other ranging regions.

The serving BS will provide the preassigned association ranging info via the MOB_SCN-RSP message.

When the Dedicated ranging indicator is set to 1, the ranging region will be allocated via UIUC = 12 in the UL-MAP.

When “Dedicated ranging indicator” is set to 1, then the ranging region and ranging method defined could be used for the purpose of ranging using dedicated CDMA code and Tx opportunity assigned in the MOB_PAG-ADV message (for location update in idle mode) or in the MOB_SCN-RSP message (for coordinated association).
MSs registered to this BS are prohibited from use of the named ranging region.

Upon receiving the MOB_SCN-RSP message, the MS should interpret the provided “rendezvous time,” dedicated code, and transmission opportunity as follows:

— “Rendezvous time” specifies the frame in which the neighbor BS will transmit a UL-MAP containing the definition of the dedicated ranging region where the MS can use the assigned CDMA ranging code. “Rendezvous time” is provided in units of frames, beginning at the frame where the MOB_SCN-RSP message is transmitted.

— The MS shall synchronize to the neighbor BS at the first frame immediately following the rendezvous time, read the UL-MAP transmitted at this frame, and extract the description of the dedicated ranging region (ranging region with “Dedicated ranging indicator” bit set to 1). The MS shall determine the specific region it should use for transmission of the dedicated CDMA code by applying the offset defined by the Transmission Opportunity Offset field in MOB_SCN-RSP, which was received from the serving BS, to the dedicated ranging region definition in the UL-MAP of the neighbor BS. In case the neighbor BS decides to provide a regular (nondedicated) ranging region with Dedicated ranging indicator set to 0, the MS may transmit the allocated CDMA code in the regular ranging region.

— If the MS could not obtain UL_MAP at the first frame immediately following the rendezvous time, it shall abort the Level 1 association process it is attempting with the current BS. The MS may perform the Level 0 association with this BS as defined in 6.3.21.1.3.1 after it aborts the Level 1 association process.

6.3.21.1.3.3 Association level 2—Network-assisted association reporting

The MS may request to perform association with network assisted association reporting by sending the MOB_SCN-REQ message to the serving BS with scanning type = 0b011. This message will include a list of neighboring BSs with which the MS wishes to perform association. The serving BS may also request this type of association unilaterally by sending the MOB_SCN-RSP message.

The serving BS will then coordinate the association procedure with the requested neighboring BSs in a fashion similar to association Level 1. However, when using this association type, the MS is required only to transmit the CDMA ranging code at the neighbor BS. Then the MS does not have to wait for RNG-RSP from the neighbor BS. Instead, the RNG-RSP information on PHY offsets will be sent by each neighbor BS to the serving BS (over the backbone network). The serving BS may aggregate all ranging related information into a single MOB_ASC_REPORT message.

When receiving this message, the MS updates its association database (PHY offsets and CIDs) and timers for each associated BS.

If no ranging region exists with Dedicated Ranging Indicator set to 1 but a regular (nondedicated) ranging region is allocated by the BS at the rendezvous time, then MS may use this allocation for the coordination process. In this case, the MS may transmit the allocated CDMA code in the region defined via UL-MAP IE with UIUC = 12 (i.e., the regular ranging region). The MS shall also in this case ignore the value of the Transmission Opportunity Offset field of the MOB_SCN-RSP message it received from the serving BS during the association negotiation. The neighbor BS that decides to provide a regular (nondedicated) ranging region instead of a ranging region with Dedicated ranging indicator set to 1, should expect to receive the allocated CDMA code in the regular (nondedicated) ranging region. If the MS could not obtain UL_MAP at the first frame immediately following the rendezvous time, it shall abort the Level 2 association process its attempting with the current BS. The MS may perform the Level 0 association with this BS as defined in 6.3.21.1.3.1 after it aborts the Level 2 association process.
6.3.21.2 HO process

The subclause defines the HO process in which an MS migrates from the air-interface provided by one BS to the air-interface provided by another BS. The HO process consists of the following stages:

- **Cell reselection**—MS may use neighbor BS information acquired from a decoded MOB_NBR-ADV message or may make a request to schedule scanning intervals or sleep intervals to scan, and possibly range, neighbor BSs for the purpose of evaluating MS interest in HO to a potential target BS. The cell reselection process need not occur in conjunction with any specific, contemplated HO decision.

- **HO Decision and Initiation**—An HO begins with a decision for an MS to HO from a serving BS to a target BS. The decision may originate either at the MS or the serving BS. The HO Decision consummates with a notification of MS intent to HO through MOB_MSHO-REQ or MOB_BSHO-REQ message.

- **Synchronization to target BS DL**—The MS shall synchronize to the DL transmissions of the Target BS and obtain DL and UL transmission parameters. If the MS had previously received a MOB_NBR-ADV message including Target BSID, Physical Frequency, DCD and UCD, this process may be shortened. If the Target BS had previously received HO notification from the Serving BS over the backbone, then the Target BS may allocate one or more non-contention-based initial ranging opportunities.

- **Ranging**—MS and target BS shall conduct initial ranging per 6.3.9.5 or HO ranging per 6.3.10.4. If MS RNG-REQ includes serving BSID, then target BS may make a request to serving BS for information on the MS over the backbone network and serving BS may respond. Regardless of having received MS information from serving BS, target BS may request MS information from the backbone network. Network reentry proceeds per 6.3.9 except as may be shortened by target BS possession of MS information obtained from serving BS over the backbone network. This type of HO is considered optimized HO. MS information (or MS context) may include static context and dynamic context, where static context consists of all configuration parameters that were acquired during initial NW entry or later, via exchange of information between the BS and MS (for example, all SBC-RSP and REG-RSP parameters, all service flow encodings from DSx message exchanges, etc.) and dynamic context consists of all counters, timers, state machine status, data buffer contents (e.g., ARQ window). Transaction states, which may impact configuration parameters, are considered dynamic context until complete, which by then is considered static context.

**NOTE**—Security context is always considered static context.

Depending on the amount of that information target BS may decide to skip one or several of the following Network Entry steps:

- **Negotiate basic capabilities** (Bit 0 in HO Process Optimization TLV in RNG-RSP is set)
- **PKM Authentication phase** (Bit 1 in HO Process Optimization TLV is set)
- **TEK establishment phase** (Bit 2 in HO Process Optimization TLV is set)
- **REG-REQ message phase** (Bit 9 in HO Process Optimization TLV is set)
- **Unsolicited REG-RSP message phase** (Bit 10 in HO Process Optimization TLV is set)

In case Bit 6 in HO Process Optimization TLV is set, full service and operational state transfer or sharing between serving BS and target BS is assumed (ARQ state, all timers, counters, MAC state machines, CIDs, service flows information and other connection information), so BS and MS do not exchange network reentry messages after ranging before resuming normal operations.

A full list of optimization capabilities is provided in definition of HO Process Optimization TLV (Table 585). When this TLV is included in RNG-RSP sent to an MS performing network re-entry from idle mode, Bit 6 does not refer to any ARQ state (blocks in ARQ window and associated timers). It refers only to SFIDs and related settings (QoS descriptors and CS classifier information) for all Service Flows that the MS had established when it entered idle mode as well as any SAs and their related keying material.
In case network reentry includes Key Request/Reply handshake, the BS shall provide sufficient time to the MS to process received TEK information before moving to next step as specified by HO TEK processing time TLV.

If TLVs for reestablishment of connections (11.7.9) appear in the REG-RSP message or in the REG-RSP encodings TLV in the RNG-RSP message, DSA-REQ/RSP procedure shall not be used for this purpose. In this case, re-establishment of connections starts immediately after REG-RSP (message or TLV in RNG-RSP message); the BS shall provide sufficient time to the MS to process connections information as specified by MS HO connections parameters processing time TLV.

In case Key Request/Key Reply handshake is not omitted, BS shall send REG-RSP, solicited or not. If REG-RSP is not omitted, network reentry process completes with REG-RSP message.

— Termination of MS Context—The final step in HO. Termination of MS Context is defined as serving BS termination of context of all connections belonging to the MS and the context associated with them (i.e., information in queues, ARQ state machine, counters, timers, header suppression information, etc., is discarded).

— HO Cancellation—An MS may cancel HO via MOB_HO-IND message at any time prior to expiration of Resource_Retain_Time interval after transmission of MOB_MSHO-REQ (in case of MS initiated HO) or MOB_BSHO-REQ (in case of BS initiated HO).
The HO process, and its similarity to the initial network entry process, is depicted in Figure 144.

**Figure 144—HO and initial network entry**

### 6.3.21.2.1 Cell reselection

Cell reselection refers to the process of an MS Scanning and/or Association with one or more BS in order to determine their suitability, along with other performance considerations as an HO target. The MS may
incorporate information acquired from a MOB_NBR-ADV message to give insight into available neighbor BSs for cell reselection consideration. The serving BS may schedule scanning intervals or sleep intervals to conduct cell reselection activity. Such a procedure does not involve termination of existing connection to a serving BS. (See Figure 145.)

6.3.21.2.2 HO decision and initiation

An HO begins with a decision for an MS to HO from a serving BS to a target BS. The decision may originate either at the MS, the serving BS, or on the network. The HO may proceed with a notification through either MOB_MSHO-REQ or MOB_BSHO-REQ messages.

If the BS_Controlled_HO flag is set to 0 in the HO type support field of DCD message, the HO notification is recommended, but not required.
If the BS_Controlled_HO flag is set to 1, the HO notification is mandatory unless a drop has been detected by MS as specified in 6.3.21.2.6. The MS shall send MOB_MSHO-REQ only if a triggering condition specified in Trigger TLV or Neighbor BS Trigger TLV has occurred.

Acknowledgement of MOB_MSHO-REQ with MOB_BSHO-RSP is required. After MS transmits MOB_MSHO-REQ, MS shall not transmit any MOB_MSHO-REQ prior to expiration of timer MS_handover_retransmission_timer. MS shall deactivate timer MS_HO_retransmission timer on MS transmission of MOB_HO-IND or MS receipt of MOB_BSHO-RSP.

If an MS that transmitted a MOB_MSHO-REQ message detects an incoming MOB_BSHO-REQ message before the MS_handover_retransmission_timer (see 11.7.12.3) expires, it shall ignore that MOB_BSHO-REQ message. A BS that transmitted a MOB_BSHO-REQ message and detects an incoming MOB_MSHO-REQ message from the same MS shall ignore its MOB_BSHO-REQ. A BS that transmitted a MOB_BSHO-REQ message and detects an incoming MOB_HO-IND message from the same MS shall ignore its own previous request. While a handover is in progress, an MS that has transmitted a MOB_HO-IND message and detects an incoming MOB_BSHO-REQ message from the Serving BS shall ignore that MOB_BSHO-REQ.

When MOB_MSHO-REQ is sent by an MS, the MS may indicate one or more possible target BS. When MOB_BSHO-REQ is sent by a BS, the BS may indicate one or more possible target BSs. The MS may evaluate possible target BS(s) through previously performed scanning and Association activity.

If the Serving BS sends a MOB_BSHO-REQ message to the MS without including a target BSID for handover in the message, the MS should do one of the following:

- Send a MOB_HO-IND message with HO_IND_type set to 0b10 and its preferred target BS included in the message,
- Send a MOB_MSHO-REQ message with its preferred target BS included in the message,
- Send a MOB_HO-IND message with HO_IND_type set to 0b00 and its preferred target BS included in the message,
- Send a MOB_HO-IND message with HO_IND_type set to 0b01 to cancel the handover, or
- Send a MOB_HO-IND message with HO_IND_type set to 0b10 without including its preferred target BS in the message.

Serving BS criteria for recommendation of target BS may include factors such as expected MS performance at potential target BS, BS and network loading conditions, and MS QoS requirements. The serving BS may obtain expected MS performance, BS and network loading conditions at a potential target BS and Basic CID to be used at a potential target BS through the exchange of messages with that BS over the backbone network. The serving BS may negotiate location of common time interval where dedicated initial ranging transmission opportunity for the MS will be provided by all potential target BSs. This information may be included into MOB_BSHO-RSP message, and is indicated by Action Time. The Pre-allocated Basic CID shall be included in the MOB_BSHO-REQ/RSP if the recommended target BS supports Seamless HO mode.

If the Basic CID is pre-allocated at the serving BS, the MS should update its primary management CID and transport CIDs autonomously at the target BS without using CID_update or Compressed CID_update encodings. An MS can derive the new CIDs at a target BS from the Pre-allocated Basic CID by using the Connection identifier descriptor TLV in DCD message. The new primary management CID should be derived by adding ‘m’ to the Pre-allocated Basic CID.

There are two modes for deriving new transport CIDs at a target BS. If autonomous derivation mode is set, the new transport CIDs are derived with ‘m’ and ‘a’ parameters broadcasted in the DCD message. The recommended BS reserves contiguous number (‘a’) of transport CIDs for each MS. An MS can derive the first transport CID by using the equation \( (2m+1) + (\text{Basic CID}–1) \times a \) and it autonomously updates its transport CIDs in ascending order from the first transport CID.
If the number of transport connections of an MS is greater than ‘a’, the block allocation mode should be used. If the block allocation mode is set in MOB_BSHO-REQ/RSP, the first CID at the head of the block shall be included in MOB_BSHO-REQ/RSP. The MS should update all the transport CIDs from the first CID followed by continuous CIDs in the block. A BS may allocate multiple blocks in the MOB_BSHO-REQ/RSP. When the BS allocates multiple blocks, it shall include the first Transport CID and number of Transport CIDs in MOB_BSHO-REQ/RSP for each block.

Dedicated allocation for transmission of RNG-REQ means that channel parameters learned by the MS autonomously, based on information acquired at the time of HO with the target BS or during Association of that BS are considered valid during sufficient time and can be reused for actual network reentry without preceding CDMA ranging. Information such as indicators of link quality in the UL direction learned by the MS during Association may be provided to the serving BS over the backbone.

If Network Assisted HO supported flag is set to “1” in MOB_BSHO-REQ message, MS may perform an HO to any BS among the recommended BSs in MOB_BSHO-REQ without notifying the serving BS of a selected target BS. As an acknowledgement to the MOB_BSHO-REQ message, the MS may send a MOB_HO-IND message with its target BSID set to “0x00000000”.

If Network Assisted HO supported flag is set to “1” in MOB_BSHO-REQ message, MS may perform an HO to any BS among the recommended BSs in MOB_BSHO-REQ without notifying the serving BS of a selected target BS. As an acknowledgement to the MOB_BSHO-REQ message, the MS may send a MOB_HO-IND message with its target BSID set to “0x00000000”.

When the serving BS, transmitted MOB_BSHO-REQ with Network Assisted HO supported flag = 1, receive MOB_HO-IND with target BSID = 0x00000000, it may neglect target BSID included in MOB_HO-IND message.

When the serving BS, transmitted MOB_BSHO-REQ with Network Assisted HO supported flag = 1, receive MOB_HO-IND with target BSID = 0x00000000, it may neglect target BSID included in MOB_HO-IND message.

If the BS_Controlled_HO flag is set to 0 in the HO type support field of the DCD message, MS HO to one of BSs specified in MOB_BSHO-RSP is recommended, but not required. The MS may attempt HO to a different BS that may or may not have been included in MOB_BSHO-RSP.

If the BS_Controlled_HO flag is set to 1, MS handover to one of BSs specified in MOB_BSHO-REQ/RSP is required. An MS may attempt handover to the BS not included in MOB_BSHO-REQ/RSP by sending a MOB_HO-IND indicating the selected BS only if a trigger condition specified in a Trigger TLV or Neighbor BS Trigger TLV has occurred for a target BS not listed in the MOB_BSHO-REQ/RSP.

The MS may respond with MOB_HO-IND with HO_IND_type = 0b10 indicating HO reject if the MS is unable to handover to any of the recommended BSs in the MOB_BSHO-REQ or MOB_BSHO-RSP. If the MS signals rejection of the serving BS instruction to HO through HO_IND_type field in the MOB_HO-IND set value of 0b10 (HO reject), the BS may reconfigure the neighbor BS list and retransmit MOB_BSHO-RSP message including a new neighbor BS list.

An MS may signal rejection of the target BS offered for handover by the serving BS in one of two manners. The MS may send a MOB_HO_IND message with HO_IND_type set to 0b00 (Serving BS release) and include its preferred TBS in the message. In this case the MS doesn't set the T42 timer and the MS departs for the TBS without further negotiation with the SBS. An MS may also signal rejection of the target BS offered by the serving BS by sending MOB_HO_IND message with HO_IND_type set to 0b10 (Handover Reject) and setting the T42 timer. The MS may include its preferred TBS in the message. In this case the MS waits for the SBS to respond with a new MOB_BSHO-RSP or MOB_BSHO-REQ message. If the new TBS is acceptable to the MS, it responds with MOB_HO_IND message with HO_IND_type set to 0b00 (Serving BS Release) and includes the TBS selected from the neighbor list in the message.

In some instances, the BS may need to force the MS to conduct HO. The BS shall include a value of HO operation mode = 1 in either the MOB_BSHO-REQ or MOB_BSHO-RSP to signal to the MS that the MS shall conduct HO. Upon receiving a message with HO operation mode = 1, the MS should treat the HO request as required and shall respond with an HO-IND. MS should send HO-IND with option HO_IND_type = 0b00 indicating commitment to HO unless MS is unable to HO to any of the recommended BSs in the message, in which case MS may respond with HO-IND with option HO_IND_type = 0b10 indicating HO reject and may include the MS preferred target BS for handover. If the BS_Controlled_HO
flag is set to 0 in the HO type support field of the DCD message, an MS required to conduct HO is not restricted to conducting HO to those BS included in the notifying message. In other words, the MS may attempt HO to a different BS that may or may not have been included in either the MOB_BSHO-REQ or MOB_BSHO-RSP. If the BS_Controlled_HO flag is set to 1 in the HO type support field of the DCD message, an MS required to conduct handover is restricted to conducting handover to those BS included in the notifying message. Only in case a triggering condition specified in Trigger TLV or Neighbor BS Trigger TLV has occurred for a target BS not listed in MOB_BSHO-REQ or in the MOB_BSHO-RSP, the MS may attempt handover to the BS by sending a MOB_HO-IND indicating the selected BS. The MS may respond with HO-IND with HO_IND_type = 0b10 indicating HO reject if the MS is unable to handover to any of the recommended BSs in the MOB_BSHO-REQ or MOB_BSHO-RSP.

The serving BS may notify one or more potential target BS over the backbone network of MS intent to HO. The serving BS may also send MS information to potential target BS over the backbone network to expedite HO.

In order to verify the MS can complete the HO preparation phase in time to receive the Fast_Ranging_IE in the target base station (i.e., after action time), the serving BS may grant an unsolicited UL allocation for transmission of MOB_HO-IND message. In this case, the Unsolicited UL Grant for HO-IND flag in MOB_BSHO-REQ/RSP message serving BS should be set to 1. Upon expiration of Handover Indication Readiness Timer, the serving BS should grant an UL allocation to the MS with a size enough for transmission of MOB_HO-IND message.

The serving BS may continue to issue DL and UL allocations to the MS until expiration of Handover Indication Readiness Timer or until MOB_HO-IND with HO_IND_type=0b00 was received or until it received an indication from the target BS (over the backbone network) that MS successfully completed its HO attempt or until it decides that the MS is no longer available.

The MS that sent MOB_HO-IND with option HO_IND_type = 0b00 indicating commitment to HO and intent to release the serving BS, shall not be expected to monitor serving BS DL traffic after transmission of the MOB_HO-IND message.

6.3.21.2.3 HO cancellation

After an MS or BS has initiated an HO using either MOB_MSHO-REQ or MOB_BSHO-REQ message, the MS may cancel HO at any time.

The cancellation shall be made through transmission of a MOB_HO-IND message that signals the HO cancel option (HO_IND_type = 0b01). If the MS is capable of detecting that the MOB_HO-IND message has been lost (through some implementation specific mechanism, for example by use of a timer), the MS may react as if it detected a drop during HO and apply the procedures specified in 6.3.21.2.6.

When MS transmits and serving BS receives MOB_HO-IND message with the HO cancel option (HO_IND_type = 0b01) during Resource Retain Time (when Resource Retain Flag = 1), regardless of MS attempt at HO, the MS and serving BS shall resume normal operation communication.

6.3.21.2.4 Fast ranging

For the purpose of expediting NW re-entry of the MS with the target BS, the serving BS may negotiate with target BS allocation of a non-contention-based ranging opportunity for the MS, i.e., an unsolicited UL allocation for transmission of RNG-REQ message. The agreed time shall take into account the Handover Indication Readiness Timer (see 11.7.12.6) and BS Switching Timer (see 11.7.12.7).

The MS may learn the required ranging parameters at the target BS at the time of HO. Ranging parameters are based on PHY parameters of the serving BS at the time of HO indication and PHY parameters acquired
from the target BS during or prior to HO, or during scanning of target neighbor BSs and optionally via association.

The serving BS should indicate the time of the fast (i.e., non-contention-based) ranging opportunity, negotiated with the potential target BSs, via Action Time field in the MOB_BSHO-REQ/RSP message.

The target BS(s) shall indicate the fast ranging allocation in the UL-MAP via Fast_Ranging_IE (see 8.3.6.3.9, and 8.4.5.4.19 Fast ranging Information Element). The Action time + T55 provides a bounded interval during which the MS may expect to receive Fast_Ranging_IE.

T55 starts in the frame after the MS expects to receive Fast_Ranging_IE, derived by Action Time.

Upon expiration of this timer, the MS shall not expect the Target BS to grant an UL allocation via Fast_Ranging_IE and shall release the HO_ID.

### 6.3.21.2.5 Termination with the serving BS

After the HO request/response handshake has completed, the MS may begin the actual HO. At some stage during the HO process, the MS terminates service with the serving BS. This is accomplished by sending a MOB_HO-IND message with the HO_IND_type value indicating serving BS release.

If the HO_IND_type field specifies serving BS release, the BS shall start the Resource retain timer from value Resource_Retain_Time provided by BS in REG-RSP, BSHO-REQ, or BSHO-RSP messages. The serving BS shall retain the connections, MAC state machine, and PDUs associated with the MS for service continuation until the expiration of Resource retain timer. Regardless of Resource retain timer, the serving BS shall remove MAC context and MAC PDUs associated with the MS upon reception of a message from the target BS, over the backbone network, indicating MS Network Attachment at target BS.

If the serving BS determines to retain the connection information of an MS that has sent MOB_HO-IND with HO_IND_type = 0b00 and begun the actual HO, this connection information may be used by the MS in order to perform an expedited reentry operation with target BS or the serving BS. The serving BS shall notify the MS of retention of MS connection information through Resource Retain Flag in MOB_BSHO-RSP message or MOB_BSHO-REQ message during HO request/response handshake operation. If Resource Retain Flag = 1 and Resource Retain Time is not included as a TLV item in the message, then the serving BS and MS shall use the System Resource Retain Time timer.

### 6.3.21.2.6 Drops during HO

A drop is defined as the situation where an MS has stopped communication with its serving BS (either in the DL or in the UL) before the normal HO sequence outlined in Cell Selection and Termination with the serving BS has been completed.

An MS can detect a drop by its failure to demodulate the DL, or by exceeding the RNG-REQ retries limit allowed for the periodic ranging mechanism. A BS can detect a drop when the Number of retries limit allowed on inviting ranging requests for the periodic ranging mechanism is exceeded.

When the MS has detected a drop during network reentry with a target BS, it may attempt network reentry with its preferred target BS as through Cell Reselection (see 6.3.21.2.1), which may include resuming communication with the serving BS by sending MOB_HO-IND message with HO_IND type = 0b01 (HO cancel) or performing network reentry at the serving BS.

The network reentry process at the serving BS is identical to the network reentry process at any other target BS, both for the serving BS and for the MS. If the serving BS has discarded the MS context, the network
re-entry procedure shall be the same as full network reentry with HO optimization rules and scenarios defined in 6.3.21.2.10.

MS shall perform CDMA ranging with target BS using codes from HO codes domain.

Upon the target BS’s sending RNG-RSP with Ranging Status = success, the target BS shall provide CDMA ALLOC IE with appropriate UL allocation for RNG-REQ from MS. MS shall send RNG-REQ with MAC address and HMAC/CMAC. The target BS may now identify that HO attempt by MS was not coordinated with the serving BS and may request all relevant MS context from the serving BS. Using this information, the target BS shall now send RNG-RSP with HO process optimization bitmap and network reentry may continue as in the typical, nondrop case.

When the serving BS has detected a drop, it shall react as if a MOB_HO-IND message has been received with HO_IND_type indicating serving BS release.

### 6.3.21.2.7 Network entry/reentry

Unless otherwise indicated in this subclause, MS mobile network entry/reentry is processed according to 6.3.9.

Note that in this section, “target BS” may reference the BS that was the serving BS at the time the handover was initiated.

An MS and a target BS shall conduct ranging per 6.3.9.5 except when dedicated ranging opportunity is available, in which case, the procedure described in 6.3.21.2.4 shall be employed. For identification of the MS, RNG-REQ message may include MS MAC Address or HO_ID (if assigned in MOB_BSHO-REQ or MOB_BSHO-RSP). The target BS shall assign to the MS Basic CID and Primary CID in the RNG-RSP management message.

The MS shall signal the target BS of a current HO attempt by including a serving BSID TLV and Ranging Purpose Indication TLV with Bit 0 set to 1 in the RNG-REQ management message. The MS shall not include a Ranging Purpose Indication TLV in the RNG-REQ management message unless actually in the process of conducting an HO, location update, or network reentry from idle mode attempt.

If an MS RNG-REQ includes a serving BSID and Ranging Purpose Indication TLV with Bit 0 set to 1, and the target BS had not previously received MS information over the backbone network, then the target BS may make an MS information request of the serving BS over the backbone network and the serving BS may respond. Regardless of having received MS information from the serving BS, the target BS may request MS information from another network entity via the backbone network.

Network reentry proceeds per 6.3.9, except as may be shortened by the target BS’s possession of MS information obtained from the serving BS over the backbone network, and except 6.3.9.10 to 6.3.9.12, which may be postponed until after the MS reenters the network.

To notify an MS seeking HO of possible omission of reentry process management messages during the current HO attempt (due to the availability of MS service and operational context information obtained over the backbone network), the target BS shall place in RNG-RSP an HO Process Optimization TLV indicating which reentry management messages may be omitted. The MS shall complete the processing of all indicated messages before entering normal operation with target BS.

As indicated in the HO Process Optimization TLV settings, the target BS may elect to use MS service and operational information obtained over the backbone network to build and send unsolicited SBC-RSP and/or REG-RSP management messages to update MS operational information, or to include this information into TLV items in the RNG-RSP. If the target BS sends an unsolicited SBC-RSP or unsolicited REG-RSP
message and the MS sends the corresponding SBC-REQ (REG-REQ) message, the BS may ignore only the first corresponding REQ management message received. The MS is not required to send the complimentary REQ management message if it receives an unsolicited SBC-RSP or unsolicited REG-RSP management message prior to MS attempt to send the corresponding REQ management message. Target BS reentry unsolicited response management messages may be grouped into the same DL frame transmission with the RNG-RSP. However, unsolicited SBC-RSP and unsolicited REG-RSP may not be grouped together into the same DL frame transmission when the PKM-REQ/RSP management message process is required. For a security keying process that has not been determined to be omitted in the HO Process Optimization TLV settings, if MS RNG-REQ includes an serving BSID and Ranging Purpose Indication TLV with Bit 0 set to 1, and target BS has received a message over the backbone network containing MS information, MS and target BS shall use the embedded TLV PKM-REQ information and the reauthorization process as defined in 7.2. When the HO Process Optimization TLV is included in RNG-RSP sent to an MS performing network re-entry from idle mode, Bit 6 does not refer to any ARQ state (blocks in ARQ window and associated timers). It refers only to SFIDs and related settings (QoS descriptors and CS classifier information) for all Service Flows that the MS had established when it entered idle mode as well as any SAs and their related keying material.

If the MS finishes the re-entry registration procedure by successfully receiving either an unsolicited REG-RSP message or a RNG-RSP message including REG-RSP specific TLV items, the MS shall send a notification of MS’s successful reentry registration when Bit 12 of the HO Process Optimization TLV in the RNG-RSP message is set to one (see 6.3.21.2.7).

When optimization bit 8 is cleared (=0) the BS shall send an unsolicited SBC-RSP management message with updated capabilities information.

When optimization bit 10 is cleared (=0) the BS shall send an unsolicited REG-RSP management message with updated capabilities information.

When optimization bit 12 is set, the MS may use any uniquely identifiable indication as notification of MS’s successful re-entry registration. The following are examples of such indications:

- MS transmits data in unsolicited UL grant by the target BS (i.e., MS has pending UL data) using newly assigned transport CID.
- MS transmits Bandwidth request header of type 0b001 with BR per desired BW when MS has pending UL data using newly assigned transport CID.
- MS transmits Bandwidth request header of type 0b000 or 0b001 with BR=0 when MS has no pending UL data using newly assigned basic CID.
- MS transmits any MAC signaling header type I with its CID field set to a newly assigned transport or basic CID and (if included) its incremental BR field set to 0.
- MS transmits HARQ ACK using the ACKCH slot assigned by the target BS.
- MS transmits CQI code using the CQICH slot assigned by the target BS.

When, during capabilities negotiation, MS specifies that it supports IEEE 802.16 security, if the normal PKM initial network entry process as defined in 7.2 is to be abridged or omitted, then the MS shall include the HMAC/CMAC Tuple as the last message item in the RNG-REQ management message using the AK and key sequence number derived for use on the target BS. If the required HMAC/CMAC Tuple is invalid or omitted in the RNG-REQ management message, then the full PKM REQ/RSP sequence shall be completed and cannot be omitted. The target BS shall include a valid HMAC/CMAC Tuple as the last message item in the RNG-RSP if it instructs the MS, through the HO Process Optimization TLV, that the PKM-REQ/RSP sequence may be omitted. If the HO Process Optimization TLV Bit 1 included in the RNG-RSP is set to 0, the HMAC/CMAC Tuple is not attached to the RNG-RSP message.
EAP phase is agnostic to HO, thus it may start at the serving BS and continue at the target BS. EAP packet drops may occur during HO interruption time and it should be handled by EAP state machines in the participating entities (supplicant and authenticator).

If MS RNG-REQ includes a serving BSID and Ranging Purpose Indication TLV with Bit 0 set to 1, and target BS has received a message over the backbone network containing MS information, the target BS may use MS service and operational information obtained over the backbone network to build and send a REG-RSP message or a RNG-RSP message with REG-RSP encodings TLV that includes service flow remapping information in SFID, New_CID, and Connection_Info TLVs.

During HO, the target BS may notify the MS, through the Bit 9 MS DL data pending element of the HO Process Optimization TLV item in RNG-RSP, of post-HO re-entry MS DL data pending. Upon MS successful re-entry at the target BS, now the new serving BS, the new serving BS can transmit forwarded data (called “pre-HO pending MS DL data”) to the MS. After completing reception of any HO pending MS DL data retained and forwarded, the MS may re-establish IP connectivity and the new serving BS may send a message over the backbone network to request the old serving BS or other network entity to stop forwarding pre-HO pending MS DL data.

Network entry/reentry process completes with establishment/reestablishment of provisioned connections.

When the target BS has detected a failed HO entry/re-entry attempt, it may inform the serving BS of HO failure through a message over the backbone network indicating Handover Failure.

6.3.21.2.8 MS-assisted coordination of DL transmission at target BS for HO

If both the serving BS and the target BS involved in the HO process can support continuity of ARQ- or SDU_SN-enabled connections, the BSs and the MS may perform MS-assisted coordination of DL transmission during HO as described in this subclause. The target BS may signal to the MS on the intention to apply this procedure using Bit 11 of HO Process Optimization flag in the RNG-RSP message.

Once the MS has successfully completed HO to the target BS (now the new serving BS), to maintain continuity of transmission to the MS between the old and new serving BSs, the last successfully received information unit needs to be identified to the new serving BS. Depending on whether the connection is ARQ-enabled or ARQ-disabled, the identity of the next information unit can be given by the ARQ block sequence number or the MAC SDU sequence number respectively.

MS can optionally support the feedback of the ARQ block sequence number or the virtual MAC SDU sequence number after the MS has successfully completed HO to the target BS. The capability and the support for each connection are defined in the REG-REQ/RSP and DSA-REQ/RSP TLVs respectively.

— For ARQ-enabled, the ARQ block sequence number is already available at the MS.
— For ARQ-disabled, the following procedures shall be performed by the BS and the MS: the old serving BS shall include a SDU SN extended subheader at least once every $2^p$ MAC PDUs, where $p$ is specified in the MAC header and extended subheader support TLV (11.7.21). Upon transmitting MOB_BSHO-RSP (in response to receiving MOB_MSHO-REQ, in case of MS-initiated HO) or upon transmitting MOB_BSHO-REQ (in case of BS-initiated HO), if the old serving BS continues transmission of data to the MS, it shall include SDU SN extended subheader in MAC PDU at least once before “Estimated HO time” (the first time that MS is expected to communicate with the target BS). The MS shall maintain MAC SDU sequence number based on the information received from the BS. When the MS receives a MAC PDU without SDU SN extended subheader, the MS shall increment the MAC SDU sequence number by one for every SDU received. When the MS receives MAC SDU sequence number from the BS, it shall reset the MAC SDU sequence number to the value included in SDU SN extended subheader.
Upon completion of network reentry, the target BS (now the new serving BS) should provide UL allocation for the MS sufficient for transmission of SN report MAC header with LSBs of the sequence number(s) of ARQ block or virtual MAC SDU number. After reception of SN report MAC header, the BS shall resume transmission of the data of the corresponding DL service flow starting from MAC SDUs pointed by the sequence number. At the completion of network reentry, the MS shall send SN report MAC headers (as described in 6.3.2.1.2.1.7) that include the next ARQ Block (or virtual MAC SDU) sequence number that it is expecting for each of its connections that have SN feedback enabled. The MS shall send the sequence number in numerical ascending order of the values of the SFIDs values. The new serving BS may send the SN request extended subheader to explicitly request an MS to send additional SN report header. After receiving the SN request extended subheader, the MS shall send the requested SN report header. The new serving BS provides allocation through UL-MAP IE for the MS to send the additional SN report header.

6.3.21.2.8.1 Context management during optimized HO

The MS may use any context at the target BS (static and dynamic) that was acquired with the serving BS if it supports optimized HO. However, some of the dynamic context may change to accommodate proper NW re-entry operation at the target BS.

The MS shall retain its context with the serving BS, if HO cancellation is supported by both the serving BS and the MS. Some of the dynamic context may change to accommodate proper operation upon HO cancellation.

The following specifies the expected settings of the MS context during HO (the context is categorized for simplicity of depiction):

6.3.21.2.8.1.1 BS PHY settings

Knowledge about the BS maintained by MS (e.g., FFT size, BW, CP, frame size, DL frequency): MS may maintain serving BS PHY settings until expiration of resource retain timer or until successful HO to the target BS.

6.3.21.2.8.1.2 BS Channel descriptor settings

Knowledge about the BS maintained by MS: MS may maintain serving BS Channel descriptor settings until expiration of resource retain timer or until successful HO to the target BS.

Target BS channel descriptor settings are acquired by MS via neighbor advertisement, in association with Configuration Change Count (CCC) value.

During the HO, the MS shall verify that the DCD/UCD configuration change counts (CCCs) of the target BS (according to DL/UL-MAP) are identical to DCD/UCD CCCs as they appeared in MOB_NBR-ADV message of the serving BS. Then target BS channel descriptor settings shall be used by the MS during Network Re-entry. Otherwise, MS shall wait until it receives DCD/UCD or cancel HO or perform HO to another target BS.

T1 and T12 are reset upon successful match.

6.3.21.2.8.1.3 Ranging settings

MS context with Serving BS: All timers and associated retry counters are reset (T2, T3, T4 etc).

MS context with Target BS: All timers and associated retry counters are reset (T2, T3, T4 etc).

T2 is restarted upon obtaining both DCD and UCD.
If Fast_ranging_IE is used, MS may perform autonomous ranging or use parameters acquired through association (if supported). In case of autonomous ranging failure, MS may perform CDMA ranging with HO codes or cancel HO or attempt HO to another target BS.

MS shall restart T4 upon successful ranging completion (fast ranging or CDMA ranging).

### 6.3.21.2.8.1.4 Basic capabilities settings:

MS context with Serving BS: Maintained with resource retain timer.

MS context with Target BS: If static context is shared and basic capabilities of the target BS differ from the serving BS, then the target BS shall convey updated basic capabilities (only TLVs with the different capabilities). The target BS instructs how basic capabilities shall be updated via HO process optimization TLV settings: If bit 0=0, then MS shall send SBC-REQ message (to which the target BS shall respond with SBC-RSP message). If bit 0=1 AND bit 8=0, then MS shall await an unsolicited SBC-RSP message.

In case of full optimized HO, the target BS should not update any basic capabilities.

### 6.3.21.2.8.1.5 Registration settings

MS context with Serving BS: Maintained with resource retain timer.

MS context with Target BS: If static context is shared between the serving BS and the target BS and capabilities of the target BS, as defined thru registration, differ from the serving BS, then the target BS shall convey updated capabilities (only TLVs with the different capabilities). The target BS instructs how registration capabilities shall be updated via HO process optimization TLV settings: If bit 7=0, then MS shall send REG-REQ message to which the target BS shall respond with REGC-RSP message. If bit 7=1 AND bit 10=0, then MS shall await an unsolicited REG-RSP TLV.

In case of full optimized HO, the target BS should not update any registration settings (excluding CIDs, SAIDs).

### 6.3.21.2.8.1.6 Service flows settings

#### 6.3.21.2.8.1.6.1 Service flows—static context

Service flows configuration is considered static context.

MS context with Serving BS: Maintained with resource retain timer.

MS context with Target BS: When static context is shared between the serving BS and the target BS, then all service flow parameters remain unchanged (except for CIDs and SAIDs that may change).

When service flow parameters at the target BS are different than the serving BS, the target BS shall use CID update and or SAID update as part of the REG-RSP encodings TLV in RNG-RSP, or DSC-REQ messages upon HO completion, to change the configuration of the connections, as required.

#### 6.3.21.2.8.1.6.2 Service flows—dynamic context, non-ARQ enabled connections

MS context with Serving BS: SDU fragments are maintained with resource retain timer.

MS context with Target BS:

- **Downlink:** Either continuation at fragment-level or SDU-level is allowed.
Continuation at fragment-level: The target BS may transmit the fragment, following the last SDU fragment that was transmitted by the serving BS. For example: If a SDU consists of fragments A and B, and due to HO, the serving BS transmitted fragment A but not B, then the target BS shall continue from fragment B (not retransmit fragment A).

Continuation at SDU-level: The target BS may retransmit last outstanding SDU or drop it and continue to next complete SDU.

Upon HO completion, if commanded by the target BS (via bit 12=1), the MS shall transmit SN_REPORT header with last received SDU SN per SDU SN-enabled CID.

Uplink: If bit 6 is set to 1, the MS shall transmit to the target BS the fragment after the last transmitted fragment at the serving BS. If bit 6 is set to 0, the MS shall continue at the SDU level.

6.3.21.2.8.1.6.3 Service flows—dynamic context, ARQ enabled connections

MS context with Serving BS: ARQ window contents shall be maintained with resource retain timer. The serving BS may pause or reset timers associated with ARQ Blocks. MS shall continue the timers.

MS context with Target BS:

If bit 6=0, ARQ window shall be reset automatically by transmitters (MS and target BS), without explicit ARQ_reset. Regardless, MS and/or target BS may send ARQ_reset.

If bit 6=1, then the following behavior is expected upon HO completion:

— ARQ window contents shall be transferred from the serving BS to the target BS. Target BS shall continue BSN numbering from serving BS (in both DL and UL). Target BS may pause or reset timers associated with ARQ Blocks.
— The Target BS shall continue the BSN numbering from the serving BS for both DL and UL connections.

Downlink:

— If MS received DISCARD message from the serving BS but couldn't reply with acknowledgement, the MS shall send the acknowledgement to the target BS. The MS may send the acknowledgements immediately after HO completion or may postpone it depending on the state of its internal timers.
— The Target BS shall never transmit the ARQ blocks up to the one specified in the last DISCARD message from the serving BS. The target BS may re-transmit the DISCARD message (first transmitted by the serving BS) immediately after HO or it may postpone the retransmission up until ARQ_RETRY_TIMEOUT after HO completion. If the target BS does not receive the acknowledgement for the discarded blocks it shall retransmit DISCARD message at the intervals equal to ARQ_RETRY_TIMEOUT until it receives the acknowledgement.
— If the MS had successfully received an ARQ block from the serving BS but could not send the acknowledgement to the serving BS, the MS shall send the acknowledgement to the target BS. The MS shall send the acknowledgements immediately after HO completion or may postpone it depending on the state of its internal timers.
— If the serving BS has transmitted an ARQ block to the MS, but it was not acknowledged by the MS, the target BS shall start retransmitting the ARQ block either immediately after HO completion or later, depending on the state of the internal timers until it receives the acknowledgement from the MS.
— If the serving BS has transmitted an ARQ block to the MS, and it was acknowledged by the MS, the target BS shall not transmit it again.
Uplink:

— The MS assumes that the network is capable of re-assembling the SDU parts, which may have been received by different Base Stations.
— If the serving BS has successfully received an ARQ block from the MS but could not reply with acknowledgement to the MS, the target BS shall send the acknowledgement to the MS. The target BS may send the acknowledgements immediately after HO completion or may postpone it depending on the state of its internal timers.
— If the MS has been transmitted an ARQ block to the serving BS, but did not receive acknowledgement from the serving BS, the MS shall start retransmitting it to the target BS either immediately after HO completion or later, depending on the state of the internal timers until it receives the acknowledgement from the MS.
— If the MS has transmitted an ARQ block to the serving BS, and received acknowledgement from the serving BS, the MS shall not transmit it again upon HO completion.

6.3.21.2.8.1.6.4 Service flows - dynamic context, HARQ enabled connections

MS context with Serving BS: All dynamic HARQ context is reset in both DL and UL. HARQ data buffers are purged, buffered softbits are cleared and AI_SN on all ACIDs are set to zero.

MS context with Target BS: All dynamic HARQ context is reset in both DL and UL. HARQ data buffers are purged, buffered softbits are cleared and AI_SN on all ACIDs are set to zero. Regardless of bit 6, HARQ ACID and channel mapping is maintained (unique per service flow). PDU SN (if enabled) shall be reset and then follow the rules of service flow state for non-ARQ and ARQ connections as described above.

6.3.21.2.8.1.6.5 Outstanding bandwidth requests

MS context with Serving BS: Reset.

MS context with Target BS: Reset (not transferred from the serving BS). MS shall transmit bandwidth request of remaining (outstanding) bytes.

6.3.21.2.8.1.6.6 Security settings

MS context with Serving BS: Maintained with resource retain timer,

MS context with Target BS: Context is handled per bit 1 and bit 2 settings.

Bit 1=0 AND bit 2=0: Perform re-authentication and SA-TEK 3-way handshake. BS shall not include SA-TEK-Update TLV in the SA-TEK-Response message. In addition, the RNG-RSP message does not include SA-TEK-Update TLV.

Bit 1=0 AND bit 2=1: Not used. MS shall silently ignore RNG-RSP message.

Bit 1=1 AND bit 2=0: SA-TEK-Update TLV is included in the RNG-RSP message and updates the TEKS for all the SAs.

Bit 1=1 AND bit 2=1: Re-authentication is not performed. The RNG-RSP message does not include SA-TEK-Update TLV. All the TEKs received from the serving BS are reused. All PMK timers are maintained.

SAID update:

When re-authentication is not required and SAID_update TLV is excluded from the RNG-RSP message during network re-entry, it means that SAID value(s) shall be the same value(s) as the value(s) used in
previous serving BS and the value of Primary SAID will be implicitly updated because MS and BS use the
same value as that of Basic CID.

Regardless, the target BS may include SAID_update TLV within RNG-RSP message by including
compound REG-RSP encodings TLV.

When target BS allocates SAID (excluding the primary SAID) during handover re-entry, the target BS
should allocate the new SAID with same value of SAID that was used in serving BS in order to avoid
possible mismatch of old SAID.

For more information on security context management during HO, see 6.3.21.2.8, HO during re-
authentication.

6.3.21.2.8.1.6.7 Power Saving Class settings

MS context with Serving BS: Maintained with resource retain timer

MS context with Target BS:

All Power Saving Class related configurations, timers and states are reset.

The MS shall locally deactivate all active Power Saving Classes to perform HO. The MS and the serving BS
shall not initiate new sleep transactions during HO negotiation. If there is some ongoing MS-initiated sleep
transaction when HO negotiation starts and the MS receives the MOB_SLP-RSP message before
transmitting the MOB_HO-IND message, the MS shall successfully complete this transaction accepting all
PSC definitions from MOB_SLP-RSP message, but shall not activate any PSCs. If the MOB_SLP-RSP
message is not received before handover to the target BS or before expiration of timer T43, the MS shall
terminate the sleep transaction. If the serving BS receives MOB_SLP-REQ message after HO negotiation
has started and before HO cancellation, the serving BS shall reject PSC definition(s) and shall not send
MOB_SLP-RSP message.

The MS may reenter sleep mode, upon HO completion at the target BS, by transmitting a MOB_SLP-REQ
message, which shall include all requested Power Saving Class configurations. If the MS cancels HO and
returns to normal operation with its previous serving BS, it may re-enter sleep mode by activating retained
PSC configurations. The MS should not include the definition of a retained Power Saving Class in a
MOB_SLP-REQ message after HO cancellation unless some sleep transaction was terminated by the MS
during HO.

6.3.21.2.8.1.7 Scanning—dynamic and static context

MS scanning context with Serving BS: Reset.

MS scanning context with Target BS: Reset.

The MS shall terminate all scanning activity including the outstanding scanning negotiation and group of
scanning and/or reporting intervals to perform HO.
6.3.21.2.9 HO process

Figure 146 shows the process of an MS initiating HO with the BS.

Figure 146—MS initiating HO with the BS
Figure 147 shows the process of an MS waiting for a response from the BS; in addition, it presents the case in which the MS has decided to stop the HO in the middle of the process.

Figure 147—Locally Initiated Transaction MOB_BSHO-RSP Pending state flow diagram
Figure 148 shows the process of an MS following a rejecting of the HO and ensuring that the MOB_HO-IND message was received by the BS (by expiration of T42 timeout). While waiting, if new HO process is required, the MS shall stop T42 timer without waiting.

Figure 148—Typical MS Listening state flow diagram
Figure 149 shows the process of an MS receiving a MOB_BSHO-REQ message from the BS; in addition, it presents the case in which the MS has decided to stop the HO in the middle of the process.

![State Flow Diagram](image)

**Figure 149—MS state flow diagram for remotely initiated MOB_BSHO-REQ**

### 6.3.21.2.10 HO optimization rules and scenarios

The bitmap of the HO process optimization TLV in RNG-RSP message during HO shall be set according to the following rules:

Non-managed SS (i.e., SSs that do not support secondary management connection)

- HO process optimization bit 3 = 1 (omit DHCP)
- HO process optimization bit 4 = 1 (omit time-of-day acquisition)
- HO process optimization bit 5 = 1 (omit TFTP phase)
- All other bits: don’t care (i.e., do not depend on SS management support)

**SBC-REQ/RSP consistency:**
When HO process optimization bit 8 is set to 0, HO process optimization bit 0 shall be set to 1

**REG-REQ/RSP consistency:**
When HO process optimization bit 10 is set to 0, HO process optimization bit 7, shall be set to 1
The bitmap of the HO process optimization TLV in RNG-RSP message during HO shall be set according to the following scenarios:

- **Full optimized HO scenario**
  Both static and dynamic context are shared between the serving BS and the target BS.
  HO process optimization TLV settings:
  - HO process optimization bit 0 = 1
  - HO process optimization bit 1 = 1
  - HO process optimization bit 2 = 1
  - HO process optimization bit 6 = 1
  - HO process optimization bit 7 = 1
  - HO process optimization bit 8 = 1
  - HO process optimization bit 10 = 1
  - All other bits, except reserved bits = Don’t care (i.e., not dependant on optimization case)

- **Full optimized HO scenario with TEK updates**
  Both static and dynamic context are shared between the serving BS and the target BS.
  HO process optimization TLV settings:
  - HO process optimization bit 0 = 1
  - HO process optimization bit 1 = 1
  - HO process optimization bit 2 = 0 (When SA-TEK Update TLV is sent in RNG-RSP)
  - HO process optimization bit 6 = 1
  - HO process optimization bit 7 = 1
  - HO process optimization bit 8 = 1
  - HO process optimization bit 10 = 1
  - All other bits, except reserved bits = Don’t care (i.e., not dependant on optimization case)

- **Optimized HO with static context sharing scenario**
  Static context only (i.e., no dynamic context) is shared between the serving BS and the target BS.
  HO process optimization TLV settings:
  - HO process optimization bit 0 = 1
  - HO process optimization bit 1 = 1
  - HO process optimization bit 2 = 0 (When SA-TEK Update TLV is sent in RNG-RSP)
  - HO process optimization bit 6 = 0
  - HO process optimization bit 7 = 1
  - HO process optimization bit 8 = 1
  - HO process optimization bit 10 = 1
  - All other bits, except reserved bits = Don’t care (i.e., not dependant on optimization case)

- **Full network entry without traffic IP address refresh (no optimization):**
  No context sharing between the serving BS and the target BS.
  HO process optimization TLV settings:
  - HO process optimization bit 0 = 0
  - HO process optimization bit 1 = 0
  - HO process optimization bit 2 = 0
  - HO process optimization bit 6 = 0
  - HO process optimization bit 7 = 0
  - HO process optimization bit 8 = 1
  - HO process optimization bit 10 = 1
  - HO process optimization bit 11 = 0
  - HO process optimization bit 12 = 0
  - HO process optimization bit 13 = 0
  - All other bits, except reserved bits = Don’t care (i.e., not dependant on optimization case)
— Full network entry with traffic IP address refresh (no optimization):
  No context sharing between the serving BS and the target BS.
  HO process optimization TLV settings:
  — HO process optimization bit 0 = 0
  — HO process optimization bit 1 = 0
  — HO process optimization bit 2 = 0
  — HO process optimization bit 6 = 0
  — HO process optimization bit 7 = 0
  — HO process optimization bit 8 = 1
  — HO process optimization bit 10 = 1
  — HO process optimization bit 11 = 0
  — HO process optimization bit 12 = 0
  — HO process optimization bit 13 = 1
  — All other bits, except reserved bits = Don’t care (i.e., not dependant on optimization case).

In the full network entry scenarios the RNG-RSP message carrying the HO process optimization TLV above shall not be signed with HMAC/CMAC.

6.3.21.2.11 Seamless HO

In addition to Optimized HO, MS and BS may perform Seamless HO to reduce HO latency and message overhead. The capability of Seamless HO is negotiated by REG-REQ/RSP message (see 11.7.12.5).

If any authorization policy, except “No Authorization,” is negotiated between MS and BS, seamless HO also requires support for counter-based TEK Generation for HO (see 7.2.2.2.6).

To perform Seamless HO for an MS in the serving BS, the target BS(s) and the MS shall support Seamless HO as well. A BS supporting Seamless HO shall include the Connection identifier descriptor TLV in the DCD message. In Seamless HO, a target BS calculates Primary management CID, Secondary management CID, and Transport CIDs for an MS by using the descriptor.

During Seamless HO, a serving BS shall include the Pre-allocated Basic CID in MOB_BSHO-REQ/RSP for an MS. When a BS pre-allocates a Basic CID to an MS during Seamless HO, the primary management CID is allocated autonomously without explicit assignment in the message. If \( n \)-th Basic CID within the range \( 0x0001 – m \) (see Table 558) is allocated, the \( n \)-th Primary Management CID in the range \( m + 1 – 2m \) shall be allocated to the same MS in ascending order. The Primary management CID is derived by adding \( m \) to the Basic CID, where \( m \) is given by Connection identifier descriptor in DCD message.

When a BS assigns Pre-allocated Basic CID, it also reserves a block of continuous transport CIDs, where the number of CIDs is \( a \) within the range \( 2m + 1 – 0xFE9F \) (see Table 558). The block of continuous transport CIDs starts from the \( 2m + 1 \) and each block consists of continuous \( a \) number of CIDs, where \( a \) is given by Connection identifier descriptor in DCD message.

Once CIDs have been pre-allocated, the BS shall determine and indicate whether it will perform Seamless HO by including the Seamless HO mode flag into MOB_BSHO-REQ/RSP message. When the MS receives MOB_BSHO-REQ or MOB_BSHO-RSP message with the Seamless HO mode flag set to 1 (indicates support), the MS can perform Seamless HO by transmitting a HO-IND message including the BSID of a BS among the recommended BSs that indicate support for seamless HO (i.e., a BS for which the Seamless HO mode flag was set to 1 in the BSHO_REQ/RSP message). If the MS transmits a HO-IND message including the BSID of any BS other than the recommended BSs which indicate support for Seamless HO then Seamless HO is not applied for this BS.
The MOB_BSHO-REQ or MOB_BSHO-RSP message may contain a specific action time. If this value is specified, pre-allocated CIDs are valid at the target BS after the time specified by the action time. A value of 0 indicates that the pre-allocated CIDs are already valid and MS may initiate Seamless HO at anytime.

During seamless HO, the target BS (T-BS) may allocate downlink and uplink resource for the MS before the RNG-REQ/RSP message transaction, as shown in Figure 150.

![Figure 150—Example of a seamless HO dialog](image-url)

During Seamless HO, the MS is required to initiate the RNG-REQ/RSP message transaction by sending a RNG-REQ message before the deadline specified by the “Seamless HO Ranging Initiation Deadline” attribute included in BSHO-REQ/RSP message during handover preparation. The time is measured from the time the BSHO-REQ/RSP message is transmitted. If the Target BS does not receive a RNG-REQ message from the MS within the deadline defined by the “Seamless HO Ranging Initiation Deadline” attribute, the Target BS considers the seamless HO as failed and stops allocating bandwidth to the MS. It is recommended that the BS allows time equal to T3 timer (Table 554) before it reuses the CIDs that were allocated to the MS. The MS considers the seamless HO as failed if it does not transmit RNG-REQ message before the deadline. If the MS transmits RNG-REQ within the deadline, it may still consider the HO as failed if it does not receive a RNG-RSP within T3 after the last transmission or retransmission of RNG-REQ that was performed within the deadline. When the MS considers the seamless HO as failed, it invalidates the pre-allocated CIDs. In all cases, even when the RNG-REQ/RSP message transaction is initiated before the deadline, the Seamless HO is considered failed if the RNG-REQ/RSP procedure fails.

When data packets are exchanged before the RNG-REQ/RSP transaction is completed, the recipient (MS or BS) should store the received data packets and not release them to the upper layers until the sender is authenticated. If the data packets belong to a service flow associated with an SA that supports data authentication (as indicated by the data authentication algorithm identifier in the cryptographic suite of the SA) the receiver can authenticate the sender by verifying that the ciphertext authentication code included in
each data packet was produced with the TEK associated with this SA. If the data packets belong to a service flow associated with an SA that does not support data authentication the receiver can authenticate the sender when the RNG-REQ/RSP transaction completes successfully. In all cases, if the sender is authenticated, the decrypted data packets are released to the upper layer in the recipient, and if the sender is not authenticated the data packets are discarded.

The RNG-REQ/RSP transaction for Seamless HO is shown in Figure 150. The MS shall initiate the RNG-REQ/RSP transaction by transmitting a RNG-REQ message to the target BS before the deadline specified by the “Seamless HO Ranging Initiation Deadline” attribute included in BSHO-REQ/RSP message during handover preparation. The RNG-REQ message shall include Basic CID, CMAC_KEY_COUNT and a valid HMAC/CMAC tuple. Ranging Purpose Indication TLV with Bit 2 set to 1, but not include MS MAC address or previous serving BSID. When BS receives the RNG-REQ message, BS shall respond to the RNG-REQ message by transmitting RNG-RSP message with valid HMAC/CMAC tuple. The RNG-RSP message shall include Basic CID but does not need to include any CID update TLV or SA-TEK-Update TLV for unicast connections.

When MS receives the RNG-RSP message from the target BS, the target BS becomes the serving BS of the MS and the MS shall transmit a BR header with 0 bandwidth request. When BS receives the BR header, the Seamless HO procedure completes successfully.

6.3.21.3 Macro diversity handover (MDHO) and fast BS switching

In addition to the HO procedures previously discussed, there are two optional HO modes, MDHO and FBSS. The MDHO or FBSS capability can be enabled or disabled in the REG-REQ/RSP message exchange. With MDHO or FBSS enabled, the MS shall perform the following stages:

— **MDHO Decision**: A MDHO begins with a decision for an MS to transmit to and receive from multiple BSs at the same time. A MDHO can start with either MOB_MSHO-REQ or MOB_BSHO-REQ messages.

— **FBSS HO Decision**: A FBSS HO begins with a decision for an MS to receive/transmit data from/to the anchor BS that may change within the diversity set. A FBSS HO can be triggered by either MOB_MSHO-REQ or MOB_BSHO-REQ messages.

— **Diversity Set Selection/Update**: An MS may scan the neighbor BS and select BSs that are suitable to be included in the diversity set. The MS shall report the selected BSs and the diversity set update procedure shall be performed by the BS and the MS.

— **Anchor BS Selection/Update**: An MS is required to continuously monitor the signal strength of the BSs that are included in the diversity set. The MS shall select one BS from its current diversity set to be the anchor BS and reports the selected anchor BS on CQICH or MOB_MSHO-REQ message.

If MOB_BSHO-RSP specifies another HO type value than requested by MOB_MSHO-REQ (for example, the MS requested HO and the BS prescribes MDHO/FBSS), then the MS should perform the procedure specified by the BS.

The MS should perform the procedure specified by the BS in HO Type field of MOB_BSHO-REQ.

When a diversity set and an anchor BS are maintained at the MS and the BS, the BS can decide to put the MS MDHO on a per burst allocation basis, based on factors such as QoS of a particular service flow being transmitted.

6.3.21.3.1 MDHO decision and initiation

Support of MDHO is optional for both the MS and the BS.
For an MS and a BS that support MDHO, the MS and the BS shall maintain a list of BSs that are involved in MDHO with the MS. The list is called the diversity set. Among the BSs in the diversity set, an anchor BS is defined. Regular operation when MS is registered at a single BS is a particular case of MDHO with diversity set consisting of single BS, which in this case shall be the anchor BS. When operating in MDHO, the MS communicates with all BSs in the diversity set for UL and DL unicast messages and traffic.

There are two methods for the MS to monitor DL control information (i.e., DL-MAP, UL-MAP, and FCH) and DL broadcast messages. The first method is the MS monitors only the anchor BS for DL control information and DL broadcast messages. In this case, the DL-MAP and UL-MAP of the anchor BS may contain burst allocation information for the nonanchor active BS. The second method is the MS monitors all the BSs in the diversity set for DL control information and DL broadcast messages. In this case, the DL-MAP and UL-MAP of any active BS may contain burst allocation information for the other active BSs. The method to be used by MS is defined during the REG-REQ and REG-RSP handshake.

A MDHO begins with a decision for an MS to transmit/receive unicast messages and traffic from multiple BSs at the same time interval. For DL MDHO, two or more BSs provide synchronized transmission of MS DL data so that diversity combining can be performed by the MS. For UL MDHO, the transmission from an MS is received by multiple BSs so that selection diversity of the information received by multiple BSs can be performed.

The BS supporting MDHO shall broadcast the DCD message that includes the H_Add Threshold and H_Delete Threshold. These thresholds are used by the MDHO capable MS to determine if MOB_MSHO-REQ should be sent. When long-term CINR of a active BS in the current diversity set is less than H_Delete Threshold, the MS shall send MOB_MSHO-REQ to requires dropping this active BS from the diversity set; when long-term CINR of a neighbor BS is higher than H_Add Threshold, the MS shall send MOB_MSHO-REQ to require adding this neighbor BS to the diversity set.

The decision to update the diversity set begins with a notification by the MS through the MOB_MSHO-REQ message or by the BS through the MOB_BSHO-REQ management message. The process of anchor BS update may begin with MOB_MSHO-REQ from MS or MOB_BSHO-REQ from the anchor BS. Acknowledgement with MOB_BSHO-RSP of a notification is required. After MS transmits MOB_MSHO-REQ, MS shall not transmit any MOB_MSHO-REQ prior to expiration of timer MS_handover_retransmission_timer. MS shall deactivate timer MS_handover_retransmission_timer on MS transmission of MOB_HO-IND or MS receipt of MOB_BSHO-RSP. Process of anchor BS update may also begin with anchor switching indication via fast-feedback channel.

If an MS that transmitted a MOB_MSHO-REQ message detects an incoming MOB_BSHO-REQ message, it shall ignore that MOB_BSHO-REQ message. A BS that transmitted a MOB_BSHO-REQ message and detects an incoming MOB_MSHO-REQ or MOB_HO-IND message from the same MS shall ignore its own previous request.

The BSs involving in MDHO with an MS shall use the same set of CIDs for the connections that are established with the MS. The BS may assign a new set of CIDs to the MS during diversity set update through MOB_BSHO-REQ message and MOB_BSHO-RSP message.

There are several conditions that are required to enable macro diversity handover between MS and a group of BSs. These conditions are listed as follows:

- The BSs involving in MDHO are synchronized based on a common time source.
- The frames sent by the BSs involving in MDHO at a given frame time arrive at the MS within the prefix interval.
- BSs involving in MDHO have synchronized frame structure.
- BSs involving in MDHO have the same frequency assignment.
— BSs involving in MDHO shall use the same set of CID(s) for the connections that are established with the MS.
— The same MAC/PHY PDUs shall be sent by all the BSs involving in MDHO to the MS.
— BSs involved in MDHO are also required to share or transfer MAC context. Such context includes all information the MS and BS normally exchange during Network Entry, particularly authentication state, so that an MS authenticated/registered with one of BSs from diversity set BSs is automatically authenticated/registered with other BSs from the same diversity set. The context also includes a set of service flows and corresponding mapping to connections associated with MS, current authentication, and encryption keys associated with the connections.

### 6.3.21.3.2 FBSS decision and initiation

Support of FBSS is optional for both MS and BS.

For MS and BS that support FBSS, the MS and the BS shall maintain a list of BSs that are involved in FBSS with the MS. The list is called the diversity set. Among the BSs in the diversity set, an anchor BS is defined. Regular operation when MS is registered at a single BS is a particular case of FBSS with diversity set consisting of single BS, which in this case shall be the anchor BS. When operating in FBSS, the MS only communicates with the anchor BS for UL and DL messages including management and traffic connections. Transition from one anchor BS to another (“switching”) is performed without invocation of HO procedure described in 6.3.21.2. Anchor update procedure is defined in 6.3.21.3.4.

The BS supporting FBSS shall broadcast the DCD message that includes the H_Add Threshold and H_Delete Threshold. These thresholds may be used by the FBSS capable MS to determine if MOB_MSHO-REQ should be sent to request changing Diversity Set. When mean CINR of an active BS in the current diversity set is less than H_Delete Threshold, the MS may send MOB_MSHO-REQ to request dropping this BS from the diversity set; when mean CINR of a neighbor BS is higher than H_Add Threshold, the MS may send MOB_MSHO-REQ to request adding this neighbor BS to the diversity set. In each case, Anchor BS responds with MOB_BSHO-RSP with updated Diversity Set.

After the MS completes the initial network entry, re-entry procedure or the handover procedure defined in 6.3.21.2, the BS automatically becomes an Anchor BS. Also, the Diversity Set is initialized and TEMP_BSID of the Anchor BS is set to zero. However, the TEMP_BSID and Diversity Set shall be maintained when Anchor BS switching defined in 6.3.21.3.4 occurs.

The process of Anchor BS update may begin with MOB_MSHO-REQ from MS or MOB_BSHOREQ from the Anchor BS. Acknowledgement of MOB_MSHO-REQ with MOB_BSHO-RSP is required. After MS transmits MOB_MSHO-REQ, MS shall not transmit any MOB_MSHO-REQ prior to expiration of timer MS_handover_retransmission_timer. The MS shall deactivate the timer MS_handover_retransmission_timer upon MS transmit of MOB_HO-IND or upon MS receipt of MOB_BSHO-RSP. The process of Anchor BS update may also begin with Anchor switching indication via fast-feedback channel.

If an MS that transmitted a MOB_MSHO-REQ message detects an incoming MOB_BSHO-REQ message, it shall ignore that MOB_BSHO-REQ message. A BS that transmitted a MOB_BSHO-REQ message and detects an incoming MOB_MSHO-REQ or MOB_HO-IND message from the same MS shall ignore its own previous request.

There are several conditions that are required to enable fast BS switching HO between MS and a group of BSs. These conditions are listed as follows:

— BSs involving in FBSS are synchronized based on a common time source.
— The frames sent by the BSs from diversity set arrive at the MS within the prefix interval.
— BSs involving in FBSS have synchronized frames.
— BSs involving in FBSS operate at same frequency channel.
— BSs involving in FBSS are also required to share or transfer MAC context. Such context includes all information MS and BS normally exchange during Network Entry, particularly authentication state, so that an MS authenticated/registered with one of BSs from diversity set BSs is automatically authenticated/registered with other BSs from the same diversity set. The context also includes a set of service flows and corresponding mapping to connections associated with MS, current authentication, and encryption keys associated with the connections.

6.3.21.3.3 Diversity set update for MDHO/FBSS

When MOB_MSHO-REQ is sent by an MS, the MS may provide a possible list of BSs to be included in the MS’s diversity set. The MS may evaluate the possible list of BSs through the received MOB_NBR-ADV message, and previously performed signal strength measurement, propagation delay measurement, scanning, ranging, and association activity. When MOB_BSHO-RSP is sent by the anchor BS or BSs in the MS’s current diversity set, the BSs may provide a list of BSs recommended for incorporation into the MS’s diversity set.

When MOB_BSHO-REQ is sent by the anchor BS or BSs in the MS’s current diversity set, the BSs may provide a recommended list of BSs to be included in the MS’s diversity set. The criteria for the recommendation may be based on expected QoS performance to MS requirements and list of BSs that can be involved in MDHO/FBSS as broadcast in MOB_NBR-ADV.

MS actual update of diversity set is recommended, but not required. However, the actual diversity set chosen by the MS shall be a subset of those listed in MOB_BSHO-RSP or in MOB_BSHO-REQ and shall be indicated in MOB_HO-IND, with MDHOFBSS_IND_type field in MOB_HO-IND set to 0b00 (Confirm Diversity Set Update). The MS may reject the diversity set recommended by the anchor BS by setting the MDHOFBSS_IND_type field in MOB_HO-IND to 0b10 (Diversity Set Update Reject) and may include an MS preferred target BS to include in the MS’s diversity set. The BS may reconfigure the diversity set list, including MS preferred target BS and retransmit MOB_BSHO-RSP message to the MS.

After an MS or BS has initiated a diversity set update using MOB_MSHO/BSHO-REQ, the MS may cancel the diversity set update at any time. The cancellation shall be made through transmission of a MOB_HO-IND with MDHOFBSS_IND_type field set to 0b01.

If the MS is operating in FBSS, when adding a new BS to the MS’s diversity set, the MS may initiate ranging with newly added BS.

6.3.21.3.4 Anchor BS update for MDHO/FBSS

There are two mechanisms for the MS and BS to perform anchor BS update. The first mechanism is by using the HO messages. The second mechanism is by using the fast anchor BS selection feedback. The preferred anchor BSs shall be within the current diversity set of the MS. The MS may select the preferred anchor BS through the previously performed signal strength measurement. The BS decides the target anchor BS based on the MS report. MS and BS supporting MDHO or FBSS shall implement one of the two mechanisms to perform anchor BS update.

6.3.21.3.4.1 HO MAC management message method

For the method using MAC management message, the MS reports the preferred anchor BS by using the MOB_MSHO-REQ message. The BS informs the MS of the anchor BS update through MOB_BSHO-REQ or MOB_BSHO-RSP message with the estimated switching time. The MS shall update its anchor BS based on the information received in MOB_BSHO-REQ or MOB_BSHO-RSP. The MS also shall indicate its acceptance of the new anchor BS through MOB_HO-IND, with MDHOFBSS_IND_type field set to 0b00. The MS may reject the anchor BS update instruction by the BS, by setting the MDHOFBSS_IND_type field
in MOB_HO-IND to 0b10 (Anchor BS Update Reject) and may propose an alternate Anchor BS. The BS may reconfigure the anchor BS list and retransmit MOB_BSHO-RSP or MOB_BSHO-REQ message to the MS. After an MS or BS has initiated an anchor BS update using MOB_MSHO/BSHO-REQ, the MS may cancel anchor BS update at any time. The cancellation shall be made through transmission of a MOB_HO-IND with MDHOFBSS_IND_type field set to 0b01.

When switching to a new anchor BS within the MS’s diversity set, the network entry procedures, as depicted in Figure 144, are not required and shall not be performed by the MS.

### 6.3.21.3.4.2 Fast anchor BS selection feedback mechanism

For MS and BS using the fast-feedback method to update Anchor BS, when the MS has more than one BS in its diversity set, the MS shall transmit fast anchor BS selection information to the current anchor BS using fast-feedback channel. If the MS needs to transmit anchor BS selection information, it transmits the codeword corresponding to the selected anchor BS via its fast-feedback channel. The codeword is identified by TEMP_BSID assigned to the BSs in a diversity set.

Fast-feedback channel shall be allocated by one of the following three methods:

a) Preallocated by MOB_BSHO-RSP or MOB_BSHO-REQ when a BS is added to the diversity set.
b) Allocated through Anchor_BS_switch_IE during anchor switching operation.
c) Allocated by UL-MAP of the new anchor BS after the switching period.

For FBSS operation, the time axis is slotted by an ASR (anchor switch reporting) slot that is M frame long. If the current frame number is N, then the ASR slot number shall be the integer quotient of N divided by M. The ASR slot shall start at the frame where frame number modulus M equals to zero. M shall be configured by the DCD. A switching period is introduced whose duration is equals to L ASR slots. L shall be configured by the DCD to be long enough so that certain processes (e.g., HARQ transmission, backhaul context transfer) can be completed at the current anchor BS before the MS switches to the new anchor BS.

The switching operation for L = 2 is illustrated in Figure 151. In the first ASR slot, the MS detects that the signal strength from a BS in the diversity set (e.g., BS B) is better than that of the current anchor BS (e.g., BS A) so that a switch to the new anchor BS is desired. The MS transmits the anchor BS switch indicator at the beginning of the next ASR slot. At the start of the second ASR slot, the MS shall start a switching timer with value equals to the switching period. Starting from the second ASR slot and for the subsequent ASR slots prior to the expiry of the switching timer, the MS shall transmit the anchor switch indicator through CQICH allocated by the current anchor BS (e.g., BS A).

![Figure 151—Fast anchor BS selection mechanism](image)
The current anchor BS may send the Anchor_BS_switch_IE prior to the expiry of the switching timer to do one of the following:

- Acknowledge the MS’s switch indication and/or assign a CQICH at the new anchor BS (BS B), and/or specify a new action time when the switch shall occur, and/or specify a new anchor BS to which to switch.
- Cancel the MS switching event.

If the MS does not receive an Anchor BS Switch IE prior to the expiry of the switching timer, the MS shall switch to the new anchor BS after the expiry of the switching timer. If the MS receives an Anchor BS Switch IE prior to the expiry of the switching timer with no cancellation and no new action time specified, the MS shall switch to the new anchor BS after the expiry of the switching timer. If the MS receives an Anchor BS Switch IE prior to the expiry of the switching timer with new action time specified, the MS shall switch to the new anchor BS at the action time specified. If the MS receives an Anchor BS Switch IE with cancellation prior to the expiry of the switching timer, the MS shall cancel the switching operation. If the MS successfully decodes an Anchor BS Switch IE, the MS shall acknowledge the reception of the IE using the allocated codeword over the CQICH.

Prior to the expiry of the switching timer, the MS shall report CQI of the current anchor BS (e.g., BS A) and anchor switch indication on alternate CQICH opportunities. The timing of the transmission for anchor switch indicator shall refer to the beginning of the switching period, and the anchor switch indicator shall be transmitted at the first CQICH opportunity. For example, the MS shall transmit the indicator at the frames of first and third CQICH opportunities within the switching period if the switching period has four CQICH opportunities indicated by CQICH_allocation_IE. If the MS started the switching operation by indicating a BS within the diversity set (e.g., BS B) as the new anchor BS, the MS shall not indicate another new anchor BS prior to the expiry of the switching timer. Prior to the expiry of the switching timer, if the MS has intention to cancel the switching due to factors such as the signal strength of the new anchor BS (e.g., BS B) is no longer higher than that of the current anchor BS (e.g., BS A) by a certain threshold, the MS shall continue to indicate BS B in the CQICH during the switching period. However, the MS can initiate the cancellation of the anchor BS switch if, and only if, no Anchor_BS_Switch_IE with cancellation flag disabled is received prior to the expiry of the switching timer. In such case, after the expiry of the switching timer, the MS shall stay with BS A and shall transmit the CQI on the same CQICH allocated by BS A in the same fashion as prior to the switch operation starts. On the BS side, after the expiry of the switching timer, the BS A shall continue to monitor the same CQICH allocated to the MS for an implementation dependent duration. If CQI transmission is detected, the BS A shall assume that the MS has cancelled the switch. The MS shall not initiate cancellation of the switch if Anchor_BS_Switch_IE with cancellation flag disabled is received prior to the expiry of the switching timer.

If no cancellation occurs, after the expiry of the switching timer, the MS shall switch to the new anchor BS (e.g., BS B) and monitor the DL of BS B. If the BS B has already preallocated a CQICH to the MS (this can be done using MOB_BSHO-RSP or Anchor Switch IE), the MS reports the CQI using the allocated CQICH and may begin the normal communication with the new anchor BS (e.g., BS B) starting from the first frame after the expiry of the switching timer. If CQICH is not preallocated to the MS prior to the switch, the MS shall monitor the MAP from the new anchor BS (e.g., BS B) and wait for the CQICH allocation after the switch. If after the switch, the MS does not receive a CQICH allocation, the MS requests the new anchor BS (e.g., BS B) to allocate CQICH channel by transmitting CQICH allocation request header. If the new anchor BS (e.g., BS B) receives CQICH allocation request header, the BS shall allocate a CQICH for the MS.

If MDHO support is negotiated, the BS may assign UL resource to the MS to send combined CQI of active BSs using the feedback header. The BS may also assign fast-feedback channel or enhanced fast-feedback channel for CQI feedback. When such a channel is assigned, the MS shall report the CQI of the anchor BS on the channel.
6.3.21.3.5 MS-assisted coordination of DL transmission at new anchor BS

The following procedure shall only be supported for FBSS.

Once the MS has successfully switched to the new anchor BS, to maintain continuity of transmission to the MS between the old and new anchor BSs, the last successfully received information unit needs to be identified to the new anchor BS. Depending on whether the connection is ARQ-enabled or ARQ-disabled, the identity of the next information unit can be given by the ARQ block sequence number or the MAC SDU sequence number respectively.

MS can optionally support the feedback of ARQ block sequence number or the virtual MAC SDU sequence number after the MS has successfully switched to the new anchor BS. The capability and the support for each connection are defined in the REG-REQ/RSP and DSA-REQ/RSP TLVs respectively.

For the connections that have SN feedback enabled, the following procedures shall be performed by the BS and the MS:

— For ARQ-disabled with SN feedback enabled, the BS shall include a SDU SN extended subheader at least once every $2^p$ MAC PDUs, where $p$ is specified in the MAC header and extended subheader support TLV (11.7.21). Upon receiving anchor BS switching request from the MS, the old anchor BS shall include SDU SN extended subheader in MAC PDU at least once before the expiration of the switching timer. The MS shall maintain MAC SDU sequence number based on the information received from the BS. When the MS receives a MAC PDU without SDU SN extended subheader, the MS shall increment the MAC SDU sequence number by one for every SDU received. When the MS receives MAC SDU sequence number from the BS, it shall reset the MAC SDU sequence number based on the value included in SDU SN extended subheader.

— At the expiration of the anchor switch timer, the new anchor BS should assign UL resource through UL-MAP IE for the MS to transmit the sequence number(s) of ARQ block or virtual MAC SDU on the SN report MAC header (6.3.2.1.6). At the expiration of the anchor switch timer, the MS shall send SN report MAC headers (as described in 6.3.2.1.2.1.7) that include the next ARQ Block (or virtual MAC SDU) sequence number that it is expecting for each of its connections that have SN feedback enabled. The new anchor BS may send the SN request extended subheader to explicitly request an MS to send additional SN report header. After receiving the SN request extended subheader, the MS shall send the requested SN report header. The new anchor BS may assign UL resource through UL-MAP IE for the MS to send the additional SN report header.

— Once the HO to the new anchor BS has been completed, acknowledgement and/or retransmission of any outstanding ARQ blocks is handled per the ARQ mechanism defined in 6.3.4.

6.3.22 Multicast and broadcast service (MBS)

Multicast and Broadcast Services provides an efficient method for concurrent transport of data common to a group of users, using a common multicast CID. MBS service is offered in the downlink only and may be coordinated and optionally synchronized among a group of BS to allow macro-diversity.

The service flows associated with MBS have certain QoS parameters and may require encryption performed using a globally defined sequence of TEKs. Since a multicast connection is associated with a service flow, it is associated with the QoS and traffic parameters for that service flow. All service flows to transmit the same MBS flows, created on any SS, shall have the same service flow management encodings for QoS parameter set (11.13.4).

Service flows to carry MBS data are instantiated on individual SS participating in the service while in Normal Operation. During such instantiation the SS learns the parameters that identify the service and associated service flows. Each BS capable of providing MBS service belongs to a certain MBS Zone,
defined as a set of BS where the same CID and same SA is used for transmitting the content of certain service flow(s). Each MBS Zone is identified by a unique MBS Zone ID.

To ensure proper multicast operation on networks of BS employing MBS, the CIDs used for common MBS content and service shall be the same for all BS within the same MBS-Zone. This allows the SS which has already registered with a service to be seamlessly synchronized with MBS transmissions within an MBS Zone without communicating in the UL or re-registering with other BS within that MBS-Zone. The MBS_Zone ID’s shall not be reused across any two adjacent MBS zones.

ARQ and HARQ are not applicable to multicast connections as there is no feedback from the SS at layer 1 or layer 2. However MBS may be used with time-diversity similar to that used in HARQ transmissions, where some HARQ parameters are used for MBS bursts to allow proper sequencing and time diversity combining when MBS bursts are repeatedly transmitted, but without any layer 1 or layer 2 acknowledgements from the SS.

Logical Channel IDs, which pairs with Multicast CID in the Extended MBS DATA IE, is allocated to each MBS Contents ID value in the order that it is included in the MBS Contents IDs TLV (11.13.35). As a result, an SS can receive multiple MBS messages for an MBS connection with different MBS contents distinguished by Logical Channel ID belonging to a Multicast CID. The BS shall allocate MBS SDUs in the order defined in the Extended MBS DATA IE.

If a DL multicast connection is to be encrypted, each SS participating in the connection shall have an additional security association (SA) allowing that connection to be encrypted using keys that are independent of those used for other encrypted transmissions between the SS and the BS.

Multicast and broadcast service flows may be encrypted at the application layer or MAC or both. Upper layer encryption may be employed to prevent non-authorized access to multicast and broadcast content. MBS may provide access control against theft of service by data encryption based on advanced encryption standard with counter mode encryption (AES-CTR) defined in NIST Special Publication 800-38A and FIPS 197. Details of MBS security are defined in 7.8.3.

For all BSs that belong to the same MBS Zone, the following coordination shall be assured:

— The set of MAC SDUs carrying MBS content shall be identical in the same frame in all BS in the same MBS zone;
— The mapping of MAC SDUs carrying MBS content onto MAC PDUs shall be identical in the same frame in all BS in the same MBS Zone, meaning, in particular, identical SDU fragments and identical fragment sequence number (block sequence number) and fragment size

Coordination in the MBS Zone assures that the SS may continue to receive MBS transmissions from any BS that is part of the MBS Zone, regardless of the SS operating mode—Normal Operation, Idle Mode—without need for the SS to register to the BS from which it receives the transmission.

In addition to coordination, MBS transmissions may optionally be synchronized across all BS’s within an MBS Zone. This option enables an SS to receive the multicast or broadcast transmission from multiple BS using macrodiversity, and thereby improve the reliability of reception. When macrodiversity is used, the mapping of SDUs into the MBS Bursts is identical, and the same MBS bursts are transmitted at the same time in all involved BS; additional parameters may also be required to be identical across BSs if macrodiversity is used, see 6.3.22.2.

A BS may provide the SS with MBS content locally within its coverage and independently of other BSs. The single BS provision of MBS is therefore a configuration where an MBS Zone is configured to consist of one BS only. This configuration may be provided as one of the possible cases of MBS. In this case, the BS may
use any multicast CID value for providing the MBS service, independently of other BSs, so the SS receives the MBS data from its serving BS, and the SS should not expect the service flow for this MBS connection to continue should the SS leave the serving BS. However, if the MS moves to a BS that is transmitting the same MBS flows in another MBS Zone and updates its Service Flow management encodings (6.3.22.1.1), the MS may continue to receive the same MBS flows.

6.3.22.1 Establishment and maintenance of MBSs

Establishment of MBSs for a specific SS with respect to certain service flow is always performed when the SS is in Normal Operation with a serving BS. MBSs are associated with multicast and broadcast service flows. Multicast and broadcast service flows are not dedicated to the specific SS and are maintained even though the SS is either in awake/sleep mode or in the idle mode. When an SS is registered at a BS for receiving MBS, multicast and broadcast service flows shall be instantiated as multicast connections. Data of multicast and broadcast service flows may be transmitted from BS and received at SS also regardless of what mode the SS is currently in. The BS may establish a DL MBS by creating a multicast and broadcast service flows when the service commences. Mapping of multicast and broadcast SFIDs to CIDs shall be known to all BSs belonging to the same MBS zone. The method of making all BS in the same MBS Zone aware of MBS flows and associated MBS Service Flows—including multicast CID assignment, QoS parameter set, and Classification Rule(s)—is outside the scope of the standard. As the classification and transmission of MBS flows may be supported on a BS in an MBS Zone regardless of the presence or absence of any SS in Normal Operation receiving the service, the BS may retain MBS service flow management encodings sufficient to do classification and scheduling of received MBS flows, even when no SS in Normal Operation receiving the service is registered at the BS.

When the SS registers at the BS for receiving multicast and broadcast services, the BS or SS may initiate the DSA procedure with respect to multicast and broadcast connections. Such knowledge may be used to initiate bidirectional upper layers communication between the SS and the network for the purpose of configuration of multicast/broadcast service. After successful configuration, the SS shall reuse the same configuration when it moves to another BS without re-configuration.

During communication to the BS the SS may learn the MBS_Zone ID. The SS may continue to receive MBS transmissions from any BS that is part of the MBS Zone, regardless of the SS operating mode—Normal Operation, Idle Mode—without need for update to any service flow management encoding for the MBS flow.

Should the SS transit to a new MBS Zone while in Normal Operation, and provided that SS MBS service flow management encodings have not otherwise been updated using the method provided in 6.3.22.1.1, as part of the handover the BS may include CID_Update in REG-RSP encoding TLV in the RNG-RSP to provide updated service flow management encodings for any affected MBS flow.

When an SS in Idle mode migrates to a BS advertising another MBS Zone, the SS is expected to update the MBS service flow management encodings at that BS to provide for further reception of MBS content. Such an update may include one or more of multicast CIDs, Target SAID parameters, Packet Classification Rule parameters, MBS Zone Identifier Assignment parameter, and MBS Content IDs. If the SS has not received such information from the serving MBS Zone as described in 6.3.22.1.1, the SS may conduct location update to acquire updated MBS service flow management encodings, or may conduct re-entry from Idle mode. The BS may include CID_Update in REG-RSP encoding TLV in the RNG-RSP to provide updated service flow management encodings for any affected MBS flow.

During a Dynamic Service Addition procedure, the BS may include the MBS contents IDs TLV (11.13.35) in the DSA-REQ or DSA-RSP message to establish an MBS service flow for multiple MBS contents. The BS may include MBS Contents Identifier TLV in DSA-REQ/RSP to establish an MBS connection with multiple MBS contents.
The SS shall not include the MBS_Zone ID or MBS contents IDs in a DSA-REQ message.

6.3.22.1.1 Inter-MBS Zone transition

To allow seamless transition from one MBS Zone to another without any interruption of MBS data service and operation, the MS should update MBS service flow management encodings including multicast CID, Target SAID parameter, Packet Classification Rule parameter(s), MBS Zone Identifier Assignment parameter, and MBS contents IDs. If the SS has no MCID information regarding the new MBS Zone, then the SS is required to acquire MCID context through the other procedures, e.g., location-update, handover, or network-entry.

If the SS has an indication that the MCID has no continuity in the target MBS zone then the SS shall delete the MCID and MBS Zone Identifier Assignment related to the MCID.

6.3.22.2 Performance enhancement with macro diversity

Multiple BS’s participating in the same multi-BS-MBS service MAY be time and frequency synchronized in the transmissions of common MBS data to allow macro diversity gain at the SS. When macro-diversity is enabled the MBS bursts positions and dimensions as well as PHY parameters shall be the same across all BS’s within the same MBS Zone. In addition to the coordination parameters identified in 6.3.22.1, macro-diversity synchronization requires that all BS’s within the same MBS Zone shall use the same

- DUIC parameters associated with each MBS Burst including FEC Type, Modulation Type, and Repetition Coding
- Mapping of SDUs to PDU (order of the SDUs and fragments) including Sub Headers
- Mapping of PDUs to bursts
- Order of bursts in the zone/region
- MAP construction

The way that multiple BSs accomplish the synchronized transmission (which implies performing functions like classification, fragmentation, scheduling at a centralized point called the MBS Server) is outside the scope of the standard.

6.3.22.3 Power saving operation

To facilitate power efficient reception of MBS data, an MBS MAP IE may be placed in the DL-MAP to point to the location of a dedicated MBS region allocation in the DL subframe. The purpose of this IE is to do the initial direction of the SS to the MBS allocation, and to redirect any SS that has lost synchronization with MBS allocations back to the next MBS allocation.

6.3.22.4 Multicast and broadcast zone (MBS_Zone)

Different CID s or different SAs may be used in different service areas for the same multicast and broadcast service flow. A multicast and broadcast zone identifier (MBS_ZONE_ID) is used to indicate a service area through which a CID and SA for a broadcast and multicast service flow are valid. A BS that supports Multi-BS Access MBS shall include the MBS zone identifier(s) as a MBS zone identifier list in the DCD message (see Table 575). The MBS zone identifier shall not be '0'.

When the MBS zone identifier list appears in DCD settings TLV in MOB_NBR-ADV message with only one value of '0', then the neighbor BS is not affiliated with any MBS zone. An MBS zone that is adjacent to another MBS zone is a neighbor MBS zone to that MBS zone.
In case BS sends DSA for establishment of connection for MBS, MBS_ZONE shall be encoded in the DSA message (see 11.13.27). If an SS in idle mode moves into BSs in the same MBS zone, the SS does not have to re-enter the network to re-establish a connection or a connection defined by MBS Contents Identifier to monitor the multicast and broadcast service flow. However, if an SS moves into a different MBS zone, the SS may need to update service flow management encodings for the multicast and broadcast service flow. One BS may have multiple MBS zone IDs for different MBS services.

6.3.23 MS idle mode (optional)

Idle mode is intended as a mechanism to allow the MS to become periodically available for DL broadcast traffic messaging without registration at a specific BS as the MS traverses an air link environment populated by multiple BSs, typically over a large geographic area. Idle mode benefits MS by removing the active requirement for HO, and all normal operation requirements. By restricting MS activity to scanning at discrete intervals, idle mode allows the MS to conserve power and operational resources.

Idle mode benefits the network and BS by providing a simple and timely method for alerting the MS to pending DL traffic directed toward the MS, and by eliminating air interface and network HO traffic from essentially inactive MS.

The BSs are divided into logical groups called paging groups. The purpose of these groups is to offer a contiguous coverage region in which the MS does not need to transmit in the UL, yet can be paged in the DL if there is traffic targeted at it. The paging groups should be large enough so that most MSs will remain within the same paging group most of the time and small enough so that the paging overhead is reasonable. Figure 152 shows an example of four paging groups defined over multiple BS arranged in a hexagonal grid. A BS may be a member of one or more Paging Groups comprised of differing groupings of BS, of varying cycles and offsets, providing support for not only the geographic requirements of Idle Mode operation but may also support differentiated and dynamic quality of service requirements and scalable load-balancing distribution.

![Figure 152—Paging groups example](image)

The paging-groups are defined in the management system.
Idle comprises the following activities/stages:

- MS idle mode initiation
- Cell selection
- MS Broadcast Paging message time synchronization
- MS paging unavailable interval
- MS paging listening interval
- BS paging interval
- BS Broadcast Paging message
- Paging availability mode termination

### 6.3.23.1 MS idle mode initiation

Idle mode initiation may begin after MS deregistration. During normal operation with its serving BS, an MS may signal intent to begin idle mode by sending a DREG-REQ message with the De-registration_Request_Code parameter = 0x01; request for MS deregistration from serving BS and initiation of MS idle mode. When the BS decides to reject MS-initiated idle mode request, the BS shall send a DREG-CMD with action code 0x06 in response to this DREG-REQ message. The BS may include REQ-Duration TLV in this DREG-CMD message. In this case, the MS may retransmit the DREG-REQ message after the expiration of REQ_Duration. If the MS does not receive the DREG-CMD message within T45 timer expiry after it sends the DREG-REQ message to the BS, the MS shall retransmit the DREG-REQ message as long as DREG Request Retry Count has not been exhausted. Otherwise, the MS shall reinitialize MAC. Also, the BS shall start Management_Resource_Holding_Timer to maintain connection information with the MS as soon as it sends the DREG-CMD message to the MS. If Management_Resource_Holding_Timer has been expired, the BS shall release connection information with the MS.

Similarly, a serving BS may signal for an MS to begin idle mode by sending a DREG-CMD message with action code 0x05 in unsolicited manner. This unsolicited DREG-CMD may include the REQ-Duration TLV. When an MS receives an unsolicited DREG-CMD without the REQ_Duration TLV, the MS shall immediately send a DREG-REQ message. In this case of BS-initiated idle mode, the serving BS shall start the T46 timer as well as Management_Resource_Holding_Timer at the same time. If the BS does not receive the DREG-REQ message with the De-registration_Request_Code parameter = 0x02 from the MS in response to the unsolicited DREG-CMD message with action code 0x05 within T46 timer expiry, the BS shall retransmit the DREG-CMD message with action code 0x05 in unsolicited manner as long as DREG command retry count has not been exhausted. MS shall enter idle mode after it sends DREG-REQ message with the De-Registration_Request Parameter = 0x02 in response to the unsolicited DREG-CMD message with action code 0x05.

As another case of BS initiated Idle Mode, the serving BS may also include a REQ-duration TLV with an Action Code = 0x05 in the DREG-CMD, signaling for an MS to initiate an Idle Mode request through a DREG-REQ with De-Registration_Request Code = 0x01, request for MS De-Registration from serving BS and initiation of MS Idle Mode, at REQ-duration expiration. In this case, BS shall not start T46 timer. MS may include Idle Mode Retain Information TLV with in DREG-REQ message with De-Registration_Request Code = 0x01 transmitted at the REQ-duration expiration. In this case, BS shall transmit another DREG-CMD message with Action Code=0x05 including Idle Mode Retain Information TLV.

MS may reject the unsolicited Idle Mode request from BS when MS has a pending UL data. For this, MS shall send DREG-REQ with De-Registration_Request Code = 0x03 in response to the unsolicited DREG-CMD with an Action Code = 0x05. Upon receiving DREG-REQ with De-Registration_Request Code = 0x03, BS shall stop T46 timer and Management Resource Holding Timer and resume all connection information for MS.
At the expiration of T46 timer due to no reception of DREG-REQ message, BS shall retransmit the unsolicited DREG-CMD message, reset Management_Resource_Holding_Timer, and increment DREG Command Retry Count. These operations may go on until BS receives the DREG-REQ message from MS. If DREG Command Retry Count is exhausted, BS shall does not retransmit DREG-CMD message any more. On the contrary, if BS receives DREG-REQ message with the De-Registration_Request_Code parameter = 0x02 as long as DREG Command Retry Count is not exhausted, BS regards MS as entering idle mode normally and deletes the MS’s connection information at expiration of management resource holding timer.

For MS terminating normal operation with the serving BS and entering idle mode, the paging controller, i.e., the serving BS or other network entity administering idle mode activity for the MS, may retain certain MS service and operational information useful for expediting a future MS network reentry from idle mode. The MS may request the paging controller (refer to subclause 11.1.8.2) to retain specific MS service and operational information for idle mode management purposes through inclusion of the Idle Mode Retain Information element in the DREG-REQ management message. While retained MS service and operational information may include service flow management encodings definitions as per 6.3.14 and 11.13, retained information shall not include service flow CID values of unicast transport CIDs. Retained information shall include service flow CID values of Multicast CIDs for multi-BS-MBS flows. Retained information shall not include management CIDs. The serving BS shall report the likely effect on expedited future MS network reentry due to paging controller retention of MS service and operational context by reporting the indicative Idle Mode Retain Information element in a DREG-CMD message. Similarly, the BS may also include Idle Mode Retain Information element in the unsolicited DREG-CMD message.

The MS shall maintain an idle mode timer and paging controller shall maintain an idle mode system timer to provide an interval timer to prompt MS idle mode location update activity and demonstrate MS continued network presence to revalidate paging controller retention of MS service and operational information. Idle mode timer and idle mode system timer shall start on serving BS transmission of DREG-CMD message directing MS transition to idle mode. Idle mode timer and idle mode system timer shall recycle on any successful MS network idle mode location update. On expiration of idle mode system timer or on MS network entry/reentry and resumption of normal operation, the paging controller shall discard all MS service and operational information retained for idle mode management purposes. On expiration of idle mode timer, the MS shall consider that paging controller has discarded all MS service and operational information retained for idle mode management purposes. If the MS intends to retain the MS service and operational information, the MS should avoid idle mode timer and idle mode system timer expiration, by performing location update operation sufficiently ahead of the time expiration of the idle mode timer and idle mode system timer.

When MS enters idle mode, ARQ state information and parameters between MS and BS are removed and ARQ is reset when connection is setup during network reentry after idle mode.

The MS may request BS inclusion of MS MAC address hash in MOB_PAG-ADV message at regular intervals, regardless of need for notification, by including the MAC Hash Skip Threshold TLV (11.1.8.1) in a DREG-REQ message with action code 0x01. The value of MAC Hash Skip Threshold TLV specifies the maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC address hash of an MS for which the action code is 00 (No Action Required). Provided the BS approves the MS deregistration with initiation of idle mode and elects the MAC Hash Skip Threshold function, the BS shall respond by sending DREG-CMD message with action code 0x05 and including the MAC Hash Skip Threshold TLV.

### 6.3.23.2 Cell selection

At MS idle mode initiation, an MS may engage in cell selection to obtain a new preferred BS. A preferred BS is a BS that the MS evaluates and selects as the BS with the best air interface DL properties, which may
include the RSSI, CINR, cell type and the available radio resources, etc. The preferred BS may be the MS’s previous serving BS. In all other respects, cell selection is similar to 6.3.21.2.1.

6.3.23.3 MS Broadcast Paging message time synchronization

At evaluation and selection of the preferred BS, the MS shall synchronize and decode the DCD and DL-MAP for the preferred BS, extracting the frame size and frame number. The MS shall evaluate the frame size and frame number and use them to determine time until next regular BS paging interval for the preferred BS. The calculated time until the next regular BS paging interval, less any MS DL scanning, decoding, and synchronization time requirements, shall be the MS paging unavailable interval.

6.3.23.4 MS paging unavailable interval

During MS paging unavailable interval, the MS may power down, scan neighbor BSs, reselect a preferred BS, conduct ranging, or perform other activities for which the MS will not guarantee availability to any BS for DL traffic. Should the MS reselect a preferred BS during the MS paging unavailable interval, then the MS shall return to the MS Broadcast Paging message time synchronization stage.

6.3.23.5 MS paging listening interval

The MS shall scan, decode the DCD and DL-MAP, and synchronize on the DL for the preferred BS in time for the MS to begin decoding any BS Broadcast Paging message during the entire BS paging interval. At the end of MS paging listening interval, providing that the MS does not elect to terminate the MS idle mode, the MS may return to MS paging unavailable interval.

If the BS transmits the Broadcast Control Pointer IE, the MS shall read and react to this message as follows:

a) If the DCD Count in DL MAP and/or UCD Count in UL MAP is different from Configuration Change Count of which DCD and/or UCD MS retains, even if scheduled to be in a paging unavailable interval the MS shall awaken at DCD_UCD Transmission Frame in time to synchronize to the DL and decode the DCD and UCD message in the frame, if present. If the MS fails to decode one or both of DCD and UCD, or no DCD or UCD was transmitted by the BS, the MS shall continue decoding all subsequent frames until it has acquired both updated DCD and UCD. Upon successful completion of DCD and UCD decoding, the MS shall immediately return to regular Idle Mode operation.

b) If Skip Broadcast_System_Update is set to 0, even if scheduled to be in a paging unavailable interval, the MS shall awaken at Broadcast_System_Update_Transmission_Frame in time to synchronize to the DL and decode the DL-MAP and any message, if present. Upon completion, the MS shall immediately return to regular idle mode operation.

A BS paging interval shall occur during the N frames beginning with the frame whose frame number, \( N_{frame} \), meets the condition

\[ N_{frame} \mod PAGING_CYCLE == PAGING_OFFSET \]

on each BS, where N is Paging Interval Length. A BS shall broadcast at least one, but may broadcast more than one BS Broadcast Paging messages during the MS Paging Listening Interval. Different BSs may synchronize their MS Paging Listening Intervals.

6.3.23.6 BS Broadcast Paging message

A BS Broadcast Paging message is an MS notification message indicating either the presence of DL traffic pending, through the BS or some network entity, for the specified MS or to poll the MS and request a location update without requiring a full network entry. The BS Broadcast Paging message shall be sent on
the Broadcast CID or Idle Mode Multicast CID (defined in Table 558 in 10.4) during the BS paging interval. A Broadcast Paging message shall be transmitted during the MS Paging Listening Interval in order to advertise the BS supported Paging Groups, regardless of any requirement for notification of an MS, and even without notification of any MS.

The BS Broadcast Paging message shall include one or more Paging Group IDs identifying the logical affiliations of the transmitting BS.

MSs are identified in the BS Broadcast Paging message by their MS MAC address hash. A single BS Broadcast Paging message may include multiple MAC Addresses. For a given BS Broadcast Paging message in a specific BS pacing interval, the BS shall include only those MS MAC address hash particular to the Paging Interval Length, frame number, PAGING_CYCLE, and PAGING_OFFSET (see 6.3.23.5).

The BS Broadcast Paging message shall also include an action code directing each MS notified via the inclusion of its MS MAC address hash as appropriate:

- 0b00: No action required
- 0b01: Perform ranging to establish location and acknowledge message
- 0b10: Perform initial network entry
- 0b11: Reserved

When MAC Hash Skip Threshold (11.1.8.1) set to 0xFF is included in DREG-CMD message at MS idle mode initiation, MAC Address Hash of an MS shall be omitted in every MOB_PAG-ADV message for which the MS need not be paged, and as would result in MOB_PAG-ADV notification of the MS with action code 0b00 (No Action Required). MS shall maintain an MS MAC Hash Skip Counter and BS shall independently maintain a BS MAC Hash Skip Counter for count of successive MOB_PAG-ADV messages that omit individual MS MAC address hash and any action code. BS shall maintain one such respective BS MAC Hash Skip Counter for each MS idle mode initiation and for which BS is currently serving as preferred BS. MS and BS shall reset their respective MAC Hash Skip Counter when BS transmits MOB_PAG-ADV including MS MAC address hash and action code.

After transmitting the Broadcast Paging message with action code 0b01 (Perform Ranging) or 0b10 (Enter Network), if the BS does not receive RNG-REQ from the MS paged until the next MS paging listening interval, the BS shall retransmit the Broadcast Paging message. Every time the BS retransmits the Broadcast Paging message, it decreases the predefined Paging Retry Count by one. If the BS does not receive RNG-REQ from the MS until the Paging Retry Count decreases to zero, the BS determines that the MS is unavailable, and shall send a message over the backbone network to indicate that the list of MSs in idle mode shall be updated in all BSs that belong to the same paging group.

For a BS Broadcast Paging message to be transmitted to indicate the presence of DL traffic pending, there shall be at least a packet in the DL traffic whose Paging Preference indicates paging generation.

### 6.3.23.7 Paging availability mode termination

Idle mode may only be terminated through

- MS reentry to the network
- Paging controller detection of MS unavailability through repeated, unanswered paging messages
- Expiration of the idle mode system timer

### 6.3.23.7.1 MS side

An MS may terminate MS idle mode at any time.
An MS shall terminate idle mode and reenter the network if it decodes a BS Broadcast Paging message that contains the MS own MS MAC address hash and action code 0b10 (Enter Network). In the event that an MS decodes a BS Broadcast Paging message that contains the MS own MS MAC address hash and action code 0b01 (Perform Ranging), the MS shall conduct and complete idle mode location update to establish location to the network and acknowledge message decoding. In both cases for the OFDMA PHY, if a PHY-specific ranging code and transmission opportunity is assigned to the MS in the MOB_PAG-ADV message, the MS shall perform network reentry or idle mode location update by transmitting the code at the transmission opportunity assigned in the MOB_PAG-ADV message on the dedicated ranging region assigned in the UL-MAP IE (UIUC = 12 and dedicated ranging indicator bit set to 1).

The procedure for PHY-specific ranging code operation is described as follows:

- After receiving the MOB_PAG-ADV and within the Page-Response window, the MS shall transmit the assigned ranging code at the transmission opportunity in the frames where dedicated ranging regions are assigned in the UL-MAP IE (UIUC = 12 and dedicated ranging indicator bit set to 1). The assigned ranging code transmission can be terminated early if the MS receives a RNG-RSP message with Success status before the end of the Page-Response window.
- In the case where RNG-RSP message with Continue status is received and within the Page-Response window, the MS shall transmit the assigned ranging code at the transmission opportunity in the next frame where the dedicated ranging region is assigned.
- In the case where RNG-RSP message with Success status is not received within the Page-Response window, the MS shall continue with the normal initial ranging procedure for network reentry from idle mode (6.3.22.10) or idle mode location update (6.3.23.8.2).
- In the case where no RNG-RSP message is received or no dedicated ranging region is assigned within the Page-Response window to the MS, the MS shall continue with the normal initial ranging procedure for network reentry from idle mode (6.3.23.9) or idle mode location update (6.3.23.8.2).
- In all other cases, the MS shall use normal network reentry or idle mode location update procedure, as described in 6.3.23.8.2

To prevent collisions from multiple MSs trying to wake from idle mode at the same time, the MS shall use random backoff with the Initial_ranging_backoff_start and Initial_ranging_backoff_end described in Table 571.

When the MS decodes a BS Broadcast Paging message that does not include its MAC Address Hash, it means that the MS is not being paged in the current Broadcast Paging event. For all BS Broadcast Paging messages that the MS decodes during the MS Paging Listening Interval, if no message includes the MAC Address Hash of the MS then the MS may enter its next MS Paging Unavailable Interval.

6.3.23.7.2 BS side

The BS at which the MS reentered the network shall inform the appropriate element in the network of the reentry of the MS. The means by which the BS accomplishes this is outside the scope of this standard.

6.3.23.8 Location update

Location update comprises condition evaluation and update processing.

6.3.23.8.1 Location update conditions

An MS in idle mode shall perform a location update process operation if any location update condition is met. There are five location update evaluation conditions: paging group update, timer update, power down update, MAC hash skip threshold update and MBS update. MS may also perform location update process at will. When an MS performs location update, the MS may include Paging Cycle Change (see 11.5) in RNG-REQ to change Paging Cycle. A BS may also change MS’s Paging Cycle by requesting MS to perform
location update via MOB_PAG-ADV with Action code = 0b01 (i.e., Perform ranging to establish location). Whether MS has requested or BS has initiated, the BS shall include appropriate Paging Information (see 11.1.8.3) in RNG-RSP, in response to RNG-REQ message including Paging_Cycle_Change TLV sent by MS during Location Update.

6.3.23.8.1.1 Paging group update

The MS shall perform the Location Update process when the MS detects a change in paging group. The MS shall detect the change of paging group by monitoring the paging group identifiers, Paging Group IDs, which are transmitted by the Preferred BS in the DCD message or MOB_PAG-ADV broadcast message during the MS Paging Listening Interval. If the Paging Group IDs detected do not include the Paging Group to which the MS belongs, the MS shall determine that the paging group has changed.

6.3.23.8.1.2 Timer update

The MS shall periodically perform location update process prior to the expiration of the idle mode timer.

6.3.23.8.1.3 Power down update

The MS shall attempt to complete a location update once as part of its orderly power down procedure. This mechanism enables the paging controller to update the MS’s exact status and to delete all information for the MS and discontinue idle mode paging control for the MS at the time of power down. At the time of successful power down location update, the paging controller shall release all idle mode retaining information related to the MS. In case of failure of power down information update, the paging controller shall perform availability check using location update polling. Unavailability of MS shall be determined and the paging controller shall delete all idle mode retaining information if the MS does not answer for the BS’s location update polling up to “Paging Retry Count.”

6.3.23.8.1.4 MAC hash skip threshold update

The MS shall perform location update process when the MS MAC hash skip counter exceeds the MAC hash skip threshold (11.1.8.1) successively. After successful location update, the BS and MS shall reinitialize their respective MAC hash skip counters.

6.3.23.8.1.5 MBS update

An MS in idle mode with one or more multi-BS MBS service flows shall perform a location update process when the MS detects a change in MBS Zone unless the MS already has the MCID mappings in the target MBS zone. The Service Flow CID encoding of MCID for MBS flows may be updated in a method outside of this standard. The MS shall detect the change of MBS Zone by monitoring the MBS zone identifier list which is transmitted by the Preferred BS in the DCD message. If the MBS zone identifier list detected does not include the MBS zone identifiers for all multi-BS-MBS flows to which the MS belongs, the MS shall determine that the MBS Zone has changed.

6.3.23.8.2 Location update process

If an MS in idle mode determines or elects to update its location, depending on the security association the MS shares with the target BS, the MS shall use one of two processes: secure location update process or unsecure location update process. For purposes of location update process, the target BS shall be the preferred BS.
6.3.23.8.2.1 Secure location update process

If the MS shares a valid security context with the target BS so that the MS may include a valid HMAC/CMAC Tuple in the RNG-REQ, then the MS shall conduct initial ranging with the target BS by sending a RNG-REQ including Ranging Purpose Indication TLV with Bit 1 set to 1, Location Update Request and Paging Controller ID TLVs (11.1.8.2) and HMAC/CMAC Tuple. If location update is used when an idle MS with one or more multi-BS service flows enters a new MBS Zone, then the MS shall also set bit 4 of Ranging Purpose Indication TLV in RNG-REQ to a value of '1'. If the target BS evaluates the HMAC/CMAC Tuple as valid and can supply a corresponding authenticating HMAC/CMAC Tuple, then the target BS shall reply with a RNG-RSP including the Location Update Response TLV and HMAC/CMAC Tuple completing the location update process. If the paging group has changed, then target BS shall include Paging Group ID TLV in the RNG-RSP. If the target BS responds with a successful Location Update Response = 0x00 (Success of Location Update), the target BS shall notify the paging controller via the backbone network of the MS new location information, the MS shall assume the Paging Group ID of the target BS, and the paging controller may send a message over the backbone network to inform the BS at which the MS entered idle mode that the MS has transitioned to a different Paging Group. Upon receiving RNG-REQ with a Ranging Purpose Indication TLV with bit 4 set to a value of '1', the BS shall include CID_Update TLV in RNG-RSP and shall include at least the SFID, Multicast CID, MBS Zone Identifier Assignment parameter, and may include MBS contents IDs, for any multi-BS-MBS service flow for which the MBS Zone has changed. If the target BS evaluates the HMAC/CMAC Tuple as invalid, cannot supply a corresponding authenticating HMAC/CMAC Tuple, or otherwise elects to direct the MS to use unsecure location update, then the target BS shall instruct the MS to start network reentry using the unsecure location update process by inclusion of Location Update Response TLV in RNG-RSP with a value of 0x01 (Failure of Location Update).

6.3.23.8.2.2 Unsecure location update process

If the target BS does not share a current, valid security context with the MS, or if for any reason the BS has elected to instruct the MS to use Unsecure Location Update, the MS shall initiate Network Re-Entry from Idle Mode method (see 6.3.23.9).

6.3.23.9 Network reentry from idle mode

For the network reentry from idle mode method, the MS shall initiate network reentry with the target BS by sending a RNG-REQ including Ranging Purpose Indication TLV with Bit 0 set to 1 and Paging Controller ID TLVs (11.1.8.2).

If the MS shares a valid security context with the target BS so that the MS may include a valid HMAC/CMAC Tuple in the RNG-REQ, then the MS shall conduct initial ranging with the target BS by sending a RNG-REQ including HMAC/CMAC Tuple.

If MS RNG-REQ includes a Ranging Purpose Indication TLV with Bit 0 set to 1 and Paging Controller ID TLVs, and target BS had not previously received MS information over the backbone network, then target BS may make an MS information request of paging controller over the backbone network and paging controller may respond. Regardless of having received MS information from paging controller, target BS may request MS information from another network management entity via the backbone network.

Network reentry proceeds per 6.3.9 except as may be shortened by target BS possession of MS information obtained from paging controller or other network entity over the backbone network.

For the target BS to notify an MS seeking network reentry from idle mode of reentry process management messages that may be omitted during the current reentry attempt due to the availability of MS service and operational context information obtained over the backbone network, the target BS shall place an HO Process Optimization TLV in the RNG-RSP indicating which reentry management messages may be
omitted. The target BS shall not direct the omission of any reentry process management messages that would compromise the security or integrity of normal operation of the communications as established through an unabridged Initial Entry.

If the target BS evaluates a HMAC/CMAC Tuple included in the RNG-REQ as valid and can supply a corresponding authenticating HMAC/CMAC Tuple, then the target BS may reply with a RNG-RSP including the valid HMAC/CMAC Tuple. The target BS shall not indicate through the HO Process Optimization TLV that the PKM-REQ/RSP management messages may be omitted in the current reentry attempt without inclusion of a valid HMAC/CMAC Tuple. If an MS detects an invalid HMAC/CMAC Tuple included as part of a RNG-RSP during network reentry from idle mode, the MS shall discard the RNG-RSP message.

During network reentry from idle mode the BS shall select the security settings to be applied in the MS using HO optimization security bits (bit 1, bit 2) in HO process optimization TLV included in the RNG-RSP. The MS and BS shall follow the rules defined in 6.3.21.2.8.1.6.6 for the target BS and re-entering MS according to the optimization bits.

Regardless of the HO Process Optimization TLV settings, the target BS may elect to use MS service and operational information obtained over the backbone network to build and send unsolicited SBC-RSP and/or REG-RSP management messages to update MS operational information, or to include REG-RSP-specific (11.7) or SBC-RSP-specific (11.8) message items as TLV items in the RNG-RSP. The target BS may ignore only the first corresponding REQ management message received if it sends an unsolicited SBC-RSP or unsolicited REG-RSP message. MS is not required to send the complimentary REQ management message if it receives an unsolicited SBC-RSP or unsolicited REG-RSP management message prior to MS attempt to send the corresponding REQ management message. Target BS reentry unsolicited response management messages may be grouped into the same DL frame transmission and may be grouped into the same DL frame transmission with the RNG-RSP. However, unsolicited SBC-RSP and unsolicited REG-RSP may not be grouped together into the same DL frame transmission when the PKM-REQ/RSP management message process is required.

If MS RNG-REQ includes Ranging Purpose Indication TLV with Bit 0 set to 1 and Paging Controller ID TLVs, and target BS has received a message over the backbone network containing MS information, the target BS may use MS service and operational information obtained over the backbone network to build and send a REG-RSP message or a RNG-RSP message with REG-RSP encodings TLV that includes service flow remapping information in SFID, New_CID, and Connection_Info TLVs.

During network reentry, the target BS may notify the MS, through the Bit 9 MS DL data pending element of the HO Process Optimization TLV item in RNG-RSP, of post-network reentry MS DL data pending. Upon MS successful reentry at target BS, new serving BS, and new serving BS completing reception of any network reentry pending MS DL data retained and forwarded, MS may reestablish IP connectivity and the new serving BS may send a message over the backbone network to request the old serving BS or other network entity to stop forwarding pre-HO pending MS DL data.

Network entry/reentry process completes with establishment of normal operations.

The target BS shall notify the paging controller via the backbone of MS successful network reentry, and the paging controller may send a message over the backbone network to inform the BS at which the MS entered idle mode that the MS has resumed normal operations at the new serving BS.

**6.3.24 MIHF support**

MIHF support is the support of IEEE 802.21 specific features and functions. The IEEE 802.16 entity may send or receive the MOB_MIH-MSG message to or from the peer IEEE 802.16 entity in order to convey MIHF frames carrying the IEEE 802.21 MIH protocol messages.
When MIH query capability during network entry is enabled (refer to 11.4.1 and 11.8.10), PKM messages may be used to exchange MIH frames for MIH queries.

The MS may submit an MIH query by sending a PKM-REQ message with code 31 (MIH Initial Request) containing an MIHF frame encapsulating the query. Upon receiving this message the BS acknowledges the request by sending a PKM-RSP message with code 32 (MIH Acknowledge). This message does not contain the response to the MIH query, but contains a Cycle TLV (11.9.38) that indicates when the response is expected to be ready for delivery to the MS. This message also contains a Query ID, which the MS may use to correlate the query with the response, and the delivery method (unicast or broadcast) that the BS will use.

When a unicast delivery method has been negotiated, then if the BS is ready to transmit the MIH response, the BS shall allocate bandwidth for the MS in the UL-MAP in the MAC frame indicated by the Cycle TLV. Upon receiving this UL allocation, the MS shall transmit at least a Bandwidth request PDU. If the MS has no data to transmit, the BR field of the Bandwidth request PDU shall be set to 0. The BS may use the receipt of the Bandwidth request PDU to assert the continued presence of the MS. If the MS does not send at least a Bandwidth Request PDU, the BS shall abort the network entry procedure for the MS, otherwise it shall send a PKM-RSP message with code 33 (MIH Comeback Response) containing the encapsulated MIH response. The MIH Comeback Response message shall also contain the Query ID previously sent in the MIH Acknowledge message, which the MS may use to correlate the MIH response with the MIH query. When a broadcast delivery method has been negotiated, then if the BS is ready to transmit the MIH response, the BS shall transmit an SII-ADV message containing the MIH response in the MAC frame indicated by the Cycle TLV.

If the BS is not ready to transmit the MIH response at the time indicated by the Cycle TLV, the MS and BS shall wait for another cycle and repeat the procedures specified in the preceding paragraph. The maximum number of times the MS and BS shall perform those procedures is determined by the MIH max cycles system parameter (Table 10.1, Table 554).

6.3.25 Location Based Services

This subclause provides mechanisms to coordinate the collection, generation, and reporting of information used to determine MS location (e.g., RSSI, CINR, Time Difference of Arrival (TDOA), Time of Arrival (TOA), …). Reporting of BS location information is also described.

6.3.25.1 Time Difference of Arrival (TDOA)

TDOA is a location determination scheme that measures the difference of time arrival for packet transmission between a MS and multiple BSs. There are two types of TDOA - Downlink TDOA (D-TDOA) and Uplink TDOA (U-TDOA) based on whether the measurements are performed in the MS and the BS, respectively.

— D-TDOA - MS may report D-TDOA data in the Relative Delay parameter in MOB_SCN-REP message that indicates the delay of DL signals from a neighbor BS relative to the serving BS. MOB_SCN-REP also reports RSSI and CINR of DL signals from neighbor BS that can be used for MS location estimation. During SBC-REQ/RSP based capability negotiation, HO Trigger metric support (see 11.8.6) indicates which trigger metric that the MS supports.

— U-TDOA - As opposed to D-TDOA that is reported each time MS scanning is completed, U-TDOA enables BS to initiate U-TDOA measurement when it is needed. Annex L describes two algorithms to show the U-TDOA measurement through the coordination of MS, serving BS, and one or more neighbor BS for wireless broadband networks: the General U-TDOA Method, for any FRF (Frequency Reuse Factor); and the Special U-TDOA Method, for FRF = 1.
6.3.26 Persistent Scheduling

Persistent Scheduling is a technique used to reduce MAP overhead for connections with periodic traffic pattern and with relatively fixed payload size. To allocate resources persistently, the BS shall transmit the Persistent HARQ DL MAP IE (8.4.5.3.29) for DL allocations and the Persistent HARQ UL MAP IE (8.4.5.4.28) for UL allocations. The persistently allocated resource and the MCS shall be maintained by the BS and MS until the persistent assignment is de-allocated, changed, or an error event occurs. Persistent Scheduling does not include special arrangements for retransmission of data initially transmitted using persistently allocated resources. Resources for retransmissions can be allocated one at a time as needed using either HARQ DL/UL MAP IE or Persistent HARQ DL/UL MAP IE. Persistent scheduling is defined for OFDMA PHY option only.

6.3.26.1 Persistent Region ID

The resources for persistent allocations are relative to the boundary of a HARQ region, which is identified by a Persistent Region ID. The position of a MSs persistent resource shall be determined based on the HARQ region definition and the slot offset, which is assigned in the Persistent HARQ DL MAP IE or the Persistent HARQ UL MAP IE. The slot offset is counted from the lowest numbered OFDMA symbol in the lowest numbered subchannel of HARQ Region. This operation applies to both DL and UL in TDD and H-FDD operation.

6.3.26.1.1 Downlink operation

6.3.26.1.1.1 BS operation

To change the location of a HARQ region associated with a particular Persistent Region ID, the BS transmits the Persistent HARQ DL MAP IE with a new HARQ Region definition (OFDMA Symbol offset, Subchannel offset, Number of OFDMA symbols, Number of subchannels) and sets the Persistent Region ID field of the Persistent HARQ DL MAP IE to the associated Persistent Region ID. The BS should set the allocation period to the same value for all persistent allocations associated with a particular Persistent Region ID.

6.3.26.1.2 MS operation

If the MS receives a persistent HARQ DL MAP IE, which includes its RCID and has the Persistent Flag set to 1, the MS shall store the Persistent Region ID field and the HARQ region definition. The MS shall determine its resource allocation using the slot offset field and the HARQ region definition. Upon receiving a subsequent Persistent HARQ DL MAP IE in a frame corresponding to the period of the persistent allocation, which has the Persistent Region ID field set to the stored Persistent Region ID, the MS shall store the new HARQ region definition and determine its resource allocation using the slot offset field and the new HARQ region definition. If the MS successfully decodes the DL-MAP and there is no Persistent HARQ DL MAP IE containing its assigned Persistent Region ID, then the MS shall use the stored location for the Persistent Region ID for its persistent allocation.

6.3.26.1.2 Uplink operation

6.3.26.1.2.1 BS operation

To change the location of a HARQ region associated with a particular Persistent Region ID, the BS transmits the Persistent HARQ UL MAP IE with a new HARQ Region definition. For uplink operation, the HARQ region is identified by the start of the UL subframe or allocation start indication information (if included). Additionally, the BS sets the Persistent Region ID field of the Persistent HARQ UL MAP IE to the associated Persistent Region ID. The BS should set the allocation period to the same value for all persistent allocations associated with a particular Persistent Region ID.
6.3.26.1.2.2 MS operation

If the MS receives a persistent HARQ UL MAP IE, which includes its RCID and has the Persistent Flag set to 1, the MS shall store the Persistent Region ID and the HARQ region definition. The MS shall determine its resource allocation using the slot offset field and the HARQ region definition. Upon receiving a subsequent Persistent HARQ UL MAP IE in a distance in time which is multiple of the period of the persistent allocation, which has same Persistent Region ID value, the MS shall store the new HARQ region definition and determine its resource allocation using the slot offset field and the new HARQ region definition. If the MS successfully decodes the UL-MAP and there is no Persistent HARQ UL MAP IE containing its assigned Persistent Region ID, then the MS shall use the stored location for the Persistent Region ID for its persistent allocation.

6.3.26.2 Resource shifting

When a persistently allocated resource is de-allocated, a resource hole is created that consists of unused OFDMA slots as illustrated in Figure 153.

![Resource Hole Diagram](image)

There are five persistent allocated subbursts

De-allocation

subburst

MS7 MS2 MS1 MS3 MS5

MS7 MS1 MS3 MS5

Resource hole

Figure 153—Example resource hole

The BS may use resource shifting to mitigate resource holes. For downlink operation, if the Resource Shifting Indicator in the subburst IEs of the Persistent HARQ DL MAP allocation IE is set to ‘1’, the MS shall shift its persistent resource position by the accumulated slots as indicated by de-allocation commands with slot offsets smaller than its own. For uplink operation, if the Resource Shifting Indicator in the subburst IEs of the Persistent HARQ UL MAP allocation IE is set to ‘1’, the MS shall shift its persistent resource position by the accumulated slots as indicated by de-allocation commands with slot offsets smaller than its own. Note that in this case the MS shifts its resource allocation in response to the subburst IE with RCID different from its own. When the Resource Shifting Indicator is set to ‘0’, the MS shall not shift its persistent resource position in response to subburst IEs with RCID different from its own. Figure 154 shows exemplary operation of resource shifting where the resource of MS2 is de-allocated. Since MS1, MS3 and MS5 are located after MS2, their slot offset values are larger than that of MS2. Therefore, their slot position is shifted to remove the resource hole.
6.3.26.3 HARQ retransmission

The BS may use any one of the following IEs to assign resources for HARQ retransmissions:

**Downlink:**
- HARQ DL MAP Allocation IE
- Persistent HARQ DL MAP Allocation IE with Persistent Flag set to 0

**Uplink:**
- HARQ UL MAP Allocation IE
- Persistent HARQ UL MAP Allocation IE with Persistent Flag set to 0

6.3.26.4 Error handling procedures

The BS may assign to MSs that have persistent resource allocations a persistent MAP NACK channel and a non-persistent MAP ACK channel. The MAP NACK channel is persistent for the whole time the persistent resource allocation exists.

The MS shall transmit at the MAP ACK signal via assigned MAP ACK channel to acknowledge the correct reception of a Persistent HARQ DL MAP IE or Persistent HARQ UL MAP IE, which includes the RCID of the MS. The MAP ACK channel carries one codeword indicating an ACK as described in 8.4.11.16.

The MAP NACK channel is a shared channel used by the MS to indicate MAP decoding errors. The BS may assign the same MAP NACK channel index to one or more MSs therefore more than one MS may transmit using a particular MAP NACK channel at the same time. The MAP NACK channel carries one codeword indicating a NACK as described in 8.4.11.17.

The MAP ACK and MAP NACK channels correspond to resources within the Fast Feedback region (8.4.11).

6.3.26.4.1 Maximum Number of Persistent Allocations

The maximum number of DL persistent allocations for a specific MS per frame per Persistent Region ID is 1. The maximum number of UL persistent allocations for a specific MS per frame per Persistent Region ID is 1. Therefore, if an MS has an existing persistent allocation for a particular Persistent Region ID valid in a...
particular frame and receives a new persistent allocation for the same Persistent Region ID valid in the same frame, the new persistent allocation replaces the original allocation (i.e., the original persistent allocation is de-allocated). When resource shifting is enabled, the BS shall not de-allocate the persistent allocation by assigning a new allocation.

6.3.26.4.2 MAP ACK channel

The MS shall transmit a MAP ACK indication to the BS using the assigned MAP ACK channel upon receipt of a Persistent HARQ DL MAP IE, which includes the RCID of the MS. Similarly, the MS shall transmit a MAP ACK indication to the BS using the assigned MAP ACK channel index upon receipt of a Persistent HARQ UL MAP IE, which includes the RCID of the MS. The MAP ACK channel shall be transmitted in the relevant UL subframe, as described in 6.3.7.5. The BS should interpret the absence of an acknowledgement on the MAP ACK channel as a NACK. Procedures for error recovery from MAP loss indicated by the MAP ACK channel are left to vendors’ implementation and are out of scope of this standard.

Once the MS has successfully received the persistent allocation IE and if a valid MAP NACK channel is assigned for the allocation, the MS shall indicate subsequent MAP losses using the designated MAP NACK channel as described in 6.3.26.4.3.

6.3.26.4.3 MAP NACK channel

6.3.26.4.3.1 Downlink operation

If the MS fails to decode the DL-MAP or the compressed DL-MAP in a frame which is relevant to a frame in which it has a persistent DL resource allocation, the MS may send a MAP NACK on its assigned MAP NACK Channel in the frame following the relevant UL subframe as shown in Figure 155. The MS shall not transmit a MAP NACK if it successfully decodes the DL-MAP or the compressed DL-MAP and fails to decode one or more SUB-DL-UL-MAPs.

Upon reception of the MAP NACK indication, the BS should determine if the persistent allocation needs to be updated.

Figure 155—Example MAP NACK Relevance
6.3.26.4.3.2 Uplink operation

If the MS fails to decode the UL-MAP or the compressed UL-MAP in a frame which is relevant to a frame in which it has a persistent UL resource allocation, the MS may send a MAP NACK on its assigned MAP NACK Channel in the frame following the relevant UL subframe as shown in Figure 155. The MS shall not transmit a MAP NACK if it successfully decodes the UL-MAP or the compressed UL-MAP and fails to decode one or more SUB-DL-UL-MAPs.

Upon reception of the MAP NACK indication, the BS should determine if the persistent allocation needs to be updated.

6.3.26.4.4 Error Correction Information

If a MAP NACK is detected at the BS, the BS may either make absolute updates to all affected MSs, where an absolute update means that the base station transmits an assignment to the mobile station, which does not depend on knowledge of a previous assignment, or retransmit de-allocation command of frame \( K – allocation\ period (ap) \) by sending subburst IE with the Retransmission Flag set to 1. The BS may use other information, such as traffic ACK for DL allocations and UL traffic detection for UL allocations, to determine that error correction information is not needed. It is left to vendor’s implementation whether to send error correction information, and if error correction information is sent, which types of commands, i.e., deallocation with retransmission flag = 1 or absolute updates to all affected MSs, the base station sends. An MS shall be able to recover persistent allocation by both types of commands.

6.3.26.4.5 Change indicator

A Change Indicator for each Persistent Region ID shall be included in the Persistent HARQ DL MAP IE.

A Change Indicator for each Persistent Region ID shall be included in the Persistent HARQ UL MAP IE.

A Change indicator in frame \( K \) shall be used by the MSs who failed to receive the DL-MAP or UL-MAP in frame \( K – ap \) to decide if they can resume using their persistent allocation in frame \( K \).

An MS that failed to receive the DL-MAP or UL-MAP in frame \( K – ap \) shall interpret the change indicator= ‘0’ as there were no changes, such as deallocation, Persistent HARQ Region change in the Persistent HARQ DL MAP IE or Persistent HARQ UL MAP IE in \( K – ap \).

An MS that failed to receive the DL-MAP or UL-MAP in frame \( K – ap \) shall interpret the change indicator = ‘1’ as there were change(s) in the Persistent HARQ DL MAP IE or Persistent HARQ UL MAP IE in \( K – ap \).

The base station sets the change indicator to 0 in frame \( K \) in case there are sufficient evidences that all the MSs that involved in the changes in frame \( K – ap \) have received the change information.

6.3.26.4.6 Retransmission flag

A retransmission flag shall be included in the deallocation command of the Persistent HARQ DL MAP IE and the Persistent HARQ UL MAP IE. The retransmission flag shall be set to 1 to indicate that this deallocation command was transmitted in frame \( K – ap \) and is retransmitted for MS who missed the MAP in frame \( K – ap \), to recover the persistent allocation. The MS, who failed to receive the DL-MAP or UL-MAP in frame \( K – ap \) shall process the deallocation command with retransmission flag equal to 1 to recover the MAP loss in frame \( K – ap \), while the MS, who received the MAP in frame \( K – ap \), shall disregard the deallocation command with retransmission flag equal to 1 in frame \( K \). The retransmission flag shall be set to 0 to indicate that this deallocation command is transmitted to deallocate the persistent allocated resource in frame \( K \).
6.3.26.4.7 Error recovery

6.3.26.4.7.1 Downlink persistent allocation error recovery

The MS that failed to decode the DL-MAP in frame $K$ shall stop using the persistent allocation, including the data allocation, the MAP NACK allocation, and the HARQ ACK channel allocation, if any, in frame $K + \text{allocation period (ap)}$, where $ap$ is a field of the Persistent HARQ DL MAP IE (8.4.5.3.29) if any one of the following conditions is true in frame $K + ap$.

— Condition 1. The MS receives a Persistent HARQ DL MAP IE, which has the Change Indicator for the assigned Persistent Region ID set to 1.

Otherwise, the MS shall resume its persistent allocation, subject to any changes to its persistent allocation, for example de-allocation or reallocation, contained in the Persistent HARQ DL MAP IE in frame $K + ap$.

If the MS fails to decode the DL-MAP in a frame (frame$_{MAP}$) which is relevant to a frame in which it has a persistent DL resource allocation (frame $K$) and fails to decode the DL-MAP in frame$_{MAP} + ap$, and if MAP NACK channel is allocated to the MS (MAP NACK field is $\neq \text{0b}111111$), the MS should attempt to send the Persistent Allocation Error Event extended subheader to the BS and shall stop using the persistent assignment including the data allocation, the MAP NACK allocation, and the HARQ ACK channel allocation, if any.

When MAP NAK channel is not allocated (MAP NACK field = 0b111111) to an MS and the MS failed to decode the DL-MAP in frame$_{MAP}$, the MS may resume using the persistent allocation in frame$_{MAP} + N \times \text{Allocation Period (ap)}$, where $N$ is the number of relevant MAPs and $ap$ is a field of the Persistent HARQ DL MAP IE if the change indicator for the assigned Persistent Region ID is set to 0 in frame$_{MAP} + N \times ap$. If the MS successfully decodes the DL-MAP at frame$_{MAP} + N \times ap$ and the change indicator for the assigned Persistent Region ID is set to 1, the MS should attempt to send the Persistent Allocation Error Event extended subheader to the BS and shall stop using the persistent assignment including the data and the ACK channel allocation.

6.3.26.4.7.2 Uplink persistent allocation error recovery

The MS that failed to decode the UL-MAP in a frame (frame$_{MAP}$), which is relevant to a frame in which it has a persistent UL resource allocation (frame $K$), shall stop using the persistent allocation, including the data allocation, and the MAP NACK allocation, in the frame relevant to frame $K + \text{Allocation Period (ap)}$, where $ap$ is a field of the Persistent HARQ UL MAP IE (8.4.5.4.28) if any one of the following condition is true in frame$_{MAP} + ap$.

— Condition 1. The MS receives a Persistent HARQ UL MAP IE for the assigned Persistent Region ID, which has the Change Indicator for the assigned Persistent Region ID set to 1.

Otherwise, the MS shall resume its persistent allocation, subject to any changes to its persistent allocation, for example de-allocation or reallocation, contained in the Persistent HARQ UL MAP IE in frame$_{MAP} + ap$.

If the MS fails to decode the UL-MAP in a frame (frame$_{MAP}$) which is relevant to a frame in which it has a persistent DL/UL resource allocation (frame $K$) and fails to decode the UL-MAP in frame$_{MAP} + ap$, and if MAP NACK channel is allocated to the MS (MAP NACK field is $\neq \text{0b}111111$), the MS shall transmit an indication to the BS and shall stop using the persistent assignment including the data allocation and the MAP NACK allocation. The allocation period is indicated in the subburst IE of the Persistent HARQ UL MAP IE.

When MAP NAK channel is not allocated (MAP NACK field = 0b111111) to an MS and the MS failed to decode the UL-MAP in frame$_{MAP}$, the MS may resume using the persistent allocation in frame$_{MAP} + N \times ap$, where $N$ is the number of relevant MAPs and $ap$ is a field of the Persistent HARQ UL MAP IE the change.
indicator for the assigned Persistent Region ID is set to 0 in \(frame_{MAP} + N \times ap\). If the MS successfully decodes the UL-MAP at \(frame_{MAP} + N \times ap\) and the change indicator for the assigned Persistent Region ID is set to 1, the MS should attempt to send the Persistent Allocation Error Event extended subheader to the BS and shall stop using the persistent assignment including the data and the ACK channel allocation.

### 6.3.27 Emergency Service

Emergency Service is defined as a service that would provide the public with alerts on imminent emergency events, such as earthquake, storm, tidal wave, etc. The alerts would target subscribers in a specific geographical location. The BS shall transmit the Emergency Service compound TLV via the DCD message (see Table 575).

The Emergency Service compound TLV shall contain the CIDs for Emergency Service TLV encoding required for an MS to identify a MAC PDU containing Emergency Service Message (ESM) (see Table 575). The Emergency Service compound TLV may include a “CS type for Emergency Service TLV” (see Table 578). If an MS supports the CS type used for Emergency Service, the MS shall receive and decode the Emergency Service message when there is one. CIDs specified by the “CIDs for Emergency Service TLV” encoding (see Table 578) shall not be assigned to the MS’s connection which is established via DSA transaction. The BS may also broadcast emergency-related helpful alert information (e.g., commercial advertisement and announcements that may be of interest to the public) via ESM. The Emergency Service connection shall use neither header compression nor PHS.

The BS may broadcast ESM(s) either through an MBS permutation zone or through a normal DL zone (e.g., PUSC, FUSC and so on). If the BS decides to broadcast the ESM(s) through the MBS permutation zone, the BS shall transmit MBS_MAP_IE with indication of an ESM existence in the MBS permutation zone (see 8.4.5.3.12). Even if an MS is not monitoring the MBS channel, the MS shall check for and decode at least these two parameters in an MBS_MAP IE (the Macro diversity enhanced and the Existence of Emergency Service Message). If the MS detects the existence of ESM(s) sent through the MBS permutation zone, the MS shall decode the MBS_MAP message in order to identify the MBS data burst in which the MAC PDU containing Emergency Service Message(s) will be transmitted.

Instead of Broadcast Control Pointer IE (see 8.4.5.3.25), an Extended Broadcast Control Pointer IE (see 8.4.5.3.31) may be used to indicate the frame in which ESM(s) are going to be transmitted. When an MS in Idle Mode or Sleep Mode receives the Extended Broadcast Control Pointer IE with Type = 0x0 during its own interval (i.e., Paging Listening Interval in Idle Mode or Listening Window in Sleep Mode), the MS shall wake up in the frame specified by the Extended Broadcast Control Pointer IE and stay awake during the Transmission Duration indicated by the Extended Broadcast Control Pointer IE.
7. Security sublayer

The security sublayer provides subscribers with privacy, authentication, or confidentiality\(^{19}\) across the broadband wireless network. It does this by applying cryptographic transforms to MAC PDUs carried across connections between SS and BS.

In addition, the security sublayer provides operators with strong protection from theft of service. The BS protects against unauthorized access to these data transport services by securing the associated service flows across the network. The security sublayer employs an authenticated client/server key management protocol in which the BS, the server, controls distribution of keying material to client SS. Additionally, the basic security mechanisms are strengthened by adding digital-certificate-based SS device-authentication to the key management protocol.

If during capabilities negotiation, the SS specifies that it does not support IEEE 802.16 security, step of authorization and key exchange shall be skipped. The BS, if provisioned so, shall consider the SS authenticated; otherwise, the SS shall not be serviced. Neither key exchange nor data encryption performed.

7.1 Architecture

Privacy has two component protocols as follows:

a) An encapsulation protocol for securing packet data across the fixed BWA network. This protocol defines a set of supported cryptographic suites, i.e., pairings of data encryption and authentication algorithms, and the rules for applying those algorithms to a MAC PDU payload.

b) A key management protocol (PKM) providing the secure distribution of keying data from the BS to the SS. Through this key management protocol, the SS and the BS synchronize keying data; in addition, the BS uses the protocol to enforce conditional access to network services.

The protocol stack for the security components of the system are shown in Figure 156.

---

\(^{19}\)In security parlance, confidentiality = privacy + authenticity.
— PKM Control Management: This stack controls all security components. Various keys are derived and generated in this stack.
— Traffic Data Encryption/Authentication Processing: This stack encrypts or decrypts the traffic data and executes the authentication function for the traffic data.
— Control Message Processing: This stack processes the various PKM-related MAC messages.
— Message Authentication Processing: This stack executes message authentication function. The HMAC, CMAC, or several short-HMACs can be supported.
— RSA-based Authentication: This stack performs the RSA-based authentication function using the SS’s X.509 digital certificate and the BS’s X.509 digital certificate, when the RSA-based authorization is selected as an authorization policy between an SS and a BS.
— EAP Encapsulation/Decapsulation: This stack provides the interface with the EAP layer, when the EAP-based authorization or the authenticated EAP-based authorization is selected as an authorization policy between an SS and a BS.
— Authorization/SA Control: This stack controls the authorization state machine and the traffic encryption key state machine.
— EAP and EAP Method Protocol: These stacks are outside of the scope of this standard.

7.1.1 Secure encapsulation of MAC PDUs

Encryption services are defined as a set of capabilities within the MAC security sublayer. MAC header information specific to encryption is allocated in the generic MAC header format.

Encryption is always applied to the MAC PDU payload when required by the selected ciphersuite; the generic MAC header is not encrypted. All MAC management messages shall be sent in the clear to facilitate registration, ranging, and normal operation of the MAC.

The format of MAC PDUs carrying encrypted packet data payloads is specified in 6.3.3.6.

7.1.2 Key management protocol

The PKM protocol allows for both mutual authentication and unilateral authentication (e.g., where the BS authenticates SS, but not vice versa). It also supports periodic reauthentication/reauthorization and key refresh. The key management protocol uses either EAP [IETF RFC 3748] or X.509 digital certificates [IETF RFC 3280] together with RSA public-key encryption algorithm [PKCS #1] or a sequence starting with RSA authentication and followed by EAP authentication. It uses strong encryption algorithms to perform key exchanges between an SS and BS.

The PKM’s authentication protocol establishes a shared secret (i.e., the AK) between the SS and the BS. The shared secret is then used to secure subsequent PKM exchanges of TEKs. This two-tiered mechanism for key distribution permits refreshing of TEKs without incurring the overhead of computation-intensive operations.

A BS authenticates a client SS during the initial authorization exchange. Each SS presents its credentials, which shall be a unique X.509 digital certificate issued by the SS’s manufacturer (in the case of RSA authentication) or a operator-specified credential (in the case of EAP-based authentication).

The BS associates an SS’s authenticated identity to a paying subscriber and hence to the data services that subscriber is authorized to access.

Since the BS authenticates the SS, it may protect against an attacker employing a cloned SS that masquerades as a legitimate subscriber’s SS.
The traffic key management portion of the PKM protocol adheres to a client/server model, where the SS (a PKM “client”) requests keying material and the BS (a PKM “server”) responds to those requests. This model ensures that individual SS clients receive only keying material for which they are authorized.

The PKM protocol uses MAC management messaging, i.e., PKM-REQ and PKM-RSP messages defined in 6.3.2.3. The PKM protocol is defined in detail in 7.2.

**7.1.3 Authentication protocol**

An SS uses the PKM protocol to obtain authorization and traffic keying material from the BS and to support periodic reauthorization and key refresh.

PKM supports the following two distinct authentication protocol mechanisms:

- RSA protocol [PKCS #1 v2.1 with SHA-1(FIPS 186-2)] (support is mandatory in PKMv1; support is optional in PKMv2)
- Extensible Authentication Protocol (optional unless specifically required)

**7.1.3.1 PKM RSA authentication**

The PKM RSA authentication protocol uses X.509 digital certificates [IETF RFC 3280], the RSA public-key encryption algorithm [PKCS #1] that binds public RSA encryption keys to MAC addresses of SSs.

A BS authenticates a client SS during the initial authorization exchange. Each SS carries a unique X.509 digital certificate issued by the SS’s manufacturer. The digital certificate contains the SS’s Public Key and SS MAC address. When requesting an AK, an SS presents its digital certificate to the BS. The BS verifies the digital certificate, and then uses the verified Public Key to encrypt an AK, which the BS then sends back to the requesting SS.

All SSs using RSA authentication shall have factory-installed RSA private/public key pairs or provide an internal algorithm to generate such key pairs dynamically. If an SS relies on an internal algorithm to generate its RSA key pair, the SS shall generate the key pair prior to its first AK exchange, described in 7.2.1. All SSs with factory-installed RSA key pairs shall also have factory-installed X.509 certificates. All SSs that rely on internal algorithms to generate an RSA key pair shall support a mechanism for installing a manufacturer-issued X.509 certificate following key generation.

**7.1.3.2 PKM EAP authentication**

PKM EAP Authentication uses Extensible Authentication Protocol [IETF RFC 3748] in conjunction with an operator-selected EAP Method (e.g., EAP-TLS [IETF RFC 2716]). The EAP method will use a particular kind of credential – such as an X.509 certificate in the case of EAP-TLS, or a Subscriber Identity Module in the case of EAP-SIM.

The particular credentials and EAP methods that are to be used are outside of the scope of this specification. However, the EAP method selected should fulfill the “mandatory criteria” listed in section 2.2 of IETF RFC 4017. Use of an EAP method not meeting these criteria may lead to security vulnerabilities.

During reauthentication, the EAP transfer messages are protected with an HMAC/CMAC Tuple. The BS and SS shall discard unprotected EAP transfer messages, or EAP transfer messages with invalid HMAC/CMAC Digests during reauthentication.

**7.1.4 Mapping of connections to SAs**

The following rules for mapping connections to SAs apply:
a) All transport connections shall be mapped to an existing SA.
b) Multicast transport connections may be mapped to any Static or Dynamic SA.
c) The secondary management connection shall be mapped to the Primary SA.
d) The basic and the primary management connections shall not be mapped to an SA.

The actual mapping is achieved by including the SAID of an existing SA in the DSA-xxx messages together with the CID. No explicit mapping of secondary management connection to the Primary SA is required.

7.1.5 Cryptographic suite

A cryptographic suite is the SA’s set of methods for data encryption, data authentication, and TEK exchange. A cryptographic suite is specified as described in 11.9.14. The cryptographic suite shall be one of the ones listed in Table 601.

7.2 PKM protocol

There are two Privacy Key Management Protocols supported in this standard: PKM version 1 and PKMv2 with more enhanced features such as new key hierarchy, AES-CMAC, AES key wraps, and MBS.

7.2.1 PKM version 1

7.2.1.1 Security associations (SAs)

A security association (SA) is the set of security information a BS and one or more of its client SSs share in order to support secure communications across the IEEE 802.16 network. Three types of SAs are defined: Primary, Static, and Dynamic. Each SS establishes a primary security association during the SS initialization process. Static SAs are provisioned within the BS. Dynamic SAs are established and eliminated, on the fly, in response to the initiation and termination of specific service flows. Both Static and Dynamic SAs may be shared by multiple SSs.

An SA’s shared information shall include the cryptographic suite employed within the SA. The shared information may include TEKs and Initialization Vectors. The exact content of the SA is dependent on the SA’s cryptographic suite.

SAs are identified using SAIDs.

Each SS shall establish an exclusive Primary SA with its BS. The SAID of any SS’s Primary SA shall be equal to the Basic CID of that SS.

Using the PKM protocol, an SS requests from its BS an SA’s keying material. The BS shall ensure that each client SS only has access to the SAs it is authorized to access.

An SA’s keying material [e.g., data encryption standard (DES) key and CBC IV] has a limited lifetime. When the BS delivers SA keying material to an SS, it also provides the SS with that material’s remaining lifetime. It is the responsibility of the SS to request new keying material from the BS before the set of keying material that the SS currently holds expires at the BS. Should the current keying material expire before a new set of keying material is received, the SS shall perform network entry as described in 6.3.9.

In certain cryptographic suites, key lifetime may be limited by the exhaustion rate of a number space, e.g., the PN of AES in CCM mode [i.e., CTR mode with cipher block chaining message authentication code (CBC-MAC)]. In this case, the key ends either at the expiry of the key lifetime or the exhaustion of the number space, which ever is earliest. Note that in this case, security is not determined by the key lifetime.
7.2.1.2 SS authorization and AK exchange overview

SS authorization, controlled by the Authorization state machine, is the process of the BS’s authenticating a client SS’s identity:

a) The BS and SS establish a shared AK by RSA from which a key encryption key (KEK) and message authentication keys are derived.
b) The BS provides the authenticated SS with the identities (i.e., the SAIDs) and properties of Primary and Static SAs for which the SS is authorized to obtain keying information.

After achieving initial authorization, an SS periodically reauthorizes with the BS; reauthorization is also managed by the SS’s Authorization state machine. TEK state machines manage the refreshing of TEKs.

7.2.1.2.1 Authorization via RSA authentication protocol

An SS begins authorization by sending an Authentication Information message to its BS. The Authentication Information message contains the SS manufacturer’s X.509 certificate, issued by the manufacturer itself or by an external authority. The Authentication Information message is strictly informative; i.e., the BS may choose to ignore it. However, it does provide a mechanism for a BS to learn the manufacturer certificates of its client SS.

The SS sends an Authorization Request message to its BS immediately after sending the Authentication Information message. This is a request for an AK, as well as for the SAIDs identifying any Static SAs the SS is authorized to participate in. The Authorization Request includes

— A manufacturer-issued X.509 certificate.
— A description of the cryptographic algorithms the requesting SS supports. An SS’s cryptographic capabilities are presented to the BS as a list of cryptographic suite identifiers, each indicating a particular pairing of packet data encryption and packet data authentication algorithms the SS supports.
— The SS’s Basic CID. The Basic CID is the first static CID the BS assigns to an SS during initial ranging—the primary SAID is equal to the Basic CID.

In response to an Authorization Request message, a BS validates the requesting SS’s identity, determines the encryption algorithm and protocol support it shares with the SS, activates an AK for the SS, encrypts it with the SS’s public key, and sends it back to the SS in an Authorization Reply message. The authorization reply includes

— An AK encrypted with the SS’s public key.
— A 4-bit key sequence number, used to distinguish between successive generations of AKs.
— A key lifetime.
— The identities (i.e., the SAIDs) and properties of the single primary and zero or more Static SAs for which the SS is authorized to obtain keying information.

While the Authorization Reply shall identify Static SAs in addition to the Primary SA whose SAID matches the requesting SS’s Basic CID, the Authorization Reply shall not identify any Dynamic SAs.

The BS, in responding to an SS’s Authorization Request, shall determine whether the requesting SS, whose identity can be verified via the X.509 digital certificate, is authorized for basic unicast services, and what additional statically provisioned services (i.e., Static SAIDs) the SS’s user has subscribed for. Note that the protected services a BS makes available to a client SS can depend upon the particular cryptographic suites for which the SS and the BS share support.
An SS shall periodically refresh its AK by reissuing an Authorization Request to the BS. Reauthorization is identical to authorization with the exception that the SS does not send Authentication Information messages during reauthorization cycles. The description of the authorization state machine in 7.2.1.6 clearly indicates when Authentication Information messages are sent.

To avoid service interruptions during reauthorization, successive generations of the SS’s AKs have overlapping lifetimes. Both the SS and BS shall be able to support up to two simultaneously active AKs during these transition periods. The operation of the Authorization state machine’s Authorization Request scheduling algorithm, combined with the BS’s regimen for updating and using a client SS’s AKs (see 7.3), ensures that the SS can refresh.

7.2.1.3 TEK exchange overview

7.2.1.3.1 TEK exchange overview for PMP topology

Upon achieving authorization, an SS starts a separate TEK state machine for each of the SAIDs identified in the Authorization Reply message. Each TEK state machine operating within the SS is responsible for managing the keying material associated with its respective SAID. TEK state machines periodically send Key Request messages to the BS, requesting a refresh of keying material for their respective SAIDs.

The BS responds to a Key Request with a Key Reply message, containing the BS’s active keying material for a specific SAID.

The TEK is encrypted using appropriate KEK derived from the AK.

Note that at all times the BS maintains two active sets of keying material per SAID. The lifetimes of the two generations overlap so that each generation becomes active halfway through the life of its predecessor and expires halfway through the life of its successor. A BS includes in its Key Replies both of an SAID’s active generations of keying material.

The Key Reply provides the requesting SS, in addition to the TEK and CBC IV, the remaining lifetime of each of the two sets of keying material. The receiving SS uses these remaining lifetimes to estimate when the BS will invalidate a particular TEK and, therefore, when to schedule future Key Requests so that the SS requests and receives new keying material before the BS expires the keying material the SS currently holds.

The operation of the TEK state machine’s Key Request scheduling algorithm, combined with the BS’s regimen for updating and using an SAID’s keying material (see 7.4), ensures that the SS will be able to continually exchange encrypted traffic with the BS.

A TEK state machine remains active as long as

a) The SS is authorized to operate in the BS’s security domain, i.e., it has a valid AK, and
b) The SS is authorized to participate in that particular SA, i.e., the BS continues to provide fresh keying material during rekey cycles.

The parent Authorization state machine stops all of its child TEK state machines when the SS receives from the BS an Authorization Reject during a reauthorization cycle. Individual TEK state machines can be started or stopped during a reauthorization cycle if an SS’s Static SAID authorizations changed between successive reauthorizations.

Communication between Authorization and TEK state machines occurs through the passing of events and protocol messaging. The Authorization state machine generates events (i.e., Stop, Authorized, Authorization Pending, and Authorization Complete events) that are targeted at its child TEK state machines. TEK state
machines do not target events at their parent Authorization state machine. The TEK state machine affects the Authorization state machine indirectly through the messaging a BS sends in response to an SS’s requests: a BS may respond to a TEK machine’s Key Requests with a failure response (i.e., Authorization Invalid message) to be handled by the Authorization state machine.

7.2.1.4 Security capabilities selection

As part of their authorization exchange, the SS provides the BS with a list of all the cryptographic suites (pairing of data encryption and data authentication algorithms) the SS supports. The BS selects from this list a single cryptographic suite to employ with the requesting SS’s primary SA. The Authorization Reply the BS sends back to the SS includes a primary SA-Descriptor that, among other things, identifies the cryptographic suite the BS selected to use for the SS’s primary SA. A BS shall reject the authorization request if it determines that none of the offered cryptographic suites are satisfactory.

The Authorization Reply also contains an optional list of static SA-Descriptors; each static SA-Descriptor identifies the cryptographic suite employed within the SA. The selection of a static SA’s cryptographic suite is typically made independent of the requesting SS’s cryptographic capabilities. A BS may include in its Authorization Reply static SA-Descriptors identifying cryptographic suites the requesting SS does not support; if this is the case, the SS shall not start TEK state machines for static SAs whose cryptographic suites the SS does not support.

If the SA holds an encryption method, all MAC PDUs sent with CIDs linked to this SA shall have EC bit set to ‘1’ in the Generic MAC Header. If the SA has no encryption method, the EC bit shall be set to ‘0’ in the Generic MAC Header. Other combinations are not allowed; MAC PDUs presenting other combinations should be discarded.

7.2.1.5 Authorization state machine

The Authorization state machine consists of six states and eight distinct events (including receipt of messages) that can trigger state transitions. The Authorization finite state machine (FSM) is presented below in a graphical format, as a state flow model (Figure 157), and in a tabular format, as a state transition matrix (Table 202).

The state flow diagram depicts the protocol messages transmitted and internal events generated for each of the model’s state transitions; however, the diagram does not indicate additional internal actions, such as the clearing or starting of timers, that accompany the specific state transitions. Accompanying the state transition matrix is a detailed description of the specific actions accompanying each state transition; the state transition matrix shall be used as the definitive specification of protocol actions associated with each state transition.

The following legend applies to the Authorization State Machine flow diagram depicted in Figure 157.

a) Ovals are states.
b) Events are in italics.
c) Messages are in normal font.
d) State transitions (i.e., the lines between states) are labeled with <what causes the transition>/<messages and events triggered by the transition>. So “timeout/Auth Request” means that the state received a “timeout” event and sent an Authorization Request (“Auth Request”) message. If there are multiple events or messages before the slash “/” separated by a comma, any of them can cause the transition. If there are multiple events or messages listed after the slash, all of the specified actions shall accompany the transition.
The Authorization state transition matrix presented in Table 202 lists the six Authorization machine states in the topmost row and the eight Authorization machine events (includes message receipts) in the leftmost column. Any cell within the matrix represents a specific combination of state and event, with the next state (the state transitioned to) displayed within the cell. For example, cell 4-B represents the receipt of an Authorization Reply (Auth Reply) message when in the Authorize Wait (Auth Wait) state. Within cell 4-B is the name of the next state, “Authorized.” Thus, when an SS’s Authorization state machine is in the Auth Wait state and an Auth Reply message is received, the Authorization state machine will transition to the Authorized state. In conjunction with this state transition, several protocol actions shall be taken; these are described in the listing of protocol actions, under the heading 4-B, in 7.2.1.5.5.

A shaded cell within the state transition matrix implies that either the specific event cannot or should not occur within that state, and if the event does occur, the state machine shall ignore it. For example, if an Auth Reply message arrives when in the Authorized state, that message should be ignored (cell 4-C). The SS may, however, in response to an improper event, log its occurrence, generate an SNMP event, or take some other vendor-defined action. These actions, however, are not specified within the context of the Authorization state machine, which simply ignores improper events.

7.2.1.5.1 States

— **Start:** This is the initial state of the FSM. No resources are assigned to or used by the FSM in this state—e.g., all timers are off, and no processing is scheduled.

— **Authorize Wait (Auth Wait):** The SS has received the “Communication Established” event indicating that it has completed basic capabilities negotiation with the BS. In response to receiving the event, the SS has sent both an Authentication Information and an Auth Request message to the BS and is waiting for the reply.

— **Authorized:** The SS has received an Auth Reply message that contains a list of valid SAIDs for this SS. At this point, the SS has a valid AK and SAID list. Transition into this state triggers the creation of one TEK FSM for each of the SS’s privacy-enabled SAIDs.

— **Reauthorize Wait (Reauth Wait):** The SS has an outstanding reauthorization request. The SS was either about to expire (see Authorization Grace Time in Table 555) its current authorization or
received an indication (an Authorization Invalid message from the BS) that its authorization is no longer valid. The SS sent an Auth Request message to the BS and is waiting for a response.

- **Authorize Reject Wait (Auth Reject Wait):** The SS received an Authorization Reject (Auth Reject) message in response to its last Auth Request. The Auth Reject’s error code indicated the error was not of a permanent nature. In response to receiving this reject message, the SS set a timer and transitioned to the Auth Reject Wait state. The SS remains in this state until the timer expires.

- **Silent:** The SS received an Auth Reject message in response to its last Auth Request. The Auth Reject’s error code indicated the error was of a permanent nature. This triggers a transition to the Silent state, where the SS is not permitted to pass subscriber traffic. The SS shall, however, respond to management messages from the BS issuing the Perm Auth Reject.

**7.2.1.5.2 Messages**

Note that the message formats are defined in detail in 6.3.2.3.9.

- **Authorization Request (Auth Request):** Request an AK and list of authorized SAIDs. Sent from SS to BS.
- **Authorization Reply (Auth Reply):** Receive an AK and list of authorized, static SAIDs. Sent from BS to SS. The AK is encrypted with the SS’s public key.
- **Authorization Reject (Auth Reject):** Attempt to authorize was rejected. Sent from the BS to the SS.
- **Authorization Invalid (Auth Invalid):** The BS may send an Authorization Invalid message to a client SS as follows:
  - An unsolicited indication, or
  - A response to a message received from that SS.

In either case, the Auth Invalid message instructs the receiving SS to reauthorize with its BS.

The BS responds to a Key Request with an Auth Invalid message if (1) the BS does not recognize the SS as being authorized (i.e., no valid AK associated with SS) or (2) verification of the Key

Request’s keyed message digest (in HMAC-Digest attribute) failed. Note that the Authorization Invalid event, referenced in both the state flow diagram and the state transition matrix, signifies either the receipt of an Auth Invalid message or an internally generated event.

- **Authentication Information (Auth Info):** The Auth Info message contains the SS manufacturer’s X.509 Certificate, issued by an external authority. The Auth Info message is strictly an informative message the SS sends to the BS; with it, a BS may dynamically learn the manufacturer certificate of client SS. Alternatively, a BS may require out-of-band configuration of its list of manufacturer certificates.

### 7.2.1.5.3 Events

- **Communication Established:** The Authorization state machine generates this event upon entering the Start state if the MAC has completed basic capabilities negotiation. If the basic capabilities negotiation is not complete, the SS sends a Communication Established event to the Authorization FSM upon completing basic capabilities negotiation. The Communication Established event triggers the SS to begin the process of getting its AK and TEKs.
- **Timeout:** A retransmission or wait timer timed out. Generally a request is resent.
- **Authorization Grace Timeout (Auth Grace Timeout):** The Authorization Grace timer timed out. This timer fires a configurable amount of time (the Authorization Grace Time) before the current authorization is supposed to expire, signalling the SS to reauthorize before its authorization actually expires. The Authorization Grace Time takes the default value from Table 555 or may be specified in a configuration setting within the Auth Reply message.
- **Reauthorize (Reauth):** SS’s set of authorized static SAIDs may have changed. This event may be generated in response to an SNMP set and meant to trigger a reauthorization cycle.
- **Authorization Invalid (Auth Invalid):** This event is internally generated by the SS when there is a failure authenticating a Key Reply or Key Reject message, or externally generated by the receipt of an Auth Invalid message, sent from the BS to the SS. A BS responds to a Key Request with an Auth Invalid if verification of the request’s message authentication code fails. Both cases indicate BS and SS have lost AK synchronization.

A BS may also send to an SS an unsolicited Auth Invalid message, forcing an Auth Invalid event.

- **Permanent Authorization Reject (Perm Auth Reject):** The SS receives an Auth Reject in response to an Auth Request. The error code in the Auth Reject indicates the error is of a permanent nature. What is interpreted as a permanent error is subject to administrative control within the BS. Auth Request processing errors that can be interpreted as permanent error conditions include the following:
  - Unknown manufacturer (do not have CA certificate of the issuer of the SS Certificate).
  - Invalid signature on SS certificate.
  - ASN.1 parsing failure.
  - Inconsistencies between data in the certificate and data in accompanying PKM data attributes.
  - Incompatible security capabilities.

When an SS receives an Auth Reject indicating a permanent failure condition, the Authorization State machine moves into a Silent state, where the SS is not permitted to pass subscriber traffic. The SS shall, however, respond to management messages from the BS issuing the Perm Auth Reject. The managed SS may also issue an SNMP Trap upon entering the Silent state.

- **Authorization Reject (Auth Reject):** The SS receives an Auth Reject in response to an Auth Request. The error code in the Auth Reject does not indicate the failure was due to a permanent error condition. As a result, the SS’s Authorization state machine shall set a wait timer and transition into the Auth Reject Wait State. The SS shall remain in this state until the timer expires, at which time it shall reattempt authorization.

**NOTE**—The following events are sent by an Authorization state machine to the TEK state machine:
— [TEK] Stop: Sent by the Authorization FSM to an active (non-START state) TEK FSM to terminate the FSM and remove the corresponding SAI’d’s keying material from the SS’s key table.
— [TEK] Authorized: Sent by the Authorization FSM to a nonactive (START state), but valid TEK FSM.
— [TEK] Authorization Pending (Auth Pend): Sent by the Authorization FSM to a specific TEK FSM to place that TEK FSM in a wait state until the Authorization FSM can complete its reauthorization operation.
— [TEK] Authorization Complete (Auth Comp): Sent by the Authorization FSM to a TEK FSM in the Operational Reauthorize Wait (Op Reauth Wait) or Rekey Reauthorize Wait (Rekey Reauth Wait) states to clear the wait state begun by a TEK FSM Authorization Pending event.

7.2.1.5.4 Parameters

All configuration parameter values take the default values from Table 555 or may be specified in the Auth Reply message.

— Authorize Wait Timeout (Auth Wait Timeout): Timeout period between sending Authorization Request messages from Auth Wait state (see 11.9.18.2).
— Authorization Grace Timeout (Auth Grace Timeout): Amount of time before authorization is scheduled to expire that the SS starts reauthorization (see 11.9.18.3).
— Authorize Reject Wait Timeout (Auth Reject Wait Timeout): Amount of time an SS’s Authorization FSM remains in the Auth Reject Wait state before transitioning to the Start state (see 11.9.18.7).

7.2.1.5.5 Actions

Actions taken in association with state transitions are listed by <event> (<rcvd message>) --> <state> below:

1-A Start (Communication Established) → Auth Wait
   a) Send Auth Info message to BS
   b) Send Auth Request message to BS
   c) Set Auth Request retry timer to Auth Wait Timeout

2-B Auth Wait (Auth Reject) → Auth Reject Wait
   a) Clear Auth Request retry timer
   b) Set a wait timer to Auth Reject Wait Timeout

2-D Reauth Wait (Auth Reject) → Auth Reject Wait
   a) Clear Auth Request retry timer
   b) Generate TEK FSM Stop events for all active TEK state machines
   c) Set a wait timer to Auth Reject Wait Timeout

3-B Auth Wait (Perm Auth Reject) → Silent
   a) Clear Auth Request retry timer
   b) Disable all forwarding of SS traffic

3-D Reauth Wait (Perm Auth Reject) → Silent
   a) Clear Auth Request retry timer
   b) Generate TEK FSM Stop events for all active TEK state machines
c) Disable all forwarding of SS traffic

4-B Auth Wait (Auth Reply) → Authorized

a) Clear Auth Request retry timer
b) Decrypt and record AK delivered with Auth Reply
c) Start TEK FSMs for all SAIDs listed in Authorization Reply (provided the SS supports the cryptographic suite that is associated with an SAID) and issue a TEK FSM Authorized event for each of the new TEK FSMs
d) Set the Authorization Grace timer to go off “Authorization Grace Time” seconds prior to the supplied AK’s scheduled expiration

4-D Reauth Wait (Auth Reply) → Authorized

a) Clear Auth Request retry timer
b) Decrypt and record AK delivered with Auth Reply
c) Start TEK FSMs for any newly authorized SAIDs listed in Auth Reply (provided the SS supports the cryptographic suite that is associated with the new SAID) and issue TEK FSM Authorized event for each of the new TEK FSMs
d) Generate TEK FSM Authorization Complete events for any currently active TEK FSMs whose corresponding SAIDs were listed in Auth Reply
e) Generate TEK FSM Stop events for any currently active TEK FSMs whose corresponding SAIDs were not listed in Auth Reply
f) Set the Authorization Grace timer to go off “Authorization Grace Time” seconds prior to the supplied AK’s scheduled expiration

5-B Auth Wait (Timeout) → Auth Wait

a) Send Auth Info message to BS
b) Send Auth Request message to BS
c) Set Auth Request retry timer to Auth Wait Timeout

5-D Reauth Wait (Timeout) → Reauth Wait

a) Send Auth Request message to BS
b) Set Auth Request retry timer to Reauth Wait Timeout

5-E Auth Reject Wait (Timeout) → Start

a) No protocol actions associated with state transition

6-C Authorized (Auth Grace Timeout) → Reauth Wait

a) Send Auth Request message to BS
b) Set Auth Request retry timer to Reauth Wait Timeout

7-C Authorized (Auth Invalid) → Reauth Wait

a) Clear Authorization Grace timer
b) Send Auth Request message to BS
c) Set Auth Request retry timer to Reauth Wait Timeout

d) If the Auth Invalid event is associated with a particular TEK FSM, generate a TEK FSM Authorization Pending event for the TEK state machine responsible for the Auth Invalid event (i.e., the TEK FSM that either generated the event, or sent the Key Request message the BS responded to with an Auth Invalid message)

7-D Reauth Wait (Auth Invalid) → Reauth Wait

a) If the Auth Invalid event is associated with a particular TEK FSM, generate a TEK FSM Authorization Pending event for the TEK state machine responsible for the Auth Invalid event (i.e., the TEK FSM that either generated the event, or sent the Key Request message the BS responded to with an Auth Invalid message)

8-C Authorized (Reauth) → Reauth Wait

a) Clear Authorization Grace timer
b) Send Auth Request message to BS
c) Set Auth Request retry timer to Reauth Wait Timeout

7.2.1.6 TEK state machine

The TEK state machine consists of six states and nine events (including receipt of messages) that can trigger state transitions. Like the Authorization state machine, the TEK state machine is presented in both a state flow diagram (Figure 158) and a state transition matrix (Table 203). As was the case for the Authorization state machine, the state transition matrix shall be used as the definitive specification of protocol actions associated with each state transition.

Shaded states in Figure 158 (Operational, Rekey Wait, and Rekey Reauthorize Wait) have valid keying material and encrypted traffic can be passed.

The Authorization state machine starts an independent TEK state machine for each of its authorized SAIDs.

As mentioned in 7.2.1.3, the BS maintains two active TEKs per SAID. The BS includes in its Key Replies both of these TEKs, along with their remaining lifetimes. The BS encrypts DL traffic with the older of its two TEKs and decrypts UL traffic with either the older or newer TEK, depending upon which of the two keys the SS was using at the time. The SS encrypts UL traffic with the newer of its two TEKs and decrypts DL traffic with either the older or newer TEK, depending upon which of the two keys the BS was using at the time. See 7.4 for details on SS and BS key usage requirements.

Through operation of a TEK state machine, the SS attempts to keep its copies of an SAID’s TEKs synchronized with those of its BS. A TEK state machine issues Key Requests to refresh copies of its SAID’s keying material soon after the scheduled expiration time of the older of its two TEKs and before the expiration of its newer TEK. To accommodate for SS/BS clock skew and other system processing and transmission delays, the SS schedules its Key Requests a configurable number of seconds before the newer TEK’s estimated expiration in the BS. With the receipt of the Key Reply, the SS shall always update its records with the TEK Parameters from both TEKs contained in the Key Reply message. Figure 158 illustrates the SS’s scheduling of its key refreshes in conjunction with its management of an SA’s active TEKs.

7.2.1.6.1 States

--- Start: This is the initial state of the FSM. No resources are assigned to or used by the FSM in this state—e.g., all timers are off, and no processing is scheduled.
Operational Wait (Op Wait): The TEK state machine has sent its initial request (Key Request) for its SAID’s keying material (TEK and CBC IV), and is waiting for a reply from the BS.

Operational Reauthorize Wait (Op Reauth Wait): The wait state the TEK state machine is placed in if it does not have valid keying material while the Authorization state machine is in the middle of a reauthorization cycle.

Operational: The SS has valid keying material for the associated SAID.

Rekey Wait: The TEK Refresh Timer has expired and the SS has requested a key update for this SAID. Note that the newer of its two TEKs has not expired and can still be used for both encrypting and decrypting data traffic.

Rekey Reauthorize Wait (Rekey Reauth Wait): The wait state the TEK state machine is placed in if the TEK state machine has valid traffic keying material, has an outstanding request for the latest keying material, and the Authorization state machine initiates a reauthorization cycle.

7.2.1.6.2 Messages

Note that the message formats are defined in detail in 6.3.2.3.9.

Key Request: Request a TEK for this SAID. Sent by the SS to the BS and authenticated with keyed message digest. The message authentication key is derived from the AK.

Key Reply: Response from the BS carrying the two active sets of traffic keying material for this SAID. Sent by the BS to the SS, it includes the SAID’s TEKs, encrypted with a KEK derived from
the AK. The Key Reply message is authenticated with a keyed message digest; the authentication key is derived from the AK.

— Key Reject: Response from the BS to the SS to indicate this SAID is no longer valid and no key will be sent. The Key Reject message is authenticated with a keyed message digest; the authentication key is derived from the AK.

— TEK Invalid: The BS sends an SS this message if it determines that the SS encrypted an UL PDU with an invalid TEK, i.e., an SAID’s TEK key sequence number, contained within the received PDU’s MAC header, is out of the BS’s range of known, valid sequence numbers for that SAID.

### 7.2.1.6.3 Events

— **Stop**: Sent by the Authorization FSM to an active (non-START state) TEK FSM to terminate TEK FSM and remove the corresponding SAID’s keying material from the SS’s key table. See Figure 157.

— **Authorized**: Sent by the Authorization FSM to a nonactive (START state) TEK FSM to notify TEK FSM of successful authorization. See Figure 157.

— **Authorization Pending (Auth Pend)**: Sent by the Authorization FSM to TEK FSM to place TEK FSM in a wait state while Authorization FSM completes reauthorization. See Figure 157.

— **Authorization Complete (Auth Comp)**: Sent by the Authorization FSM to a TEK FSM in the Operational Reauthorize Wait or Rekey Reauthorize Wait states to clear the wait state begun by the prior Authorization Pending event. See Figure 157.

— **TEK Invalid**: This event is triggered by either an SS’s data packet decryption logic or by the receipt of a TEK Invalid message from the BS.

An SS’s data packet decryption logic triggers a TEK Invalid event if it recognizes a loss of TEK key synchronization between itself and the encrypting BS. For example, an SAID’s TEK key sequence number, contained within the received DL MAC PDU header, is out of the SS’s range of known sequence numbers for that SAID.

A BS sends an SS a TEK Invalid message, triggering a TEK Invalid event within the SS, if the BS’s decryption logic recognizes a loss of TEK key synchronization between itself and the SS.

— **Timeout**: A retry timer timeout. Generally, the particular request is retransmitted.
— **TEK Refresh Timeout**: The TEK refresh timer timed out. This timer event signals the TEK state machine to issue a new Key Request in order to refresh its keying material. The refresh timer is set to fire a configurable duration of time (TEK Grace Time) before the expiration of the newer TEK the SS currently holds. This is configured via the BS to occur after the scheduled expiration of the older of the two TEKs.

### 7.2.1.6.4 Parameters

All configuration parameter values take the default values from Table 555 or may be specified in Auth Reply message.

— **Operational Wait Timeout**: Timeout period between sending of Key Request messages from the Op Wait state (see 11.9.18.4).
— **Rekey Wait Timeout**: Timeout period between sending of Key Request messages from the Rekey Wait state (see 11.9.18.5).
— **TEK Grace Time**: Time interval, in seconds, before the estimated expiration of a TEK that the SS starts rekeying for a new TEK. TEK Grace Time takes the default value from Table 555 or may be specified in a configuration setting within the Auth Reply message and is the same across all SAIDs (see 11.9.18.6).

### 7.2.1.6.5 Actions

Actions taken in association with state transitions are listed by `<event> (<rcvd message>) --> <state>`:

1-B  
Op Wait (*Stop*) → Start
   a) Clear Key Request retry timer
   b) Terminate TEK FSM

1-C  
Op Reauth Wait (*Stop*) → Start
   a) Terminate TEK FSM

1-D  
Operational (*Stop*) → Start
   a) Clear TEK refresh timer, which is timer set to go off “TEK Grace Time” seconds prior to the TEK’s scheduled expiration time
   b) Terminate TEK FSM
   c) Remove SAID keying material from key table

1-E  
Rekey Wait (*Stop*) → Start
   a) Clear Key Request retry timer
   b) Terminate TEK FSM
   c) Remove SAID keying material from key table
1-F  Rekey Reauth Wait \((Stop) \rightarrow \text{Start}\)
   a) Terminate TEK FSM
   b) Remove SAID keying material from key table

2-A  Start \((\text{Authorized}) \rightarrow \text{Op Wait}\)
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout

3-B  Op Wait \((\text{Auth Pend}) \rightarrow \text{Op Reauth Wait}\)
   a) Clear Key Request retry timer

3-E  Rekey Wait \((\text{Auth Pend}) \rightarrow \text{Rekey Reauth Wait}\)
   a) Clear Key Request retry timer

4-C  Op Reauth Wait \((\text{Auth Comp}) \rightarrow \text{Op Wait}\)
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout

4-F  Rekey Reauth Wait \((\text{Auth Comp}) \rightarrow \text{Rekey Wait}\)
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Rekey Wait Timeout

5-D  Operational \((\text{TEK Invalid}) \rightarrow \text{Op Wait}\)
   a) Clear TEK refresh timer
   b) Send Key Request message to BS
   c) Set Key Request retry timer to Operational Wait Timeout
   d) Remove SAID keying material from key table

5-E  Rekey Wait \((\text{TEK Invalid}) \rightarrow \text{Op Wait}\)
   a) Clear TEK refresh timer
   b) Send Key Request message to BS
   c) Set Key Request retry timer to Operational Wait Timeout
   d) Remove SAID keying material from key table

5-F  Rekey Reauth Wait \((\text{TEK Invalid}) \rightarrow \text{Op Reauth Wait}\)
   a) Remove SAID keying material from key table

6-B  Op Wait \((\text{Timeout}) \rightarrow \text{Op Wait}\)
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout
6-E   Rekey Wait (*Timeout*) → Rekey Wait
  a)   Send Key Request message to BS
  b)   Set Key Request retry timer to Rekey Wait Timeout

7-D   Operational (*TEK Refresh Timeout*) → Rekey Wait
  a)   Send Key Request message to BS
  b)   Set Key Request retry timer to Rekey Wait Timeout

8-B   Op Wait (Key Reply) → Operational
  a)   Clear Key Request retry timer
  b)   Process contents of Key Reply message and incorporate new keying material into key database
  c)   Set the TEK refresh timer to go off “TEK Grace Time” seconds prior to the key’s scheduled expiration

8-E   Rekey Wait (Key Reply) → Operational
  a)   Clear Key Request retry timer
  b)   Process contents of Key Reply message and incorporate new keying material into key database
  c)   Set the TEK refresh timer to go off “TEK Grace Time” seconds prior to the key’s scheduled expiration

9-B   Op Wait (Key Reject) → Start
  a)   Clear Key Request retry timer
  b)   Terminate TEK FSM

9-E   Rekey Wait (Key Reject) → Start
  a)   Clear Key Request retry timer
  b)   Terminate TEK FSM
  c)   Remove SAID keying material from key table

7.2.2 PKM Version 2

7.2.2.1 TEK exchange overview for PMP topology

If the SS and BS decide “No authorization” as their authorization policy, the SS and BS shall perform neither SA-TEK handshake nor Key Request/Key Reply handshake. In this case, target SAID value, which may be included in DSA-REQ/RSP messages, shall be Null SAID.

Upon achieving authorization, an SS starts a separate TEK state machine for each of the SAIDs identified in the Authorization Reply or PKMv2 SA-TEK-RSP message, if data traffic encryption is provisioned for one or more service flows. Each TEK state machine operating within the SS is responsible for managing the keying material associated with its respective SAID. TEK state machines periodically send Key Request messages to the BS, requesting a refresh of keying material for their respective SAIDs.

The BS responds to a Key Request with a Key Reply message, containing the BS’s active keying material for a specific SAID.
TEKs and KEKs may be either 64 bits or 128 bits long. SAs employing any ciphersuite with a basic block size of 128 bits shall use 128-bit TEKs and KEKs. Otherwise 64-bit TEKs and KEKs shall be used. The name TEK-64 is used to denote a 64-bit TEK and TEK-128 is used to denote a 128-bit TEK. Similarly, KEK-64 is used to denote a 64-bit KEK and KEK-128 is used to denote a 128-bit KEK.

For SAs using a ciphersuite employing DES-CBC, the TEK in the Key Reply is triple DES (3-DES) (encrypt-decrypt-encrypt or EDE mode) encrypted, using a two-key, 3-DES KEK derived from the AK.

For SAs using a ciphersuite employing 128 bits keys, such as AES-CCM mode, the TEK in the Key Reply is AES encrypted using a 128-bit key derived from the AK and a 128-bit block size.

Note that at all times the BS maintains two diversity sets of keying material per SAID. The lifetimes of the two generations overlap so that each generation becomes active halfway through the life of its predecessor and expires halfway through the life of its successor. A BS includes in its Key Replies both of an SAID’s active generations of keying material.

For SAs using a ciphersuite employing CBC mode encryption the Key Reply provides the requesting SS, in addition to the TEK and CBC IV, the remaining lifetime of each of the two sets of keying material. For SAs using a ciphersuite employing AES-CCM mode, the Key Reply provides the requesting SS, in addition to the TEK, the remaining lifetime of each of the two sets of keying material. The receiving SS uses these remaining lifetimes to estimate when the BS will invalidate a particular TEK and, therefore, when to schedule future Key Requests so that the SS requests and receives new keying material before the BS expires the keying material the SS currently holds. For AES-CCM mode, when more than half the available PN numbers in the 31-bit PN number space are exhausted, the SS shall schedule a future Key Request in the same fashion as if the key lifetime was approaching expiry. The operation of the TEK state machine’s Key Request scheduling algorithm, combined with the BS’s regimen for updating and using an SAID’s keying material (see 7.3), ensures that the SS will be able to continually exchange encrypted traffic with the BS.

A TEK state machine remains active as long as

a) The SS is authorized to operate in the BS’s security domain, i.e., it has a valid AK, and

b) The SS is authorized to participate in that particular SA, i.e., the BS continues to provide fresh keying material during rekey cycles.

The payloads of MAC PDUs sent on connections that belong to an SA that includes data encryption shall be encrypted. A MAC PDU with a payload received on such a connection with the EC bit not set shall be discarded. A MAC PDU without a payload received on such a connection shall be processed if its EC bit is set to 0, and should be discarded if its EC bit is set to 1.

### 7.2.2.2 Key derivation

The PKMv2 key hierarchy defines what keys are present in the system and how the keys are generated.

Since there are two authentication schemes, one based on RSA and one based on EAP, there are two primary sources of keying material.

The keys used to protect management message integrity and transport the TEKs are derived from source key material generated by the authentication and authorization processes. The RSA-based authorization process yields the pre-Primary AK (pre-PAK) and the EAP based authentication process yields the MSK. Keys used to protect MBS traffic are derived from the MBSAK, which is supplied by means outside the scope of this specification. These keys form the roots of the key hierarchy.

All PKMv2 key derivations are based on the Dot16KDF algorithm as defined in 7.5.4.6.1.
The MSK is the shared “master key” that is derived by the two sides in the course of executing the EAP inner method. The authentication part of the authorization flow (and the involvement of the generic EAP layer) is now complete.

7.2.2.2.1 RSA-based authorization

When the RSA-based authorization is negotiated as authorization policy, the PKMv2 RSA-Request, the PKMv2 RSA-Reply, the PKMv2 RSA-Reject, and the PKMv2 RSA-Acknowledgement messages are used to share the pre-PAK.

The pre-PAK is sent by the BS to the SS encrypted with the public key of the SS certificate. Pre-PAK is mainly used to generate the PAK. The optional EIK for transmitting authenticated EAP payload (see 7.2.2.2.2) are also generated from pre-PAK:

$$\text{EIK} | \text{PAK} = \text{Dot16KDF} (\text{pre-PAK}, \text{SS MAC Address} | \text{BSID} | \text{"EIK+PAK"}, 320)$$

PAK shall be used to generate the AK (see 7.2.2.2.3) if RSA authorization was used. PAK is 160 bits long.

7.2.2.2.2 EAP authentication

If a RSA mutual authorization took place before the EAP exchange, the EAP messages may be protected using EIK-EAP Integrity Key derived from pre-PAK (see 7.2.2.2.1). EIK is 160 bits long.

The product of the EAP exchange that is transferred to IEEE 802.16 layer is the Master Session Key (MSK), which is 512 bits in length. This key is known to the AAA server, to the Authenticator (transferred from AAA server) and to the SS. The SS and the authenticator derivate a PMK (Pairwise Master Key) by truncating the MSK to 160 bits.

The PMK derivation from the MSK during first EAP method is as follows:

$$\text{PMK} \leftarrow \text{truncate} (\text{MSK}, 160)$$

After the successful initial authentication, the SS shall initiate reauthentication prior to expiration of PMK lifetime by sending the PKMv2 EAP Start message signed by H/CMAC_KEY_U derived from the AK. Either the BS or SS may initiate reauthentication at any time prior to expiration of PMK lifetime. After expiration of the PMK lifetime, authentication shall be performed using initial authentication procedures.

7.2.2.2.3 AK derivation

The BS and the SS will share the AK which is derived from the PMK (from EAP-based authorization procedure) and/or the PAK (from RSA-based authorization procedure). Note that PAK and/or PMK can be used according to the value of Authorization Policy Support field included in the SBC-REQ/RSP messages.

After the authorization procedure has been performed, the MS and BS will both possess the PAK.

After the EAP based authentication procedure, the MS and the Authenticator will both possess the PMK.

If both the authorization and EAP based authentication procedure were performed, the MS and the Authenticator will possess both the PAK and PMK. The derivation of the AK varies based on which keys are possessed.
The AK shall be generated as follows:

If (PAK and PMK)
    AK ← Dot16KDF (PAK ∘ PMK, SS MAC Address | BSID | PAK | “AK”, 160)
Else
    If (PAK)
        AK ← Dot16KDF (PAK, SS MAC Address | BSID | PAK | “AK”, 160)
    Else // PMK only
        AK ← Dot16KDF(PMK, SS MAC Address | BSID | “AK”, 160);
    Endif
Endif

7.2.2.2.4 KEK derivation

The KEK is derived directly from the AK. The KEK is defined in 7.2.2.2.9. It is used to encrypt the TEKs, GKEK and all other keys sent by the BS to SS in unicast message.

7.2.2.2.5 GKEK derivation

GKEK is randomly generated at the BS or a network entity (for example, an ASA server) and transmitted to the SS encrypted with the KEK. There is one GKEK per Group Security Association. GKEK is used to encrypt the GTEKs sent by the BS to the SSs in the same multicast group or MBS group.

7.2.2.2.6 Traffic encryption key (TEK)

The TEK is generated as a random number in the BS and is encrypted using the corresponding TEK encryption algorithm (e.g., AES key wrap for SAs with TEK encryption algorithm identifier in the cryptographic suite is equal to 0x04), keyed with the KEK and transferred between BS and SS in the TEK exchange.

7.2.2.2.6.1 Counter-based TEK Generation for HO

When both sides (MS and BS) indicate support for Seamless Handover, the TEKs, during handover, shall be generated by the BS and MS respectively using the following formula:

TEKi = Dot16KDF (KEK_prime, CMAC_KEY_COUNT_T | SAID | “TEKi Generation”, 128)

In the above formula, KEK_prime is a simple transformation of KEK in order to cryptographically isolate the KEK used for encrypting the TEK (legacy) from KEK’ used for generating the TEKs during HO. KEK’ is computed as follows: KEK_prime = Dot16KDF(KEK, “KEK for TEK Generation”, 128).

The generated TEKs shall not be transferred between the BS and MS.

In the above equation, CMAC_KEY_COUNT_T (CMAC_KEY_COUNT for Traffic) is defined as follows: After the exchange of RNG-REQ and RNG-RSP messages that is used to establish a value for the CMAC_KEY_COUNT at the MS and the BS, CMAC_KEY_COUNT_T = CMAC_KEY_COUNT. During handover before the exchange of RNG-REQ and RNG-RSP messages, CMAC_KEY_COUNT_T_M = CMAC_KEY_COUNT_M + 1 and CMAC_KEY_COUNT_T_B = CMAC_KEY_COUNT_B, where CMAC_KEY_COUNT_T_M and CMAC_KEY_COUNT_T_B are the values of CMAC_KEY_COUNT_T at the MS and the BS respectively.

Both the MS and the BS shall compute the TEKs based on the current values of CMAC_KEY_COUNT_T. Initially, TEK0 and TEK1 Lifetimes are updated based on the value of the “TEK Lifetime” parameter sent to the MS in BSHO-REQ/RSP during handover preparation. More specifically, the lifetime of TEK0 is set to
“TEK Lifetime”/2 and the lifetime of TEK1 is set to “TEK_Lifetime.” PN0, PN1, RxPN0, and RxPN1 shall be initialized to 0.

During handover, before any transmission of data between the MS and the target BS, the MS shall set CMAC_KEY_COUNT_T_M = CMAC_KEY_COUNT_M + 1 and the target BS shall set CMAC_KEY_COUNT_T_B = CMAC_KEY_COUNT_N. Unless the MS has cached a TEK context associated with the target BS and the current value of CMAC_KEY_COUNT_T_M, the MS shall generate new values for the TEKs using the above formula. Unless the target BS has cached a TEK context associated with the MS and the current value of CMAC_KEY_COUNT_T_B, the BS shall generate new values for the TEKs using the above formula. Otherwise the MS and BS shall apply the TEKs and associated parameters, including PN windows, from the cached contexts.

Occasionally, CMAC_KEY_COUNT_T_M and CMAC_KEY_COUNT_T_B are not equal, in which case the generated TEKs will be different too. In such cases, the target BS may attempt self-synchronizing the value of CMAC_KEY_COUNT_T_B by increasing the value until it can properly decode UL traffic.

If the target BS receives a valid RNG-REQ message including a CMAC_KEY_COUNT TLV (see 7.2.2.2.9.1) from the MS, and the received CMAC_KEY_COUNT value is different from CMAC_KEY_COUNT_T_B, it shall set CMAC_KEY_COUNT_T_B to the received CMAC_KEY_COUNT value and regenerate new values for the TEKs using the above formula.

If the handover is not completed at the target BS, the target BS shall cache the TEK context until it can determine that CMAC_KEY_COUNTN has been incremented (e.g., by receiving a backbone message from the Authenticator). Likewise, the MS shall cache the TEK context until it increments CMAC_KEY_COUNTM. See 7.2.2.2.9.1 for further details on CMAC_KEY_COUNT handling.

7.2.2.2.7 Group traffic encryption key (GTEK)

The GTEK is used to encrypt data packets of the multicast service or the MBS and it is shared among all SSs that belong to the multicast group or the MBS group. There are two GTEKs per GSA.

The GTEK is randomly generated at the BS or at certain network node and is encrypted using same algorithms applied to encryption for TEK and transmitted to the SS in broadcast or unicast messages. The GTEK in a PKMv2 Key-Reply message shall be encrypted by the KEK. Also, the GTEK in a PKMv2 Group Key Update Command message shall be encrypted by the GKEK.

7.2.2.2.8 MBS traffic key (MTK)

The generation and transport of the MAK (MBS AK) is outside the scope of the IEEE 802.16 standard. It is provided through means defined at higher layers. However, the key such as the MTK is used in the link cipher; therefore, its existence needs to be defined in layer 2.

The MTK is used to encrypt the MBS traffic data. It is defined as follows:

\[ MTK \leftarrow \text{Dot16KDF} (\text{MAK}, \text{MGTEK} \mid \text{“MTK”}, 128) \]

The MGTEK is the GTEK for the MBS. An SS can get the GTEK by exchanging the PKMv2 Key Request message and the PKMv2 Key Reply message with a BS or by receiving the PKMv2 Group-Key-Update-Command message from a BS. The generation and transport of the GTEK is defined as in 6.3.2.3.9 and 7.9.
7.2.2.2.9 Message authentication keys (HMAC/CMAC) and KEK derivation

7.2.2.2.9.1 CMAC_KEY_COUNT management

The MS shall maintain a CMAC_KEY_COUNT counter for each PMK context, and the Authenticator is assumed to maintain a CMAC_KEY_COUNT counter for each PMK context, which is normally kept synchronized with the corresponding counter at the MS.

The value of this counter maintained by the MS is denoted as CMAC_KEY_COUNT_M and the value maintained by the Authenticator is denoted as CMAC_KEY_COUNT_N. Each AK context that a BS maintains has a CMAC_KEY_COUNT value, which is denoted CMAC_KEY_COUNT_B.

7.2.2.2.9.1.1 Maintenance of CMAC_KEY_COUNT_M by the MS

Upon successful completion of the PKMv2 Authentication or Re-authentication, and establishment of a new PMK, the MS shall instantiate a new CMAC_KEY_COUNT counter and set its value to zero. In particular, this shall occur upon reception of the SA TEK Challenge message. The MS shall initiate re-authentication before the CMAC_KEY_COUNT_M reaches its maximum value of 65535. The MS shall manage a separate CMAC_KEY_COUNT_M counter for every active PMK context. Specifically, during re-authentication, after EAP completion, but before the activation of the new AK, the old CMAC_KEY_COUNT_M (corresponding to the old PMK) shall be used for CMAC generation of MAC control messages, while the new CMAC_KEY_COUNT_M shall be used for CMAC generation for PKMv2 3-way handshake messages.

7.2.2.2.9.1.1.1 CMAC_KEY_LOCK state

When the MS decides to reenter the network or perform Secure Location Update (immediately prior to transmitting a RNG-REQ for re-entry or Secure Location Update to a first preferred BS), or handover to a target BS (immediately prior to transmitting RNG-REQ for handover to a first target BS), the MS shall perform the following steps in the stated order:

1) If the MS is handing over to a target BS, it shall cache the current values of CMAC_KEY_ _Serving BS and CMAC_PN_ _Serving BS used at the serving BS.
2) The MS shall increment the CMAC_KEY_COUNT_M counter.
3) The MS shall enter the CMAC_Key_Lock state.

For each BS to which it sends a RNG-REQ message for the first time while in the CMAC_Key_Lock state, the MS shall re-compute new values of CMAC_KEY_ _Preferred BS/Target BS based on the CMAC_KEY_COUNT_M value and reset the CMAC_PN_ _Preferred BS/Target BS counter values to zero.

While in the CMAC_Key_Lock state, the MS shall cache the values of the CMAC_PN_ _Preferred BS/Target BS counters and CMAC_KEY_ _Preferred BS/Target BS corresponding to each preferred or target BS to which it has sent an RNG REQ message. The MS shall update and use these cached values for any subsequent message exchange with the same target or preferred BS while in the CMAC_Key_Lock state.

When the MS has completed network reentry at a preferred BS or has completed handover to a target BS (in either case establishing the preferred BS or target BS as the new serving BS) or the MS has completed Secure Location Update, or the MS cancels handover and remains connected to its current serving BS, the MS shall exit the CMAC_Key_Lock state.

Upon exit of the CMAC_Key_Lock state, the MS may purge the cached values of CMAC_PN_ _ and CMAC_KEY* for all BSs other than the serving BS.
7.2.2.2.9.1.2 Processing of CMAC_KEY_COUNTB by the BS

The BS may possess one or more AK contexts associated with the MS, each of which includes the value of CMAC_KEY_COUNTB. This value shall be maintained as specified in subsequent paragraphs of this subclause.

Upon successful completion of the PKMv2 Authentication or Re-authentication, and establishment of a new AK context, the BS shall set CMAC_KEY_COUNTB of the corresponding newly instantiated AK context to zero. In particular, this shall occur immediately prior to the transmission of the SA TEK Challenge message. The BS shall manage a separate CMAC_KEY_COUNTB for every AK context it is maintaining. Specifically, during re-authentication, after EAP completion, but before the activation of the new AK, the old CMAC_KEY_COUNTB (corresponding to the old AK context) shall be used for CMAC generation of MAC control messages, while the new CMAC_KEY_COUNTB shall be used for CMAC generation for PKMv2 3-way handshake messages.

Upon receiving the RNG-REQ message from the MS containing the CMAC_KEY_COUNT TLV, the BS shall compare the received CMAC_KEY_COUNT value, which is CMAC_KEY_COUNTM, with CMAC_KEY_COUNTB. If the BS has no AK context for the MS corresponding to the AK of the CMAC tuple TLV in the received RNG-REQ message it shall create an AK context and set the CMAC_KEY_COUNTB to CMAC_KEY_COUNTM (i.e., the value of CMAC_KEY_COUNT counter maintained by the Authenticator for the corresponding PMK context).

If CMAC_KEY_COUNTM < CMAC_KEY_COUNTB, the BS shall process the message as having an invalid CMAC tuple and send a RNG-RSP message requesting re-authentication; see subclauses 6.3.23.8.2.1 and 6.3.21.2.7.

If CMAC_KEY_COUNTB < CMAC_KEY_COUNTM, the BS shall cache the state of the AK context, generate the CMAC_KEY_* using CMAC_KEY_COUNTM, set CMAC_PN_* to zero, and validate the received RNG-REQ message. If it is valid, the BS may purge the cached state, and shall set CMAC_KEY_COUNTB = CMAC_KEY_COUNTM, update the AK context and send a RNG-RSP message to the MS including a CMAC tuple TLV. The BS shall cache the AK context in case it receives subsequent MAC management messages from the MS. When the BS can determine that the MS has exited the CMAC_K eck state associated with CMAC_KEY_COUNTM and if it is not serving the MS, it may purge the cached AK context. If the CMAC value is not valid, the BS shall send a RNG-RSP message requesting re-authentication; refer to subclauses 6.3.23.8.2.1 and 6.3.21.2.7.

If CMAC_KEY_COUNTB = CMAC_KEY_COUNTM, the BS shall validate the received RNG-REQ using the cached AK context. If the CMAC value is valid, the BS shall send the RNG-RSP message to the MS allowing legitimate entry. If the CMAC value is invalid, the BS shall send a RNG-RSP message requesting re-authentication; refer to subclauses 6.3.23.8.2.1 and 6.3.21.2.7.

Once the MS has completed network re-entry, cancelled handover, or completed Secure Location Update, the BS is assumed to inform the Authenticator and send to it the value of CMAC_KEY_COUNTM.

7.2.2.2.9.2 Derivation of message authentication codes

Message authentication code keys are used to sign management messages in order to validate the authenticity of these messages. The message authentication code to be used is negotiated at SS Basic Capabilities negotiation.

There is a different key for UL and DL messages. Also, a different message authentication key is generated for a broadcast message (this is DL direction only) and for a unicast message.
In general, the message authentication keys used to generate the CMAC value and the HMAC-Digest are derived from the AK.

An alternative method of CMAC key generation, namely CMAC-0, may be used in the limited mobility environments as described in Annex I.

The keys used for CMAC key and for KEK are as follows:

\[
\begin{align*}
\text{CMAC\_PREKEY\_U} &\ | \text{CMAC\_PREKEY\_D} | \text{KEK} \leftarrow \text{Dot16KDF}(\text{AK, SS MAC Address | BSID | “CMAC\_KEYS+KEK”, 384}) \\
\text{CMAC\_KEY\_GD} &\leftarrow \text{Dot16KDF}(\text{GKEK, “GROUP CMAC KEY”, 128}) \text{ (Used for broadcast MAC message such as a PKMv2 Group-Key-Update-Command message)}
\end{align*}
\]

\[
\begin{align*}
\text{CMAC\_KEY\_U} &\leftarrow \text{AES}\_\text{CMAC}\_\text{PREKEY}\_U(\text{CMAC\_KEY\_COUNT}) \\
\text{CMAC\_KEY\_D} &\leftarrow \text{AES}\_\text{CMAC}\_\text{PREKEY}\_D(\text{CMAC\_KEY\_COUNT})
\end{align*}
\]

For a fixed SS, the CMAC\_KEY\_COUNT shall be set to 0 in the derivation of the CMAC\_KEY\_U and CMAC\_KEY\_D at the BS and the SS.

Specifically, the preprocessed value of CMAC\_PREKEY\_* is treated as the Cipher Key of the Advanced Encryption Standard (AES) algorithm AES128 (FIPS197). The CMAC\_KEY\_COUNT is treated as the Input Block Plain Text of this algorithm. The AES128 algorithm is executed once. The Output Block Cipher Text of this algorithm is treated as the resulting CMAC\_KEY\_* . When CMAC\_KEY\_COUNT is used as an input of AES128 algorithm, 112 zero bits are prepadded before the 16-bit CMAC\_KEY\_COUNT where the CMAC\_KEY\_COUNT is regarded as most-significant-bit first order. The AES input is also defined as most-significant-bit first order.

The keys used for HMAC key and for KEK are as follows:

\[
\begin{align*}
\text{HMAC\_KEY\_U} &\ | \text{HMAC\_KEY\_D} | \text{KEK} \leftarrow \text{Dot16KDF}(\text{AK, SS MAC Address | BSID | “HMAC\_KEYS+KEK”, 448}) \\
\text{HMAC\_KEY\_GD} &\leftarrow \text{Dot16KDF}(\text{GKEK, “GROUP HMAC KEY”, 160}) \text{ (Used for broadcast MAC message such as a PKMv2 Group-Key-Update-Command message)}
\end{align*}
\]

Exceptionally, the message authentication keys for the HMAC/CMAC Digest included in a PKMv2 Authenticated-EAP-Transfer message are derived from the EIK instead of the AK.

The keys used for CMAC key and for KEK are as follows:

\[
\begin{align*}
\text{CMAC\_KEY\_U} &\ | \text{CMAC\_KEY\_D} \leftarrow \text{Dot16KDF}(\text{EIK, SS MAC Address | BSID | “CMAC\_KEYS”, 256})
\end{align*}
\]

The keys used for HMAC key and for KEK are as follows:

\[
\begin{align*}
\text{HMAC\_KEY\_U} &\ | \text{HMAC\_KEY\_D} \leftarrow \text{Dot16KDF}(\text{EIK, SS MAC Address | BSID | “HMAC\_KEYS”, 320})
\end{align*}
\]
7.2.2.2.10 Key hierarchy

Figure 159 outlines the process to calculate the AK when the RSA-based authorization process has taken place, but where the EAP based authentication process has not taken place, or the EAP method used has not yielded an MSK.

![Diagram of key hierarchy](image)

**Figure 159—AK from PAK only (from RSA-based authorization)**
Figure 160 outlines the process to calculate the AK when both the RSA-based authorization exchange has taken place, yielding a PAK and the EAP based authentication exchange has taken place, yielding an MSK.

![Figure 160—AK from PAK and PMK (RSA-based and EAP-based authorization)](image)

Figure 161 outlines the process to calculate the AK when only the EAP based authentication exchange has taken place, yielding an MSK.

**Figure 162—HMAC/CMAC/KEK derivation from AK**

Figure 163 outlines the MBS key hierarchies starting from the MAK.

![Diagram](image2)

**Figure 163—MTK key derivation from MAK**
7.2.2.2.11 Maintenance of PMK and AK

The BS and SS maintain cached PMK and AK as follows:

a) **PMK caching.** An SS caches a PMK upon successful EAP authentication. An Authenticator caches a PMK upon its receipt via the AAA protocol. Upon caching a new PMK for a particular SS, an Authenticator shall delete any PMK for that SS (as well as all associated AKs).

For the case of reauthentication, deletion of old PMKs at Authenticator and SS is accomplished via the switchover mechanism described in this subclause using the messages in 6.3.2.3.9.20.

The Authenticator and SS will additionally delete PMKs and/or associated AKs in various situations—including lifetime expiration, reauthentication, and reclamation of memory resources, or as the result of other mechanisms beyond the scope of this specification.

In the case of reauthentication, the older PMK and its AKs shall be deleted by the SS and the BS after successful completion of the 3-way SA-TEK handshake (7.8.1).

b) **AK activation and deactivation.** Successful completion of the 3-way SA-TEK handshake causes the activation of every AK associated with the new PMK and any BS under the current Authenticator (i.e., when the MS hands over or re-enters a target BS, and the 3-way SA-TEK handshake associated with the current PMK has completed successfully at some BS under the target BS’s Authenticator, the AK associated with the current PMK and the target BS is used without a new 3-way SA-TEK handshake at the target BS).

If the packet counter belonging to a short HMAC or a CMAC key reaches its maximum value, the associated AK becomes permanently deactivated.

The BS and SS shall maintain the AK context (i.e., replay counters etc.) as long as they retain the AK.

c) **Legacy mobiles.** To handle legacy mobiles and base stations that were developed in accordance with IEEE Std 802.16e-2005/Cor1, a compatible but not for standard implementation solution is presented in Annex I.

7.2.2.2.12 PKMv2 PMK and AK switching methods

Once the PKMv2 SA-TEK 3-way handshake begins, the BS and SS shall use the new AK matching the new PMK context for the 3-way handshake messages. Other messages shall continue to use the old AK until the 3-way handshake completes successfully. Upon successful completion of the 3-way handshake, all messages shall use the new AK.

The old AK matching the old PMK context may be used for receiving packets before the “frame number” attribute specified in PKMv2 SA-TEK-response message.

7.2.2.3 Associations

Keying material is held within associations. There are three types of association: The security associations (SA) that maintain keying material for unicast connections; group security associations (GSAs) that hold keying material for multicast groups; and multicast and broadcast service group security associations (MBSGSAs) that hold keying material for MBSs.

If SS and BS decide “No authorization” as their authorization policy, they do not have any security association. In this case, Null SAID shall be used as the target SAID field in DSA-REQ/RSP messages.

If authorization is performed but the MS and BS decide to create an unprotected SF, the Null SAID may be used as the target SAID field in DSA-REQ/RSP messages.
7.2.2.3.1 Security associations (SAs)

A SA contains keying material that is used to protect unicast connections. The contents of an SA are as follows:

- The SAID, a 16-bit identifier for the SA. The SAID shall be unique within a BS.
- The KEK, a 128-bit key encryption key, derived from the AK.
- TEK0 and TEK1, 128-bit traffic encryption keys, generated within the BS and transferred from the BS to the SS using a secure key exchange.
- The TEK Lifetimes TEK0 and TEK1, a key aging lifetime value.
- PN0 and PN1, 32-bit packet numbers for use by the link cipher.
- RxPN0 and RxPN1, 32-bit receive sequence counter, for use by the link cipher.

A security association is shared between an SS and a BS or, in case of ongoing MDHO(FBSS) between MS and BSs from Diversity Set.

7.2.2.3.2 Group security associations (GSAs)

The GSA contains keying material used to secure multicast groups. These are defined separately from SAs since GSA offer a lower security bound than unicast security associations, since keying material is shared between all members of the group, allowing any member of the group to forge traffic as if it came from any other member of the group.

The contents of a GSA are as follows:

- The GKEK, which serves the same function as an SA KEK but for a GSA.
- The GTEK, which served the same function as an SA TEK but for a GSA.

7.2.2.3.3 Multicast and broadcast service group security associations (MBSGSAs)

The primary keying material in the MBSGSA is the MAK. The MAK is provisioned by an external entity, such as an MBS server. The MAK may be common among members of an MBS group.

The contents of an MBSGSA are as follows:

- The MAK, a 160-bit MBS AK, serves the same function as the AK but local to the MBSGSA.
- The MGTEK, a 128-bit MBS GTEK, used indirectly to protect MBS traffic. It is updated more frequently than the MAK.
- The MTK (MBS Traffic Key) a 128-bit key used to protect MBS traffic, derived from the MAK and MGTEK.

The MGTEK is a random number provisioned by the access network such as a BS as an access network AK. It is only used for generating MTK together with MAK.

In an MBSGSA, the usage of MGTEK is same as that of GTEK.

Key encryption algorithm and key transport mechanism of GTEK shall be also applied for MGTEK.

7.2.2.4 Security context

The security context is a set of parameters linked to a key in each hierarchy that defines the scope while the key usage is considered to be secure.
Examples of these parameters are key lifetime and counters ensuring the same encryption will not be used more than once. When the context of the key expires, a new key should be obtained to continue working.

The purpose of this subclause is to define the context that belongs to each key, how it is obtained and the scope of its usage.

### 7.2.2.4.1 AK context

The PMK key has two phases of lifetime: the first begins at PMK creation and the second begins after validation by the 3-way handshake.

The phases ensure that when the PMK is created it will be defined with the PMK or PAK pre-handshake lifetime and after successful 3-way handshake, this lifetime may be enlarged using the PMK lifetime TLV within the 3-way handshake.

For the HMAC and short-HMAC modes, if the cached AK and associated context is lost by either BS or SS, no new AKs can be derived from this PMK on HO.

Cached AKs that were derived from the PMK can continue to be used in HO.

Reauthentication is required to obtain a new PMK so new AKs can be derived.

The AK context is described in Table 204.

</tbody>
</table>
7.2.2.4.2 GKEK context

The GKEK is the head of the group key hierarchy. There is a separate GKEK for each group (each GSA). This key is randomly generated by the BS and transferred to the SS encrypted with KEK. It is used to encrypt group TEKs (GTEK) when broadcasting them to all SSs. The GKEK context is described in Table 205.

Table 205—GKEK Context

<td>The sequence number of the GKEK. The new GKEK sequence number shall be one greater than the preceding GKEK sequence number</td>
</tr>
</tbody>
</table>

GKEK or KEK can be used for encrypting MGTEK for MBS GSA.

7.2.2.4.3 PMK context

The PMK context includes all parameters associated with the PMK. This context is created when EAP Authentication completes.
The PMK context is described in Table 206.

### Table 206—PMK context

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

#### 7.2.2.5 Authentication state machine

The Authentication state machine for single EAP authentication consists of six states and sixteen events (including receipt of messages and events from other FSMs) that may trigger state transitions. The Authentication state machine is presented in both a state flow diagram (Figure 164) and a state transition matrix (Table 208). The state transition matrix shall be used as the definitive specification of protocol actions associated with each state transition.

The Authentication process has two phases: EAP phase and 3-way handshake phase (also known as SA_TEK exchange).

The EAP phase is controlled by the EAP_FSM as defined in IETF RFC3748 and IETF RFC4173 and it is out of scope in this standard.
The Auth_FSM is responsible for all PKM phase but the actual EAP exchange and communicates with other FSMs in the system using events.

The relationships between the security related FSMs in the system are as described in the Figure 164.

Through operation of an Authentication state machine, the MS attempts to get authenticated with the NW, maintain this authentication and support Authentication context switching for HO and Idle situations. The state machine takes care of getting authenticated with the NW, ensuring re-authentication will occur before authentication expires and support key derivations according to support optimized re-entry for HO and idle.

The optimized re-entry support is done in a special state in which the NW connection is suspended and therefore re-authentication cannot occur, the triggers for re-authentication continue to work in this state but the initiation is done only after returning to an authenticated state.

### 7.2.2.5.1 States

*Stopped:* This is the initial state of the FSM. Nothing is done in this state.
Not Authenticated: The Authorization FSM is not authenticated and waiting for an MSK from the EAP FSM to perform 3-way handshake. The FSM also waits for a PKMv2 SA-TEK-Challenge message in this state. Upon receiving a PKMv2 SA-TEK-Challenge message, the MS validates H/CMAC Digest using H/CMAC_KEY_D. Any PKMv2 SA-TEK-Challenge messages with invalid H/CMAC Digest or without H/CMAC Digest are discarded.

SA-TEK-Response Wait: The Authorization FSM has sent a PKMv2 SA-TEK-Request and waits for a PKMv2 SA-TEK-Response message in this state. If it does not receive a PKMv2 SA-TEK-Response message within SATEK Timer, the MS may resend the message up to SATEKRequestMaxResends times. Upon receiving a PKMv2 SA-TEK-Challenge message, the MS resends a PKMv2 SA-TEK-Request message. Any PKMv2 SA-TEK-Challenge or SA-TEK-Response messages with invalid H/CMAC Digest or without H/CMAC Digest are discarded.

Authenticated: The MS has successfully completed EAP-based authentication and has valid PMK context and AK context derived from the MSK from the EAP FSM. Transition from SA-TEK-Response Wait into this state triggers the creation of TEK FSMs.

If the MS has a valid AK context, all the management messages with Basic CID or Primary Management CID should be sent with H/CMAC Digest/Tuple. It should be discarded if the message does not have a valid H/CMAC Digest/Tuple. In this state the MS may hold two AK contexts: the old AK context and the new AK context which is created during re-authentication. The old AK context is deleted in the frame number specified in the PKMv2 SA-TEK-Response message. In addition, the Authorization FSM also waits for a PKMv2 SA-TEK-Challenge message in this state before the AK expires.

Reauth SA-TEK-Response Wait: The Authorization FSM has sent a PKMv2 SA-TEK-Request message for re-authentication and waits for a PKMv2 SA-TEK-Response message. If it does not receive a PKMv2 SA-TEK-Response message within SATEK Timer, the MS may resend the message up to SATEKRequestMaxResends times.

In this state there are two AK contexts: the old AK context for the management messages which need H/CMAC-Tuple and new AK context for 3-way handshake messages during re-authentication. The new AK context is created as soon as EAP phase is completed. After the completion of the 3-way handshake, the new AK context should be used.

Reentry Authentication Wait: In this state the Authorization FSM has the AK context of the target BS. The MS should have the AK context of the target BS in this state before it sends a RNG-REQ message with H/CMAC Tuple during HO or reentry. During HO or reentry, the Authorization FSM is in this state when the MS sends a RNG-REQ message. The state of Authorization FSM changes when the MS receives a RNG-RSP message. The next state depends on the value of HO Process Optimization TLV included in the received RNG-RSP message. If HO Process Optimization Bit 1 set to zero, meaning the PKM Authentication phase is not omitted, the Authorization FSM receives Start Authentication event which triggers to stop all the TEK FSMs, re-initialize the Authorization FSM and change the state to Not Authenticated. The TLVs included in the RNG-RSP message also affects the next state. If HO Process Optimization Bit 1 and Bit 2 set to one and zero respectively and the SA-TEK-Update TLV is included in the RNG-RSP, the FSM receives Reentry Completed event. The state of the Authorization FSM changes to Authenticated when the Reentry Completed event is issued.

7.2.2.5.2 Messages

PKMv2 SA-TEK-Challenge: The first message of 3-way handshake. It is sent from the BS to the MS after EAP-based authentication has finished and it is protected by H/CMAC-Digest using H/CMAC_KEY_D of the last EAP-based authentication.
PKMv2 SA-TEK-Request: The second message of 3-way handshake. It is sent from the MS to the BS as a response to a PKMv2 SA-TEK-Challenge message, protected by CMAC-Digest using H/CMAC_KEY_U of the last EAP-based authentication.

PKMv2 SA-TEK-Response: The last message of 3-way handshake. It is sent from the BS to the MS as a response to a PKMv2 SA-TEK-Request message and it is protected by CMAC-Digest using H/CMAC_KEY_D of the last EAP-based authentication.

PKMv2 EAP Start: The message used by the MS to initiate EAP-based re-authentication. If the BS does not respond with PKMv2 EAP Transfer messages, the MS resends it to start re-authentication.

PKMv2 EAP Transfer: This message is bidirectional and used for transmission of EAP packet. This message is sent unprotected in “Not Authenticated” state. In Authenticated state, H/CMAC Digest and Key Sequence Number attributes shall be included in the message.

7.2.2.5.3 Events

Start Authentication: After completion of basic capabilities negotiation, this event is generated to start the Authentication state machine. It is also issued when the HO Process Optimization Bit 1 of the RNG-RSP message is set to zero during HO or network reentry.

EAP Success: EAP FSM generates this event to notify the Authorization FSM that EAP protocol has been completed successfully.

SATEK Timeout: This event is generated when the MS does not receive PKMv2 SA-TEK-Response message from the BS within SATEK Timer after transmitting a PKMv2 SA-TEK-Request message. The MS may resend the PKMv2 SA-TEK-Request up to SATEKRequestMaxResends times.

SATEK request max resends elapsed: The Authorization state machine generates this event when the MS has transmitted the PKMv2 SA-TEK-Request message up to SATEKRequestMaxResends times and SATEK Timer expires.

Re-authentication Needed: An internal event to trigger re-authentication. This event can be derived from several sources such as Authorization Grace Timeout or other reason that makes authentication close to expiration.

Start Reentry: An event to inform the Authorization FSM that MS is in reentry phase. The FSM should derive the new AK context for the target BS.

EAPStart Timeout: A timer event that causes the MS to resend a PKMv2 EAP-Start message in order to ask the BS to start EAP-based re-authentication. This event is used in the case Authorization FSM receives neither the EAP Failure event nor the EAP Success event after transmitting the PKMv2 EAP Start message. This timer is active only after Re-authentication Needed event occurred.

Reentry Completed: An event to notify the Authorization FSM that reentry has finished successfully. This event is issued when the MS receives a RNG-RSP message including HO Process Optimization Bit 1 and Bit 2 set to one and zero respectively and SA-TEK-Update TLV during HO or network re-entry from idle mode. This event is also issued when the MS receives a RNG-RSP message including HO Process Optimization Bit 1 and Bit 2 both set to one during HO.

HO Canceled: An event to notify the Authorization FSM that HO was canceled. The cached AK context for the serving BS should be retrieved.
**TBS (Target BS) changed**: An Event to notify the Authorization FSM that it needs to generate the AK context for the new target BS.

**Authentication Expired**: This event indicates the AK context became obsolete due to the expiration of AK lifetime.

**EAP Failure**: This event indicates EAP-based authentication has failed.

**External Stop**: The event to stop the Authorization FSM and terminate connection with BS.

NOTE—The following events are sent by an Authorization state machine to the TEK state machine:

- **[TEK] Stop**: Sent by the Authorization FSM to an active (non-START state) TEK FSM to terminate the FSM and remove the corresponding SAID’s keying material from the SS’s key table.
- **[TEK] Authorized**: Sent by the Authorization FSM to a nonactive (START state), but valid TEK FSM.
- **[TEK] Authorization Pending (Auth Pend)**: Sent by the Authorization FSM to a specific TEK FSM to place that TEK FSM in a wait state until the Authorization FSM can complete its reauthorization operation. This event shall be sent to the TEK FSM in the Operational Wait (Op Wait) or Rekey Wait states when Authorization FSM starts re-authentication.
- **[TEK] Authorization Complete (Auth Comp)**: Sent by the Authorization FSM to a TEK FSM in the Operational Reauthorize Wait (Op Reauth Wait) or Rekey Reauthorize Wait (Rekey Reauth Wait) states to clear the wait state begun by a TEK FSM Authorization Pending event. This event shall be sent to the TEK FSM in the Operational Reauthorize Wait or Rekey Reauthorize Wait states when Authorization FSM ends re-authentication.

### 7.2.2.5.4 Parameters

**SATEK Timer**: The timer which expires if the MS does not receive a PKMv2 SA-TEK-Response message after sending a PKMv2 SA-TEK-Request message.

**EAPStart Timeout**: Timeout period between sending PKMv2 EAP Start messages from Authenticated state.

**Authorization Grace Time**: Amount of time before the AK is scheduled to expire in order that the MS may start re-authentication before the authentication expiry.

### 7.2.2.5.5 Actions

1-A: Stopped (Start Auth) → Not Authenticated
   a) Enable PKMv2 EAP-Transfer messages to be transferred.

1-F: Reentry Authentication Wait (Start Auth) → Not Authenticated
   a) Stop TEK FSMs
   b) Re-initialize the Authorization FSM
   c) Enable PKMv2 EAP-Transfer messages to be transferred.

2-B: Not Authenticated (PKMv2 SA-TEK-Challenge) → SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message.
   b) Start SATEK Timer.

2-C: SA-TEK-Response Wait (PKMv2 SA-TEK-Challenge) → SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message.
   b) Start SATEK Timer.

2-D: Authenticated (PKMv2 SA-TEK-Challenge) → Reauth SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message.
   b) Start SATEK Timer.
2-E: Reauth SA-TEK-Response Wait (PKMv2 SA-TEK-Challenge) → Reauth SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message.
   b) Start SATEK Timer.

3-C: SA-TEK-Response Wait (PKMv2 SA-TEK-Response) → Authenticated
   a) Stop SATEK Timer
   b) Start TEK FSMs
   c) Start Authorization Grace Timer

3-E: Reauth SA-TEK-Response Wait (PKMv2 SA-TEK-Response) → Authenticated
   a) Stop SATEK Timer
   b) Start Authorization Grace Timer
   c) Set the frame number for old AK context to be invalid.

4-B: Not Authenticated (EAP Success) → Not Authenticated
   a) Obtain the MSK
   b) Derive the keys derived from the PMK

4-D: Authenticated (EAP Success) → Authenticated
   a) Obtain the new MSK
   b) Derive the keys derived from the PMK

5-C: SA-TEK-Response Wait (SATEK Timeout) → SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message
   b) Start SATEK Timer

5-E: Reauth SA-TEK-Response Wait (SATEK Timeout) → Reauth SA-TEK-Response Wait
   a) Send a PKMv2 SA-TEK-Request message
   b) Start SATEK Timer

6-C: SA-TEK-Response Wait (SATEK request max resend elapsed) → Stopped
   a) Stop the Authorization FSM

6-E: Reauth SA-TEK-Response Wait (SATEK request max resend elapsed) → Stopped
   a) Stop TEK FSMs
   b) Stop the Authorization FSM

7-D: Authenticated (Re-authentication Needed) → Authenticated
   a) Send a PKMv2 EAP-Start message
   b) Start EAPStart Timer

8-D: Authenticated (Start Reentry) → Reentry Authentication Wait
   a) Generate the AK context for the target BS

8-E: Reauth SA-TEK-Response Wait (Start Reentry) → Reentry Authentication Wait
   a) Remove the new AK context for the serving BS generated during performing EAP-based re-authentication procedure
   b) Generate the AK contexts for the target BS generated from old PMK context and new PMK context

9-D: Authenticated (EAPStart Timeout) → Authenticated
   a) Send a PKMv2 EAP-Start message
   b) Start EAPStart Timer
10-F: Reentry Authentication Wait (HO Canceled) → Authenticated
   a) Remove the AK context for the target BS
   b) Retrieve the cached AK context for the serving BS

11-F: Reentry Authentication Wait (TBS changed) → Reentry Authentication Wait
   a) Generate the AK context of new target BS

12-F: Reentry Authentication Wait (Reentry Completed) → Authenticated
   a) Update the AK context for the target BS

13-D,E,F: Any state except Stopped, SA-TEK-Response Wait, and Not Authenticated (Authentication Expired) → Stopped
   a) Stop TEK FSMs
   b) Stop the Authorization FSM

14-B: Not Authenticated (EAP Failure) → Stopped
   a) Stop the Authorization FSM

14-D: Authenticated (EAP Failure) → Stopped
   a) Stop TEK FSMs
   b) Stop the Authorization FSM

15-B,C: Not Authenticated and SA-TEK-Response Wait (External Stop) → Stopped
   a) Stop the Authorization FSM

15-D,E,F: Any state except Stopped, Not Authenticated, and SA-TEK-Response Wait (External Stop) → Stopped
   a) Stop TEK FSMs
   b) Stop Authorization Grace Timer
   c) Stop the Authorization FSM

7.2.2.6 TEK state machine

The TEK state machine consists of seven states and eleven events (including receipt of messages) that may trigger state transitions. Like the Authorization state machine, the TEK state machine is presented in both a state flow diagram (Figure 166) and a state transition matrix (Table 209). As was the case for the Authorization state machine, the state transition matrix shall be used as the definitive specification of protocol actions associated with each state transition.

Shaded states in Figure 166 (Operational, Rekey Wait, Rekey Reauthorize Wait, and M&B Rekey Interim Wait) have valid keying material and encrypted traffic may be sent.

The SAID may be replaced by the GSAID for the multicast service or the broadcast service. And, the TEK may be also replaced by the GTEK for the multicast service or the broadcast service.

The Authorization state machine starts an independent TEK state machine for each of its authorized SAIDs. As mentioned in 7.2.2, the BS maintains two active TEKs per SAID.
For the unicast service, the BS includes in its Key Replies both of these TEKs, along with their remaining lifetimes. The BS encrypts DL traffic with the older of its two TEKs and decrypts UL traffic with either the older or newer TEK, depending upon which of the two keys the SS was using at the time. The SS encrypts UL traffic with the newer of its two TEKs and decrypts DL traffic with either the older or newer TEK, depending upon which of the two keys the BS was using at the time. See 7.3 for details on SS and BS key usage requirements.

For the multicast service or the broadcast service, the BS may include both of GTEKs in its Key Reply messages when an SS request traffic keying material. Furthermore, the BS may include the newer GTEK in the PKMv2 Group-Key-Update-Command message when the BS transmits the new traffic keying material in key push mode. The BS encrypts DL traffic with current GTEK. The SS decrypts DL traffic with either the older or newer GTEK, depending upon which of the two keys the BS was using at the time. See 7.9 for details on SS and BS key usage requirements.
Through operation of a TEK state machine, the SS attempts to keep its copies of an SAID’s TEKs synchronized with those of its BS. A TEK state machine issues Key Requests to refresh copies of its SAID’s keying material soon after the scheduled expiration time of the older of its two TEKs and before the expiration of its newer TEK. To accommodate for SS/BS clock skew and other system processing and transmission delays, the SS schedules its Key Requests a configurable number of seconds before the newer TEK’s estimated expiration in the BS. With the receipt of the Key Reply, the SS shall always update its records with the TEK parameters from both TEKs contained in the Key Reply message. TEK parameters are contained in the two PKMv2 Group-Key-Update-Command message messages for the multicast service or the broadcast service.

### 7.2.2.6.1 States

- **Start**: This is the initial state of the FSM. No resources are assigned to or used by the FSM in this state—e.g., all timers are off, and no processing is scheduled.
— **Op (operational) Wait:** The TEK state machine has sent its initial request (Key Request) for its SAID’s keying material (TEK and CBC IV), and is waiting for a reply from the BS.

— **Op Reauth (reauthorize) Wait:** The wait state the TEK state machine is placed in if it does not have valid keying material while the Authorization state machine is in the middle of a reauthorization cycle.

— **Operational:** The SS has valid keying material for the associated SAID.

— **Rekey Wait:** The TEK Refresh Timer has expired and the SS has requested a key update for this SAID. Note that the newer of its two TEKs has not expired and may still be used for both encrypting and decrypting data traffic.

— **Rekey Reauth Wait:** The wait state the TEK state machine is placed in if the TEK state machine has valid traffic keying material, has an outstanding request for the latest keying material, and the Authorization state machine initiates a reauthorization cycle.

— **M&B (multicast and broadcast) Rekey Interim Wait:** This state is defined only for the multicast service or the broadcast service. This state is the wait state the TEK state machine is placed in if the TEK state machine has valid traffic keying material and receives the new GKEK from the BS.

### 7.2.2.6.2 Messages

Note that the message formats are defined in detail in 6.3.2.3.9.

— **Key Request:** Request a TEK for this SAID. Sent by the SS to the BS and authenticated with keyed message digest. The message authentication key is derived from the AK.

— **Key Reply:** Response from the BS carrying the two diversity sets of traffic keying material for this SAID. Sent by the BS to the SS, it includes the SAID’s TEKs, encrypted with a KEK derived from the AK or the GSAID’s GTEK, encrypted with a GKEK randomly generated from the BS or the ASA server. The Key Reply message is authenticated with a keyed message digest; the authentication key is derived from the AK.

— **Key Reject:** Response from the BS to the SS to indicate this SAID is no longer valid and no key will be sent. The Key Reject message is authenticated with a keyed message digest; the authentication key is derived from the AK.

— **TEK Invalid:** The BS sends an SS this message if it determines that the SS encrypted an UL PDU with an invalid TEK, i.e., an SAID’s TEK key sequence number, contained within the received PDU’s MAC header, is out of the BS’s range of known, valid sequence numbers for that SAID.

— **Key Update Command:** Push a GTEK for this GSAID for the multicast service or the broadcast service. Sent by the BS to the SS and authenticate with keyed message digest. The message authentication key is derived from the AK in the PKMv2 Group-Key-Update-Command message for the GKEK update mode. The message authentication key is derived from the GKEK in the Key Update Command message for the GTEK update mode.

### 7.2.2.6.3 Events

— **Stop:** Sent by the Authorization FSM to an active (non-START state) TEK FSM to terminate TEK FSM and remove the corresponding SAID’s keying material from the SS’s key table. See Figure 159.

— **Authorized:** Sent by the Authorization FSM to a non-active (START state) TEK FSM to notify TEK FSM of successful authorization. See Figure 159.

— **Authorization Pending (Auth Pend):** Sent by the Authorization FSM to TEK FSM to place TEK FSM in a wait state while Authorization FSM completes reauthorization. See Figure 159.

— **Authorization Complete (Auth Comp):** Sent by the Authorization FSM to a TEK FSM in the Operational Reauthorize Wait or Rekey Reauthorize Wait states to clear the wait state begun by the prior Authorization Pending event. See Figure 159.

— **TEK Invalid:** This event is triggered by either an SS’s data packet decryption logic or by the receipt of a TEK Invalid message from the BS.
An SS’s data packet decryption logic triggers a TEK Invalid event if it recognizes a loss of TEK key synchronization between itself and the encrypting BS. For example, an SAID’s TEK key sequence number, contained within the received DL MAC PDU header, is out of the SS’s range of known sequence numbers for that SAID.

A BS sends an SS a TEK Invalid message, triggering a TEK Invalid event within the SS, if the BS’s decryption logic recognizes a loss of TEK key synchronization between itself and the SS.

- **Timeout**: A retry timer timeout. Generally, the particular request is retransmitted.
- **TEK Refresh Timeout**: The TEK refresh timer timed out. This timer event signals the TEK state machine to issue a new Key Request in order to refresh its keying material. The refresh timer is set to fire a configurable duration of time (TEK Grace Time) before the expiration of the newer TEK the SS currently holds. This is configured via the BS to occur after the scheduled expiration of the older of the two TEKs.
- **GKEK Updated**: This event is triggered when the SS receives the new GKEK through the PKMv2 Group-Key-Update-Command message for the GKEK update mode.
- **GTEK Updated**: This event is triggered when the SS receives the new GTEK and traffic keying material through the PKMv2 Group-Key-Update-Command message for the GTEK update mode.

### 7.2.2.6.4 Parameters

All configuration parameter values take the default values from Table 555 or may be specified in Auth Reply message.

- **Operational Wait Timeout**: Timeout period between sending of Key Request messages from the Op Wait state (see 11.9.18.4).
- **Rekey Wait Timeout**: Timeout period between sending of Key Request messages from the Rekey Wait state (see 11.9.18.5).
- **TEK Grace Time**: Time interval, in seconds, before the estimated expiration of a TEK that the SS starts rekeying for a new TEK. TEK Grace Time takes the default value from Table 555 or may be specified in a configuration setting within the Auth Reply message and is the same across all SAIDs (see 11.9.18.6).
- **MK&B TEK Grace Time**: Time interval, in seconds, before the estimated expiration of an old distributed GTEK.

### 7.2.2.6.5 Actions

Actions taken in association with state transitions are listed by `<event> (<rcvd message>) --> <state>`:

1-B **Op Wait (Stop) → Start**
   a) Clear Key Request retry timer
   b) Terminate TEK FSM

1-C **Op Reauth Wait (Stop) → Start**
   a) Terminate TEK FSM

1-D **Operational (Stop) → Start**
   a) Clear TEK refresh timer, which is timer set to go off “TEK Grace Time” seconds prior to the TEK’s scheduled expiration time
   b) Terminate TEK FSM
   c) Remove SAID keying material from key table
1-E  Rekey Wait \((Stop)\) → Start
   a) Clear Key Request retry timer
   b) Terminate TEK FSM
   c) Remove SAID keying material from key table

1-F  Rekey Reauth Wait \((Stop)\) → Start
   a) Terminate TEK FSM
   b) Remove SAID keying material from key table

2-A  Start \((Authorized)\) → Op Wait
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout

3-B  Op Wait \((Auth\ Pend)\) → Op Reauth Wait
   a) Clear Key Request retry timer

3-E  Rekey Wait \((Auth\ Pend)\) → Rekey Reauth Wait
   a) Clear Key Request retry timer

4-C  Op Reauth Wait \((Auth\ Comp)\) → Op Wait
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout

4-F  Rekey Reauth Wait \((Auth\ Comp)\) → Rekey Wait
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Rekey Wait Timeout

5-D  Operational \((TEK\ Invalid)\) → Rekey_Wait
   a) Send a Key Request message to BS
   b) Set Key Request retry timer to Rekey Wait Timeout

6-B  Op Wait \((Timeout)\) → Op Wait
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Operational Wait Timeout

6-E  Rekey Wait \((Timeout)\) → Rekey Wait
   a) Send Key Request message to BS
   b) Set Key Request retry timer to Rekey Wait Timeout
7-D  Operational (*TEK Refresh Timeout*) \(\rightarrow\) Rekey Wait

a) Send Key Request message to BS  
b) Set Key Request retry timer to Rekey Wait Timeout

7-G  M&B Rekey Interim Wait (*TEK Refresh Timeout*) \(\rightarrow\) Rekey Wait

a) Send Key Request message to BS  
b) Set Key Request retry timer to Rekey Wait Timeout

8-B  Op Wait (Key Reply) \(\rightarrow\) Operational

a) Clear Key Request retry timer  
b) Process contents of Key Reply message and incorporate new keying material into key database  
c) Set the TEK refresh timer to go off “TEK Grace Time” seconds prior to the newer key’s scheduled expiration

8-E  Rekey Wait (Key Reply) \(\rightarrow\) Operational

a) Clear Key Request retry timer  
b) Process contents of Key Reply message and incorporate new keying material into key database  
c) Set the TEK refresh timer to go off “TEK Grace Time” seconds prior to the newer key’s scheduled expiration

9-B  Op Wait (Key Reject) \(\rightarrow\) Start

a) Clear Key Request retry timer  
b) Terminate TEK FSM

9-E  Rekey Wait (Key Reject) \(\rightarrow\) Start

a) Clear Key Request retry timer  
b) Terminate TEK FSM  
c) Remove SAID keying material from key table

10-D  Operational (*GKEK Updated*) \(\rightarrow\) M&B Rekey Interim Wait

a) Process contents of PKMv2 Group-Key-Update-Command message for the GKEK update mode and incorporate new GKEK into key database

11-G  M&B Rekey Interim Wait (*GTEK Updated*) \(\rightarrow\) Operational

a) Clear Key Request retry timer  
b) Process contents of PKMv2 Group-Key-Update-Command message for the GTEK update mode and incorporate new traffic keying material into key database  
c) Set the TEK refresh timer to go off “TEK Grace Time” seconds prior to the key’s scheduled expiration
7.3 Dynamic SA creation and mapping

Dynamic Security Associations are SAs that a BS establishes and eliminates dynamically. SSs learn the mapping of a particular privacy-enabled service flow to specific SA through the exchange of DSx-REQ/RSP messages.

7.3.1 Dynamic SA creation

The BS may dynamically establish SAs by issuing an SA Add message. Upon receiving an SA Add message, the SS shall start a TEK state machine for each SA listed in the message.

7.3.2 Dynamic mapping of SA

When creating a new service flow, an SS may request an existing SA be used by passing the SAID of the SA in a DSA-REQ or DSC-REQ message. The BS checks the SS’s authorization for the requested SA and generates appropriate response using a DSA-RSP or DSC-RSP message correspondingly.

With BS-initiated dynamic service creations, a BS may also map a new service flow to an existing SA that is supported by a specific SS. The SAID of the SA shall be communicated to the SS in a DSA-REQ or DSC-REQ message.

7.4 Key usage

7.4.1 BS key usage

The BS is responsible for maintaining keying information for all SAs. The PKM protocol defined in this specification describes a mechanism for synchronizing this keying information between a BS and its client SS.

7.4.1.1 AK key lifetime

At initial network entry, if the security is enabled during the basic capabilities negotiation, the authorization procedure shall be initiated. The authorization procedure activates a new AK. This AK shall remain active until it expires according to its predefined AK Lifetime, a BS system configuration parameter.

In PKMv1, the AK’s active lifetime a BS reports in an Authorization Reply message shall reflect, as accurately as an implementation permits, the remaining lifetimes of AK at the time the Authorization Reply message is sent. In PKMv2, AK lifetime is determined by either PMK lifetime or PAK lifetime, or both of them. The old AK may be used until the frame number specified in PKMv2 SA-TEK-Response message.

If an SS fails to reauthorize before the expiration of its current AK, the BS shall hold no active AKs for the SS and shall consider the SS unauthorized. A BS shall remove from its keying tables all TEKs associated with an unauthorized SS’s SA.

7.4.1.2 AK transition period on BS side

The BS shall always be prepared to start re-authentication upon request. The BS shall be able to support two simultaneously active AKs for each client SS. The BS has two active AKs during an AK transition period; the two active keys have overlapping lifetimes.

In PKMv1, an AK transition period begins when the BS receives an Auth Request message from an SS and the BS has a single active AK for that SS. In response to this Auth Request, the BS activates a second AK [see point (a) and (d) in Figure 167], which shall have a key sequence number one greater (modulo 16) than
that of the existing AK and shall be sent back to the requesting SS in an Auth Reply message. The BS shall set the active lifetime of this second AK to be the remaining lifetime of the first AK [between points (a) and (c) in Figure 167], plus the predefined AK Lifetime; thus, the second, “newer” key shall remain active for one AK Lifetime beyond the expiration of the first, “older” key. The key transition period shall end with the expiration of the older key. This is depicted on the right-hand side of Figure 167.

As long as the BS is in the midst of an SS’s AK transition period, and thus is holding two active AKs for that SS, it shall respond to Auth Request messages with the newer of the two active keys. Once the older key expires, an Auth Request shall trigger the activation of a new AK, and the start of a new key transition period.

In PKMv2, the new AK is activated by PKMv2 SA-TEK 3-way handshake as follows.

Once the PKMv2 SA-TEK 3-way handshake begins, the BS and the SS shall use the new AK for the 3-way handshake messages. The other messages shall continue to use the old AK until SA-TEK 3-way handshake is completed successfully. The old AK shall be maintained until the frame number specified in PKMv2 SA-TEK-Response message. The key sequence number of the new AK is incremented (modulo 16) by the rule shown in Table 203. The rule to decide the AK lifetime is also shown in Table 203.

7.4.1.3 BS usage of AK

The BS shall use keying material derived from the SS’s AK for the following:

a) Verifying the C/HMAC-Digests in Key Request or PKMv2-Key-Request messages received from that SS,

b) Calculating the C/HMAC-Digests it writes into Key Reply/PKMv2-Key-Reply, Key Reject/PKMv2-Key-Reject, and TEK Invalid/PKMv2-TEK-Invalid messages sent to that SS, and

c) Encrypting the TEK in the Key Reply/PKMv2-Key-Reply messages it sends to that SS.

A BS shall use a C/HMAC_KEY_U (see 7.5.4.3 and Figure 7.5.4.4) derived from one of the SS’s active AKs to verify the C/HMAC-Digest in Key Request/PKMv2-Key-Request messages received from the SS. The AK Key Sequence Number accompanying each Key Request/PKMv2-Key-Request message allows the BS to determine which C/HMAC_KEY_U was used to authenticate the message. In PKMv1, if the AK Key Sequence Number indicates the newer of the two AKs, the BS shall identify this as an implicit acknowledgment that the SS has obtained the newer of the SS’s two active AKs [see points (b) in Figure 167].

A BS shall use a C/HMAC_KEY_D derived from the active AK selected above (see also 7.5.4.3 and Figure 7.5.4.4) when calculating C/HMAC-Digests in Key Reply/PKMv2-Key-Reply, Key Reject/PKMv2-Key-Reject, and TEK Invalid/PKMv2-TEK-Invalid messages. When sending Key Reply/PKMv2-Key-Reply, Key Reject/PKMv2-Key-Reject, or TEK Invalid/PKMv2-TEK-Invalid messages within a key transition period (i.e., when two active AKs are available), if the newer key has been implicitly acknowledged, the BS shall use the newer of the two active AKs. If the newer key has not been implicitly acknowledged, the BS shall use the older of the two active AKs to derive the KEK and the C/HMAC_KEY_D.

The BS shall use a KEK derived from an active AK when encrypting the TEKs in the Key Reply/PKMv2-Key-Reply messages. The right-hand side of Figure 167 illustrates the BS’s policy regarding its use of AKs in PKMv1, where the shaded portion of an AK’s lifetime indicates the time period during which that AK shall be used to derive the C/HMAC_KEY_U, C/HMAC_KEY_D, and KEK.

For calculating the C/HMAC-Digest in the C/HMAC Tuple attribute, the BS shall use the C/HMAC_KEY_U and C/HMAC_KEY_D derived from one of the active AKs. For signing messages, if the newer AK has been implicitly acknowledged, the BS shall use the newer of the two active AKs to derive the
Figure 167—AK management in BS and SS
C/HMAC_KEY_D. If the newer key has not been implicitly acknowledged, the BS shall use the older of the two active AKs to derive the C/HMAC_KEY_D. The C/HMAC Key Sequence Number in the C/HMAC Tuple, equal to the AK’s sequence number from which the C/HMAC_KEY_D was derived, enables the SS to correctly determine which C/HMAC_KEY_D was used for message authentication.

When receiving messages containing the C/HMAC Tuple attribute, the BS shall use the C/HMAC_KEY_U indicated by the C/HMAC Key Sequence Number to authenticate the messages.

### 7.4.1.4 TEK lifetime

The BS shall maintain two sets of active TEKs (and their associated Initialization Vectors, or IVs) per SAID, corresponding to two successive generations of keying material. The two generations of TEKs shall have overlapping lifetimes determined by TEK Lifetime, a predefined BS system configuration parameter. The newer TEK shall have a key sequence number one greater (modulo 4) than that of the older TEK. Each TEK becomes active halfway through the lifetime of its predecessor and expires halfway through the lifetime of its successor. Once a TEK’s lifetime expires, the TEK becomes inactive and shall no longer be used.

The Key Reply or PKMv2-Key-Reply messages sent by a BS contain TEK parameters for the two active TEKs. The TEKs’ active lifetimes a BS reports in a Key Reply or PKMv2-Key-Reply message shall reflect, as accurately as an implementation permits, the remaining lifetimes of these TEKs at the time the Key Reply or PKMv2-Key-Reply message is sent.

### 7.4.1.5 BS usage of TEK

The BS transitions between the two active TEKs differently, depending on whether the TEK is used for DL or UL traffic. For each of its SAIDs, the BS shall transition between active TEKs according to the following rules:

a) At expiration of the older TEK, the BS shall immediately transition to using the newer TEK for encryption.

b) The UL transition period begins from the time the BS sends the newer TEK in a Key Reply or PKMv2-Key-Reply message and concludes once the older TEK expires.

It is the responsibility of the SS to update its keys in a timely fashion; the BS shall transition to a new DL encryption key regardless of whether a client SS has retrieved a copy of that TEK.

The BS uses the two active TEKs differently, depending on whether the TEK is used for DL or UL traffic. For each of its SAIDs, the BS shall use the two active TEKs according to the following rules:

— The BS shall use the older of the two active TEKs for encrypting DL traffic.
— The BS shall be able to decrypt UL traffic using either the older or newer TEK.

Note that the BS encrypts with a given TEK for only the second half of that TEK’s total lifetime. The BS is able, however, to decrypt with a TEK for the TEK’s entire lifetime.
Figure 168 illustrates the management of an SA’s TEKs, where the shaded portion of a TEK’s lifetime indicates the time period during which that TEK shall be used to encrypt MAC PDU payloads.

7.4.2 SS key usage

In PKMv1 or PKMv2 RSA-based authentication, the SS is responsible for sustaining authorization with its BS and maintaining an active AK. In PKMv2 EAP-based authentication, reauthorization can be initiated by either BS or SS to refresh the AK. An SS shall be prepared to use its two most recently obtained AKs according to the manner described in 7.4.2.1 through 7.4.2.3.
7.4.2.1 SS reauthorization

AKs have a limited lifetime and shall be periodically refreshed. In PKMv1, an SS refreshes its AK by reissuing an Auth Request to the BS. The Authorization State Machine (7.2.1.5) manages the scheduling of Auth Requests for refreshing AKs. In PKMv2 RSA-based authentication, the SS refreshes its AK by issuing a PKMv2 RSA-Request message. In PKMv2 EAP-based authentication, reauthorization can be initiated by either BS or SS to refresh the AK. The SS initiates reauthorization by issuing PKMv2 EAP-Start message to the BS. The BS initiates reauthorization by issuing PKMv2 EAP-Transfer message encapsulating EAP request/identity to the SS. The authorization state machine for PKMv2 EAP-based authentication is described in Figure 7.2.2.5

In PKMv1, an SS’s Authorization state machine schedules the beginning of reauthorization a configurable duration of time, the Authorization Grace Time, [see points (x) and (y) in Figure 167], before the SS’s latest AK is scheduled to expire. The Authorization Grace Time is configured to provide an SS with an authorization retry period that is sufficiently long to allow for system delays and provide adequate time for the SS to successfully complete an Authorization exchange before the expiration of its most current AK.

In PKMv2 EAP-based authentication, reauthorization is triggered when any of the following conditions are met: 1) Authorization Grace Timer expires, 2) CMAC_KEY_COUNT or CMAC_PN_* approaches the maximum number, 3) PKMv2 EAP-Start message is sent by the SS, 4) PKMv2 EAP-Transfer message encapsulating EAP request/identity is sent by the BS.

Note that the BS does not require knowledge of the Authorization Grace Time. The BS, however, shall track the lifetimes of its AKs and shall deactivate a key once it has expired.

7.4.2.2 SS usage of AK

An SS shall use the C/HMAC_KEY_U derived from the newer of its two most recent AKs when calculating the C/HMAC-Digests it attaches to Key Request or PKMv2-Key-Request messages.

The SS shall be able to use the C/HMAC_KEY_D derived from either of its two most recent AKs to authenticate Key Reply, Key Reject, and TEK Invalid messages for PKMv1, or PKMv2-Key-Reply, PKMv2-Key-Reject, and PKMv2-TEK-Invalid messages for PKMv2. The SS shall be able to decrypt an encrypted TEK in a Key Reply or PKMv2-Key-Reply message with the KEK derived from either of its two most recent AKs. The SS shall use the accompanying AK Key Sequence Number to determine which set of keying material to use.

The left-hand side of Figure 167 illustrates an SS’s maintenance and usage of its AKs in PKMv1, where the shaded portion of an AK’s lifetime indicates the time period during which that AK shall be used to decrypt TEKs. Even though it is not part of the message exchange, Figure 167 also shows the implicit acknowledgment of the reception of a new AK via the transmission of a Key Request message using the key sequence of the new AK.

An SS shall use the C/HMAC_KEY_U derived from the newer of its two most recent AKs when calculating the C/HMAC-Digests of the C/HMAC Tuple attribute.

7.4.2.3 SS usage of TEK

An SS shall be capable of maintaining two successive sets of traffic keying material per authorized SAID. Through operation of its TEK state machines, an SS shall request a new set of traffic keying material a configurable amount of time, the TEK Grace Time [see points (x) and (y) in Figure 168], before the SS’s latest TEK is scheduled to expire.

For each of its authorized SAIDs, the SS
— Shall use the newer of its two TEKs to encrypt UL traffic, and
— Shall be able to decrypt DL traffic encrypted with either of the TEKs.

The left-hand side of Figure 168 illustrates the SS’s maintenance and usage of an SA’s TEKs, where the shaded portion of a TEK’s lifetime indicates the time period during which that TEK shall be used to encrypt MAC PDU payloads.

7.5 Cryptographic methods

This subclause specifies the cryptographic algorithms and key sizes used by the PKM protocol. All SS and BS implementations shall support the method of packet data encryption defined in 7.5.1.1, encryption of the TEK as specified in 7.5.2, and message digest calculation as specified in 7.5.3.

All inputs to key derivation and other supporting functions shall be byte aligned. Furthermore, each byte shall be in canonical form as defined in IEEE Std 802 where the leftmost bit in each byte is the most significant bit and the rightmost bit is the least significant bit.

7.5.1 Data Encryption methods

7.5.1.1 Data encryption with DES in CBC mode

If the data encryption algorithm identifier in the cryptographic suite of an SA equals 0x01, data on connections associated with that SA shall use the CBC mode of the DES algorithm (FIPS 46-3, FIPS 74, and FIPS 81) to encrypt the MAC PDU payloads.

The CBC IV shall be calculated as follows:

— In the DL, the CBC shall be initialized with the exclusive-or (XOR) of
  — The IV parameter included in the TEK keying information and
  — The current frame number (right justified).
— In the UL, the CBC shall be initialized with the XOR of
  — The IV parameter included in the TEK keying information and
  — The frame number of the frame where the relevant UL-MAP was transmitted.

Residual termination block processing shall be used to encrypt the final block of plaintext when the final block is less than 64 bits. Given a final block having \( n \) bits, where \( n \) is less than 64, the next-to-last ciphertext block shall be DES encrypted a second time, using the electronic code book (ECB) mode, and the \( n \) MSBs of the result are XORed with the final \( n \) bits of the payload to generate the short final cipher block. In order for the receiver to decrypt the short final cipher block, the receiver DES encrypts the next-to-last ciphertext block, using the ECB mode, and XORs the \( n \) MSBs with the short final cipher block in order to recover the short final cleartext block. This encryption procedure is depicted in Figure 9.4 of Schneier [B43].

In the special case when the payload portion of the MAC PDU is less than 64 bits, the IV shall be DES encrypted and the \( n \) MSBs of the resulting ciphertext, corresponding to the number of bits of the payload, shall be XORed with the \( n \) bits of the payload to generate the short cipher block.\(^{20}\)

\(^{20}\)If two or more PDUs with less than 8 byte payloads are transmitted in the same frame using the same SA, the XOR of the payload plaintexts can be found easily. In practice, this situation is very unlikely to occur, as payloads are typically larger than 8 bytes. In the case that multiple payloads of less than 8 bytes are to be transmitted in the same frame on the same SA and service, packing of the short SDUs into a single PDU will eliminate this weakness. If the SDUs are for different services, packing the SDUs with zero-length fictitious SDUs allows the use of the PSH to extend the size of the PDU to at least 8 bytes.
7.5.1.2 Data encryption with AES in CCM mode

If the data encryption algorithm identifier in the cryptographic suite of an SA equals 0x02, data on connections associated with that SA shall use the CCM mode of the AES algorithm (NIST Special Publication 800-38C and FIPS 197) to encrypt the MAC PDU payloads.

7.5.1.2.1 PDU payload format

The MAC PDU payload shall be prepended with a 4-byte PN (Packet Number). The PN shall be encoded in the MAC PDU least significant byte first. The PN shall not be encrypted.

The plaintext PDU shall be encrypted and authenticated using the active TEK, according to the CCM specification. This includes appending an 8-byte integrity check value (ICV) to the end of the payload and encrypting both the plaintext payload and the appended ICV.

The ciphertext message authentication code is transmitted so that byte index 0 (as enumerated in NIST Special Publication 800-38) is transmitted first and byte index 7 is transmitted last (i.e., LSB first).

The processing yields a payload that is 12 bytes longer than the plaintext payload. See Figure 169.

![Figure 169—Encrypted payload format in AES-CCM mode](image)

7.5.1.2.2 Packet number (PN)

The PN associated with an SA shall be set to 1 when the SA is established and when a new TEK is installed. After each PDU transmission, the PN shall be incremented by 1. On UL connections, the PN shall be XORed with 0x80000000 prior to encryption and transmission. On DL connections, the PN shall be used without such modification.

Any tuple value of \{PN, KEY\} shall not be used more than once for the purposes of transmitting data. The SS shall ensure that a new TEK is requested and transferred before the PN on either the SS or BS reaches 0x7FFFFFFF. If the PN in either the SS or BS reaches 0x7FFFFFFF without new keys being installed, transport communications on that SA shall be halted until new TEKs are installed.

---

21 This achieves the splitting of the PN space. 0x00000001 – 0x7FFFFFFF for the DL and 0x80000001 – 0xFFFFFFFF on the UL, preventing a PN collision between the UL and DL.

22 Sending two packets encoded with the same key and PN will eliminate all security guarantees of CCM mode.
7.5.1.2.3 CCM algorithm

The NIST CCM specification defines a number of algorithm parameters. These parameters shall be fixed to specific values when used in SAs with a data encryption algorithm identifier of 0x02.

‘Tlen’ shall equal 64 and t shall equal 8, meaning, the number of bytes in the Message Authentication field shall be set to 8. Consistent with the CCM specification, the 3-bit binary encoding \([(t-2)/2]_3\) of bits 5, 4, and 3 of the Flags byte in B0 shall be 011.

The size q of the Length field Q shall be set to 2. Consistent with the CCM specification, the 3-bit binary encoding \([q-1]_3\) of the q field in bits 2, 1, and 0 of the Flags byte in B0 shall be 001.

The length a of the associated data string A shall be set to 0.

The nonce shall be 13 bytes long as shown in Figure 170. Bytes 0 through 4 shall be set to the first 5 bytes of the generic MAC header (thus excluding the HCS). The HCS of the generic MAC header is not included in the nonce since it is redundant. Bytes 5 through 8 are reserved and shall be set to 0x00000000. Bytes 9 through 12 shall be set to the value of the PN. The PN bytes shall be ordered so that byte 9 shall take the least significant byte and byte 12 shall take the most significant byte.

### 7.5.1.2.4 Receive processing rules

On receipt of a PDU the receiving SS or BS shall decrypt and authenticate the PDU consistent with the NIST CCM specification configured as specified in 7.5.1.2.3.

Packets that are found to be not authentic shall be discarded.

Receiving BS or SSs shall maintain a record of the highest value PN receive for each SA.

The receiver shall maintain a PN window whose size is specified by the PN_WINDOW_SIZE parameter for SAs and management connections as defined in 11.8.4.4. Any received PDU with a PN lower than the beginning of the PN window shall be discarded as a replay attempt. The receiver shall track PNs within the PN window. Any PN that is received more than once shall be discarded as a replay attempt. Upon reception of a PN, which is greater than the end of the PN window, the PN window shall be advanced to cover this PN.

### 7.5.1.2.5 AES-CCM mode example encrypted MAC PDUs

The following two examples show MAC PDUs in both plaintext and enciphered form in transmission order. In addition, the post-decryption plaintext of the message authentication code is shown.

**Example AES-CCM PDU #1 (Hex)**

**Plaintext PDU**

- Generic MAC header = 00 40 0A 06 C4 30
- Payload = 00 01 02 03

**Ciphertext PDU where TEK = 0xD50E18A844AC5BF38E4CD72D9B0942E5 and PN=0x2157F6BC**

- Generic MAC header = 40 40 1A 06 C4 5A
- PN field = BC F6 57 21
- Encrypted payload = E7 55 36 C8
- Encrypted message authentication code = 27 A8 D7 1B 43 2C A5 48
- CRC32 for SC and OFDM mode = CB B6 5F 48
- CRC32 for OFDMA mode = 1B D1 BA 21

**After decryption**

- Plaintext message authentication code = 01 59 09 A0 ED CC 21 D3
Example AES-CCM PDU #2 (Hex)

**Plaintext PDU**

- Generic MAC header = 00 40 27 7E B2 AD
- Payload = 00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F 10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F

**Ciphertext PDU where TEK = 0xB74EB0E4F81AD63D121B7E9AECCD268F and PN=0x78D07D08**

- Generic MAC header = 40 40 37 7E B2 C7
- PN field = 08 7D D0 78
- Encrypted payload = 71 3F B1 22 B9 73 4F DB FD 68 2E AD 9D CA 9F 44 1F 62 FE 0F 4A 2C 45 B5 53 17 3D 66 5B 2D 53 C1 B3
- Encrypted message authentication code = E7 E4 8D 2D B7 61 CF 94
- CRC32 for SC and OFDM mode = 92 1B 32 41
- CRC32 for OFDMA mode = FD 03 7B 1D

**After decryption**

- Plaintext message authentication code = 0B DB 85 3C 0A CA E6 5F

### 7.5.1.3 Data encryption with AES in CTR mode

If the data encryption algorithm identifier in the cryptographic suite of an MBS GSA equals 0x80, data on connections associated with that SA shall use the CTR mode of the AES algorithm (NIST Special Publication 800-38A, FIPS 197, IETF RFC 3686) to encrypt the MAC PDU payloads. In MBS, the AES block size and cipher counter block are 128 bits.

#### 7.5.1.3.1 Encrypted MBS PDU payload format

CTR mode requires unique initial counter and key pair across all messages. This subclause describes the initialization of the 128-bit initial counter, constructed from the 24-bit PHY synchronization field or frame number and a new 8-bit Rollover counter (ROC).

ROC shall be reset to zero upon obtaining a new key. The first 3 most significant bits of the ROC is the rollover counter for the frame number, i.e., when the frame number reaches 0x000000 (from 0xFFFFFFFF) it is incremented by 1 mod 8. The 5 least significant bits of ROC shall be allocated to MBS MAC PDUs in such manner that no two MBS MAC PDUs in the same frame using the same MTK have the same ROC value.

Using this method, up to 32 PDUs per frame using the same MTK can be supported. A new encryption key (MTK) is required every $2^{27}$ frames.

The PDU payload for AES-CTR encryption shall be prepended with the 8-bit ROC, i.e., the ROC is the 8 MSBs of the 32-bit nonce. The ROC shall not be encrypted.

Any tuple value of \{AES Counter, KEY\} shall not be used more than once for the purposes of encrypting a block. The SS and BS shall ensure that a new MGTEK is requested and transferred, and a new MTK is derived and ready for use before the 3 MSB of ROC concatenated with the frame number reaches 0x7FF.

A 32-bit nonce NONCE = n0 | n1 | n2 | n3 (n0 being the most significant byte and n3 the least significant byte) is made of ROC and 24 bits frame number in the following way: n0 = ROC and n1, n2, n3 are the byte representation of frame-number in MSB first order. NONCE shall be repeated four times to construct the 128-bit counter block required by the AES-128 cipher. (initial counter = NONCE|NONCE|NONCE|NONCE). When incremented, this 16-byte counter shall be treated as a big endian number.
This mechanism can reduce per-PDU overhead of transmitting the full counter. At the most $2^{32}$ PDUs can be encrypted with a single MTK.

The plaintext PDU shall be encrypted using the active MBS_Traffic_key (MTK) derived from MAK and MGTEK, according to CTR mode specification. A different 128-bit counter value is used to encrypt each 128-bit block within a PDU.

The processing yields a payload that is 8 bits longer than the plaintext payload. See Figure 173.

7.5.1.4 Data encryption with AES in CBC mode

If the data encryption algorithm identifier in the cryptographic suite of an SA equals 0x03, data on connections associated with that SA shall use the CBC mode of the AES algorithm (NIST Special Publication 800-38A and FIPS 197) to encrypt the MAC PDU payloads.

Residual termination block processing shall be used to encrypt the final block of plaintext when the final block is less than the cipher block size. Given a final block having n bits, where n is less than the cipher block size m, the next-to-last ciphertext block shall be divided into two parts. One of the two parts is n bits, the other part is m-n bits. The former shall be sent to receiver as the final block ciphertext. Padding the final short block to obtain a complete plaintext block, then encrypt it with AES algorithm in CBC mode. The encryption and decryption procedure is depicted in Figure 174.

In the special case when the payload portion of the MAC PDU is less than the cipher block size, the n MSBs of the generated CBC IV, corresponding to the number of bits of the payload, shall be XORed with the n bits of the payload to generate the short cipher block.
7.5.1.4.1 CBC IV generation

The Zero Hit Counter is initialized into zero when the Key Reply message is received. The Zero Hit Counter increases by one if the previous PHY Frame number is equal to or greater than the current PHY Frame number.

The CBC IV is generated as the result of the AES block ciphering algorithm with the key of TEK. Its plain text for the CBC IV generation is calculated with the exclusive-or (XOR) of (1) the CBC IV parameter value included in the TEK keying information, and (2) the 128-bits content which is a concatenation of the 48-bit MAC PDU header, the 32-bit PHY Synchronization value of the MAP that a data transmission occurs, and the XOR value of the 48-bit SS MAC address and the Zero Hit Counter.

The CBC IV shall be updated every MAC PDUs. See Figure 175.

If the MAC PDU is decoded from several channel coded blocks transmitted at different frames in HARQ operation, the MAC PDU payload shall be decrypted with the CBC IV value which are generated from the PHY Synchronization value of the MAP when spid = 0.
7.5.2 Encryption of TEK

The options listed in 7.5.2.1 through 7.5.2.3 may be used.

7.5.2.1 Encryption of TEK with 3-DES

This method of encrypting the TEK shall be used for SAs with the TEK encryption algorithm identifier in the cryptographic suite equal to 0x01.
The BS encrypts the value fields of the TEK in the Key Reply messages it sends to client SS. This field is encrypted using two-key 3-DES in the EDE mode (Schneier [B43]).

encryption: $C = E_{k1}(D_{k2}(E_{k1}(P)))$

decryption: $P = D_{k1}(E_{k2}(D_{k1}(C)))$

$P =$ Plaintext 64-bit TEK

$C =$ Ciphertext 64-bit TEK

$k1 =$ most significant 64 bits of the 128-bit KEK

$k2 =$ least significant 64 bits of the 128-bit KEK

$E[ ] =$ 56-bit DES ECB mode encryption

$D[ ] =$ 56-bit DES ECB decryption

Subclause 7.5.4 describes how the KEK is derived from the AK.

7.5.2.2 Encryption of TEK with RSA

The RSA method of encrypting the TEK (PKCS #1 v2.0) shall be used for SAs with the TEK encryption algorithm identifier in the cryptographic suite equal to 0x02. When the RSA algorithm is in use for TEK encryption algorithm, the TEK is encrypted with SS’s public key using the RSA algorithm. In this case, KEK is not used.

7.5.2.3 Encryption of TEK-128 with AES

This method of encrypting the TEK-128 shall be used for SAs with the TEK encryption algorithm identifier in the cryptographic suite equal to 0x03.

The BS encrypts the value fields of the TEK-128 in the Key Reply messages it sends to client SS. This field is encrypted using 128-bit AES in ECB mode.

encryption: $C = E_{k1}(P)$

decryption: $P = D_{k1}(C)$

$P =$ Plaintext 128-bit TEK

$C =$ Ciphertext 128-bit TEK

$k1 =$ the 128-bit KEK

$E[ ] =$ 128-bit AES ECB mode encryption

$D[ ] =$ 128-bit AES ECB decryption

Subclause 7.5.4 describes how the KEK is derived from the AK.

7.5.2.4 Encryption of TEK-128 with AES key wrap

This method of encrypting the TEK-128 shall be used for SAs with the TEK encryption algorithm identifier in the cryptographic suite equal to 0x04.

The BS encrypts the value fields of the TEK-128 in the Key Reply messages it sends to client SS. This field is encrypted using the AES key wrap algorithm.

encryption: $C,I = E_{k}(P)$

decryption: $P,I = D_{k}(C)$

$P =$ Plaintext 128-bit TEK

$C =$ Ciphertext 128-bit TEK

$I =$ Integrity Check Value

$k =$ the 128-bit KEK

$E_{k}[ ] =$ AES Key Wrap encryption with key $k$
\[ Dk\] = AES Key Wrap decryption with key k

The AES key wrap encryption algorithm returns both a ciphertext and an integrity check value. The decryption algorithm returns a plaintext key and the integrity check value. The default integrity check value in the NIST AES key wrap algorithm shall be used.

### 7.5.3 Calculation of HMAC-Digests

The calculation of the keyed hash in the HMAC-Digest attribute and the HMAC Tuple shall use the HMAC (IETF RFC 2104) with the secure hash algorithm SHA-1 (FIPS 180-1). The DL authentication key HMAC_KEY_D shall be used for authenticating messages in the DL direction. The UL authentication key HMAC_KEY_U shall be used for authenticating messages in the UL direction. UL and DL message authentication keys are derived from the AK (see 7.5.4 for details). The HMAC Sequence number in the HMAC Tuple shall be equal to the AK Sequence Number of the AK from which the HMAC_KEY_x was derived.

The HMAC sequence number in the HMAC tuple or Short-HMAC tuple shall be equal to the AK sequence number of the AK from which the HMAC_KEY_x was derived.

In the case of PKMv2, Short-HMAC digest calculations shall include the HMAC_PN_* that should be concatenated after the MAC management message.

### 7.5.4 Derivation of TEKs, KEKs, and message authentication keys

The BS generates AKs, TEKs, and IVs. A random or pseudo-random number generator shall be used to generate AKs and TEKs. A random or pseudo-random number generator may also be used to generate IVs. Regardless of how they are generated, IVs shall be unpredictable. Recommended practices for generating random numbers for use within cryptographic systems are provided in IETF RFC 1750 [B30]. In case of using RSA algorithm, KEK is not used.

#### 7.5.4.1 DES keys

FIPS 81 defines 56-bit DES keys as 8-byte (64-bit) quantities where the 7 MSBs (i.e., 7 leftmost bits) of each byte are the independent bits of a DES key, and the LSB (i.e., rightmost bit) of each byte is a parity bit computed on the preceding seven independent bits and adjusted so that the byte has odd parity.

PKM does not require odd parity. The PKM protocol generates and distributes 8-byte DES keys of arbitrary parity, and it requires that implementations ignore the value of the LSB of each.

#### 7.5.4.2 Key encryption keys (KEKs)

The keying material for two-key 3-DES consists of two distinct (single) DES keys.

The 3-DES KEK used to encrypt the TEK is derived from a common AK. The KEK shall be derived as follows:

\[
\text{KEK} = \text{Truncate}(\text{SHA}(\text{K_PAD\_KEK} | \text{AK}), 128) \\
\text{K_PAD\_KEK} = 0x53 \text{ repeated 64 times, i.e., a 512-bit string.}
\]

\text{Truncate}(x, y) \text{ is defined as the last } ' y ' \text{ bits of } x \text{ if and only if } y \leq x. \text{ The values } ' x ' \text{ and } ' y ' \text{ shall be aligned to byte boundaries.}

The following examples illustrate the expected output of Truncate given inputs for “x” in hexadecimal, decimal and binary:
Hex:
Truncate(0x66,0x2) = 0x2
Truncate(0x65,0x2) = 0x1

Decimal:
Truncate(102,2) = 2
Truncate(101,2) = 1

Binary:
Truncate(1100110,10) = 10
Truncate(1100101,10) = 01

SHA(x|y) denotes the result of applying the SHA-1 function to the concatenated bit strings x and y.

The keying material of 3-DES consists of two distinct DES keys. The most significant 64 bits of the KEK shall be used in the encrypt operation. The least significant 64 bits shall be used in the decrypt operation.

Example:
KEK=0xAB CD 12 34 DC BA 43 21 12 34 DC BA AB AC BC BD

Encrypt Key = 0xAB CD 12 34 DC BA 43 21, where 0xAB = 10101011, 0xCD = 11001101 and so on

Decrypt Key = 0x12 34 DC BA AB AC BC BD

The construction of the KEK for use with TEK-128 keys shall be the same as for 3-DES KEKs except that the full 128 bits of the KEK are used directly as the 128-bit AES key, instead of the KEK being split into two 64-bit DES keys.

7.5.4.3 HMAC authentication keys

The HMAC authentication keys are derived as follows:

HMAC_KEY_D = SHA(H_PAD_D|AK)
HMAC_KEY_U = SHA(H_PAD_U|AK)
HMAC_KEY_S = SHA(H_PAD_D|Operator Shared Secret)

with

H_PAD_D = 0x3A repeated 64 times
H_PAD_U = 0x5C repeated 64 times

7.5.4.4 Cipher-based message authentication code (CMAC)

A BS or SS may support management message integrity protection based on CMAC—together with the AES block cipher. The CMAC construction as specified in NIST Special Publication 800-38B shall be used.

7.5.4.4.1 Calculation of CMAC value

The calculation of the keyed hash value contained in the CMAC Digest attribute and the CMAC Tuple shall use the CMAC algorithm with AES. The DL authentication key CMAC_KEY_D shall be used for authenticating messages in the DL direction. The UL authentication key CMAC_KEY_U shall be used for
authenticating messages in the UL direction. UL and DL message authentication keys are derived from the AK (see 7.2.2.2.9 for details).

For authentication broadcast messages (in the DL only) a CMAC_KEY_GD shall be used (one for each group), group authentication key is derived from GKEK.

The CMAC Digest and CMAC Tuple attributes shall be only applicable to the PKM version 2. In the PKM version 2 protocol, the AKID used in the computation of the CMAC value shall be the 64-bit AKID of the AK from which the CMAC_KEY_x was derived. See 6.3.2.3.9.17 for the SA-TEK-Challenge message attributes in which the mapping between the AK sequence number and the AKID is communicated, and see 7.2.2.4.1 for a description of the AK context that contains the AK and AKID.

The CMAC Packet Number Counter, CMAC_PN_*, is a 4-byte sequential counter that is incremented for each MAC Management Message which contains a CMAC Tuple or CMAC Digest TLV in the context of UL messages by the SS, and in the context of DL messages by the BS. The BS shall also maintain a separate CMAC_PN_* for multicast packets per each GSA and increment that counter in the context of each multicast packet from the group. If basic CID is unknown (e.g., in network reentry situation) then CID 0 should be used.

The CMAC_PN_* is part of the CMAC security context and shall be unique for each MAC management message with the CMAC tuple or digest. Any tuple value of {CMAC_PN_*, CMAC_KEY_*} shall not be used more than once. The reauthentication process should be initiated (by BS or SS) to establish a new AK before the CMAC_PN_* reaches the end of its number space.

The digest shall be calculated over a field consisting of the AKID followed by the CMAC_PN_*, expressed as an unsigned 32-bit number, followed by the 16-bit CID on which the message is sent, followed by 16-bit of zero padding (for the header to be aligned with AES block size) and followed by the entire MAC management message with the exception of the CMAC TLV.

The LSBs of the digest shall be truncated to yield a 64-bit length digest. Note: This is different from the recommendation in NIST special publication 800-38B where the MSB is used to derive the CMAC value.

i.e., if CMAC_KEY_* is derived from AK:

\[
\text{CMAC value} \leftarrow \text{Truncate}(\text{CMAC} (\text{CMAC_KEY_*}, \text{AKID} | \text{CMAC_PN} | \text{CID}|16\text{-bit zero padding } | \text{MAC_Management_Message}), 64).
\]

If CMAC_KEY_* is derived from a key other than AK, such as GKEK or EIK, CMAC_PAD is used instead of AKID.

\[
\text{CMAC value} \leftarrow \text{Truncate}(\text{CMAC} (\text{CMAC_KEY_*}, \text{CMAC_PAD} | \text{CMAC_PN} | \text{CID}|16\text{-bit zero padding } | \text{MAC_Management_Message}), 64) \text{ with CMAC_PAD = 0x7E} \text{ repeated 8 times}
\]

If the digest is included in a MAC PDU that has no CID, e.g., A RNG-REQ message, the CID used shall take the value of the basic CID. If basic CID is unknown (e.g., in network reentry situation) then CID 0 should be used.

### 7.5.4.5 Derivation of TEKs, KEKs, message authentication keys and GKEKs in PKMv2

#### 7.5.4.5.1 AES KEKs in PKMv2

The construction of the KEK for use with TEK-128 keys shall be the same as for 3-DES KEKs as described in 7.5.4.2 except that the full 128 bits of the KEK are used directly as the 128-bit AES key, instead of the KEK being split into two 64-bit DES keys.
7.5.4.5.2 Encryption of GKEK in PKMv2

The BS encrypts the value fields of the GKEK in the PKMv2 Group-Key-Update-Command message for the GKEK update mode and sends the encrypted GKEK to each SS served with the specific multicast service or the broadcast service. The following options for encryption of GKEK may be used. The encryption algorithm is determined according to the value of cryptographic suite. Also, the value of cryptographic suite for GKEK encryption is identical to the one for GTEK encryption.

7.5.4.5.2.1 Encryption of GKEK with 3-DES in PKMv2

This method of encrypting the GKEK shall be used for SAs with the TEK (or GTEK) encryption algorithm identifier in the cryptographic suite equal to 0x01.

The BS encrypts the value fields of the GKEK in the Key Update Command messages (for the GKEK update mode) it sends to client SS. This field is encrypted using two-key 3-DES in the EDE mode.

Encryption: \( C = E_{k1}(D_{k2}(E_{k1}(P))) \)
Decryption: \( P = D_{k1}(E_{k2}(D_{k1}(C))) \)

\( P = \) Plaintext 128-bit GKEK
\( C = \) Ciphertext 128-bit GKEK
\( k1 = \) most significant 64 bits of the 128-bit KEK
\( k2 = \) least significant 64 bits of the 128-bit KEK
\( E \ [ \ ] = \) 56-bit DES ECB mode encryption
\( D \ [ \ ] = \) 56-bit DES ECB mode decryption

7.5.4.5.2.2 Encryption of GKEK with RSA in PKMv2

The RSA method of encrypting the GKEK (PKCS #1 v2.1, RSA Cryptography Standard, RSA Laboratories, June 2002) shall be used for SAs with the TEK (or GTEK) encryption algorithm identifier in the cryptographic suite equal to 0x02.

7.5.4.5.2.3 Encryption of GKEK with ECB mode AES in PKMv2

This method of encrypting the GKEK shall be used for SAs with the TEK (or GTEK) encryption algorithm identifier in the cryptographic suite equal to 0x03.

The BS encrypts the value fields of the GKEK in the PKMv2 Group-Key-Update-Command messages (for the GKEK update mode) it sends to client SS. This field is encrypted using 128-bit AES in ECB mode.

Encryption: \( C = E_{k1}(P) \)
Decryption: \( P = D_{k1}(C) \)

\( P = \) Plaintext 128-bit GKEK
\( C = \) Ciphertext 128-bit GKEK
\( k1 = \) the 128-bit KEK
\( E \ [ \ ] = 128\text{-bit AES ECB mode encryption} \)
\( D \ [ \ ] = 128\text{-bit AES ECB mode decryption} \)

7.5.4.5.2.4 Encryption of GKEK with AES key wrap in PKMv2

This method of encrypting the GKEK shall be used for SAs with the TEK (or GTEK) encryption algorithm identifier in the cryptographic suite equal to 0x04.
The BS encrypts the value fields of the GKEK in the PKMv2 Group-Key-Update-Command messages (for the GKEK update mode) it sends to client SS. This field is encrypted using 128-bit AES key wrap algorithm. This 128-bit AES key wrap algorithm is defined only for PKM version 2.

Encryption: $C, I = E_k[P]$
Decryption: $P, I = D_k[C]$
$P =$ Plaintext 128-bit GKEK
$C =$ Ciphertext 128-bit GKEK
$k =$ the 128-bit KEK derived from the AK
$E_k[ ] =$ AES Key Wrap encryption with key $k$
$D_k[ ] =$ AES Key Wrap decryption with key $k$

7.5.4.6 Key derivation functions for PKMv2

7.5.4.6.1 Dot16KDF for PKMv2

The Dot16KDF algorithm is a CTR mode construction that may be used to derive an arbitrary amount of keying material from source keying material.

In the case that the HMAC/CMAC setting in the message authentication code mode is set to CMAC, the algorithm is defined as follows:

```c
Dot16KDF(key, astring, keylength)
{
    result = null;
    Kin = Truncate (key, 128);
    for (i = 0; i <= int((keylength-1)/128); i++) {
        result = result | CMAC(Kin, i | astring | keylength);
    }
    return Truncate (result, keylength);
}
```

In the case that the HMAC/CMAC setting in the authentication policy bits is set to HMAC, the algorithm is defined as follows:

```c
Dot16KDF(key, astring, keylength)
{
    result = null;
    Kin = Truncate (key, 160);
    For (i=0; i <= int( (keylength-1)/160 ); i++) {
        result = result | SHA-1( i | astring | keylength | Kin);
    }
    return Truncate (result, keylength);
}
```

When CMAC algorithm is used, the size of the variables ‘i’ is 4 octets (32 bits) in most-significant-bit first order. ‘astring’ is a character string. For example, if ‘astring’ is ‘test’, then ‘astring’ is: 0x74657374 (no null-termination). The size of ‘keylength’ field is 4 octets (32 bits) in most-significant-bit first order.

The key is a cryptographic key that is used by the underlying digest algorithm (SHA-1 or CMAC-AES). astring is an octet string used to alter the output of the algorithm. keylength is used to determine the length of key material to generate and is used in the digest input data to prevent extension attacks. The Truncate() function is defined in 7.5.4.2.
7.5.5 Public-key encryption of AK

AKs in Auth Reply messages shall be RSA public-key encrypted, using the SS’s public key. The protocol uses 65537 (0x010001) as its public exponent and a modulus length of 1024 bits. The PKM protocol employs the RSAES-OAEP encryption scheme (PKCS #1). RSAES-OAEP requires the selection of a hash function, a mask-generation function, and an encoding parameter string. The default selections specified in PKCS #1 shall be used when encrypting the AK. These default selections are SHA-1 for the hash function, MGF1 with SHA-1 for the mask-generation function, and the empty string for the encoding parameter string.

7.5.6 Digital signatures

The Protocol employs the RSA Signature Algorithm (PKCS #1) with SHA-1 (FIPS 186-2) for both of its certificate types.

As with its RSA encryption keys, Privacy uses 65537 (0x010001) as the public exponent for its signing operation. Manufacturer CAs shall employ signature key modulus lengths of at least 1024 bits and no greater than 2048 bits.

7.6 Certificate profile

7.6.1 Certificate format

This subclause describes the X.509 (IETF RFC 2459) Version 3 certificate format and certificate extensions used in IEEE 802.16 compliant SSs. Table 210 summarizes the basic fields of an X.509 Version 3 certificate.

<table>
<thead>
<tr>
<th>X.509 v3 field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbsCertificate.version</td>
<td>Indicates the X.509 certificate version. Always set to v3 (value of 2).</td>
</tr>
<tr>
<td>tbsCertificate.serialNumber</td>
<td>Unique integer the issuing CA assigns to the certificate.</td>
</tr>
<tr>
<td>tbsCertificate.signature</td>
<td>Object identifier (OID) and optional parameters defining algorithm used to sign the certificate. This field shall contain the same algorithm identifier as the signatureAlgorithm field.</td>
</tr>
<tr>
<td>tbsCertificate.issuer</td>
<td>Distinguished Name of the CA that issued the certificate.</td>
</tr>
<tr>
<td>tbsCertificate.validity</td>
<td>Specifies when the certificate becomes active and when it expires.</td>
</tr>
<tr>
<td>tbsCertificate.subject</td>
<td>Distinguished Name identifying the entity whose public key is certified in the subjectpublic key information field.</td>
</tr>
<tr>
<td>tbsCertificate.subjectPublicKeyInfo</td>
<td>Field contains the public key material (public key and parameters) and the identifier of the algorithm with which the key is used.</td>
</tr>
<tr>
<td>tbsCertificate.issuerUniqueID</td>
<td>Optional field to allow reuse of issuer names over time.</td>
</tr>
<tr>
<td>tbsCertificate.subjectUnique ID</td>
<td>Optional field to allow reuse of subject names over time.</td>
</tr>
<tr>
<td>tbsCertificate.extensions</td>
<td>The extension data.</td>
</tr>
</tbody>
</table>
Table 210—Basic fields of an X.509 Version 3 certificate (continued)

<table>
<thead>
<tr>
<th>X.509 v3 field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>signatureAlgorithm</td>
<td>OID and optional parameters defining algorithm used to sign the certificate.</td>
</tr>
<tr>
<td></td>
<td>This field shall contain the same algorithm identifier as the signature field in tbsCertificate.</td>
</tr>
<tr>
<td>signatureValue</td>
<td>Digital signature computed upon the ASN.1 DER encoded tbsCertificate.</td>
</tr>
</tbody>
</table>

All certificates described in this specification shall be signed with the RSA signature algorithm using SHA-1 as the one-way hash function. The RSA signature algorithm is described in PKCS #1; SHA-1 is described in FIPS 180-1. Restrictions posed on the certificate values are described in 7.6.1.1 through 7.6.1.8.

7.6.1.1 tbsCertificate.validity.notBefore and tbsCertificate.validity.notAfter

SS certificates shall not be renewable and shall thus have a validity period greater than the operational lifetime of the SS. A Manufacturer CA certificate’s validity period should exceed that of the SS certificates it issues. The validity period of an SS certificate shall begin with the date of generation of the device’s certificate; the validity period should extend out to at least 10 years after that manufacturing date. Validity periods shall be encoded as UTCTime. UTCTime values shall be expressed Greenwich Mean Time (Zulu) and shall include seconds (i.e., times are YYMMDDHHMMSSZ), even where the number of seconds is zero.

7.6.1.2 tbsCertificate.serialNumber

Serial numbers for SS certificates signed by a particular issuer shall be assigned by the manufacturer in increasing order. Thus, if the tbsCertificate.validity.notBefore field of one certificate is greater than the tbsCertificate.validity.notBefore field of another certificate, then the serial number of the first certificate shall be greater than the serial number of the second certificate.

7.6.1.3 tbsCertificate.signature and signatureAlgorithm

All certificates described in this specification shall be signed with the RSA signature algorithm, using SHA-1 as the one-way hash function. The RSA signature algorithm is described in PKCS #1; SHA-1 is described in FIPS 180-1. The ASN.1 OID used to identify the “SHA-1 with RSA” signature algorithm is

```
sha-1WithRSAEncryption OBJECT IDENTIFIER ::=  
{ iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1) pkcs-1(1) 5}
```

When the sha-1WithRSAEncryption OID appears within the ASN.1 type AlgorithmIdentifier, as is the case with both tbsCertificate.signature and signatureAlgorithm, the parameters component of that type is the ASN.1 type NULL.

7.6.1.4 tbsCertificate.issuer and tbsCertificate.subject

X.509 Names are SEQUENCES of RelativeDistinguishedNames, which are in turn SETs of AttributeTypeAndValue. AttributeTypeAndValue is a SEQUENCE of an AttributeType (an OBJECT IDENTIFIER) and an AttributeValue. The value of the countryName attribute shall be a two-character PrintableString, chosen from ISO 3166; all other AttributeValues shall be encoded as either
T.61/TeletexString or PrintableString character strings. The PrintableString encoding shall be used if the character string contains only characters from the PrintableString set. Specifically:

```
abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQRSTUVWXYZ
0123456789
'+-,./:=? and space
```

The T.61/TeletexString shall be used if the character string contains other characters. The following OIDs are needed for defining issuer and subject Names in PKM certificates:

```
id-at OBJECT IDENTIFIER ::= {joint-iso-ccitt(2) ds(5) 4}
id-at-commonName OBJECT IDENTIFIER ::= {id-at 3}
id-at-countryName OBJECT IDENTIFIER ::= {id-at 6}
id-at-localityName OBJECT IDENTIFIER ::= {id-at 7}
id-at-stateOrProvinceName OBJECT IDENTIFIER ::= {id-at 8}
id-at-organizationName OBJECT IDENTIFIER ::= {id-at 10}
id-at-organizationalUnitName OBJECT IDENTIFIER ::= {id-at 11}
```

The following subclauses describe the attributes that comprise the subject Name forms for each type of PKM certificate. Note that the issuer name form is the same as the subject of the issuing certificate. Additional attribute values that are present but unspecified in the following forms should not cause a device to reject the certificate.

**7.6.1.4.1 Manufacturer certificate**

```
countryName=<Country of Manufacturer>
[stateOrProvinceName=<state/province>]
[localityName=<City>]
organizationName=<Company Name>
organizationalUnitName=WirelessMAN
[organizationalUnitName=<Manufacturing Location>]
commonName=<Company Name> <Certification Authority>
```

The countryName, organizationName, and commonName attributes shall be included and shall have the values shown. The organizationalUnitName having the value “WirelessMAN” shall be included. The organizationalUnitName representing manufacturing location should be included. If included, it shall be preceded by the organizationalUnitName having value “WirelessMAN.” The stateOrProvinceName and localityName may be included. Other attributes are not allowed and shall not be included.

**7.6.1.4.2 SS certificate**

```
countryName=<Country of Manufacturer>
organizationName=<Company Name>
organizationalUnitName=<manufacturing location>
commonName=<Serial Number>
commonName=<MAC Address>
```

The MAC address shall be the SS’s MAC address. It is expressed as six pairs of hexadecimal digits separated by colons (:), e.g., “00:60:21:A5:0A:23.” The Alpha HEX characters (A–F) shall be expressed as uppercase letters.

The organizationalUnitName in an SS certificate, which describes the modem’s manufacturing location, should be the same as the organizationalUnitName in the issuer Name describing a manufacturing location.
The countryName, organizationName, organizationalUnitName, and commonName attributes shall be included. Other attributes are not allowed and shall not be included.

7.6.1.4.3 BS certificate

```
countryName=<Country of Operation>
organizationName=<Name of Infrastructure Operator>
organizationalUnitName=<WirelessMAN>
commonName=<Serial Number>
commonName=<BSID>
```

The BSID field shall contain the operator-defined BSID. It is expressed as six pairs of hexadecimal digits separated by colons (:), e.g., "00:60:21:A5:0A:23." The Alpha HEX characters (A–F) shall be expressed as uppercase letters.

The attributes listed above shall be included.

7.6.1.5 tbsCertificate.subjectPublicKeyInfo

The tbsCertificate.subjectPublicKeyInfo field contains the public key and the public key algorithm identifier. The tbsCertificate.subjectPublicKeyInfo.algorithm field is an AlgorithmIdentifier structure. The AlgorithmIdentifier’s algorithm shall be RSA encryption, identified by the following OID:

```
pkcs-1 OBJECT IDENTIFIER ::= { iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1) 1}
rsaEncryption OBJECT IDENTIFIER ::= { pkcs-1 1}
```

The AlgorithmIdentifier’s parameters field shall have ASN.1 type NULL. The RSA public key shall be encoded using the ASN.1 type RSAPublicKey:

```
RSAPublicKey ::= SEQUENCE {
  modulus INTEGER, -- n
  publicExponent INTEGER, -- e -- }
```

where modulus is the modulus \( n \), and publicExponent is the public exponent \( e \). The DER encoded RSAPublicKey is the value of the BIT STRING tbsCertificate.subjectPublicKeyInfo.subjectPublicKey.

7.6.1.6 tbsCertificate.issuerUniqueID and tbsCertificate.subjectUniqueID

The issuerUniqueID and subjectUniqueID fields shall be omitted for all of the PKM’s certificate types.

7.6.1.7 tbsCertificate.extensions

7.6.1.7.1 SS certificates

SS certificates may contain noncritical extensions; they shall not contain critical extensions. If the KeyUsage extension is present, the keyAgreement and keyEncipherment bits shall be turned on, keyCertSign and cRLSign bits shall be turned off, and all other bits should be turned off.

---

23 The BSID is an operator-defined value, consequently the BS certificate is typically issued by the Operator, who must ensure that the BS ID is unique within the operator’s network.
7.6.1.7.2 Manufacturer certificates

Manufacturer certificates may contain the Basic Constraints extension. If included, the Basic Constraints extension may appear as a critical extension or as a noncritical extension. Manufacturer certificates may contain noncritical extensions; they shall not contain critical extensions other than, possibly, the Basic Constraints extension. If the KeyUsage extension is present in a Manufacturer certificate, the keyCertSign bit shall be turned on and all other bits should be turned off.

7.6.1.8 signatureValue

In all three PKM certificate types, the signatureValue contains the RSA (with SHA-1) signature computed over the ASN.1 DER encoded tbsCertificate. The ASN.1 DER encoded tbsCertificate is used as input to the RSA signature function. The resulting signature value is ASN.1 encoded as a bit string and included in the Certificate’s signatureValue field.

7.6.2 SS certificate storage and management in the SS

Manufacturer-issued SS certificates shall be stored in SS permanent, write-once memory. SSs that have factory-installed RSA private/public key pairs shall also have factory-installed SS certificates. SSs that rely on internal algorithms to generate an RSA key pair shall support a mechanism for installing a manufacturer-issued SS certificate following key generation. The CA certificate of the Manufacturer CA that signed the SS certificate shall be embedded into the SS software. If a manufacturer issues SS certificates with multiple Manufacturer CA certificates, the SS software shall include ALL of that manufacturer’s CA certificates. The specific Manufacturer CA certificate installed by the SS [i.e., advertised in Authentication Information messages and returned by the management information base (MIB) object] shall be that identifying the issuer of that modem’s SS certificate.

7.6.3 Certificate processing and management in the BS

PKM employs digital certificates to allow BSs to verify the binding between an SS’s identity (encoded in an X.509 digital certificate’s subject names) and its public key. The BS does this by validating the SS certificate’s certification path or chain. Validating the chain means verifying the Manufacturer CA Certificate through some means.

7.7 Preauthentication

In anticipation of an HO, an MS may seek to use preauthentication to facilitate an accelerated reentry at a particular target BS.

Preauthentication results in establishment of an AK (with a unique AK name) in the MS and target BS. The specific mechanism for preauthentication is out of the scope of this specification.

7.8 PKMv2

7.8.1 PKMv2 SA-TEK 3-way handshake

The AK can be derived in one of three different ways depending on the authentication scheme used as documented in 7.2.2.2.3. Before the 3-way handshake begins, the BS and SS shall both derive a shared KEK and HMAC/CMAC keys as per 7.2.2.2.

The PKMv2 SA-TEK 3-way handshake sequence proceeds as follows:
a) During initial network entry or reauthorization, the BS shall send PKMv2 SA-TEK-Challenge (including a random number BS_Random) to the SS after protecting it with the HMAC/CMAC Tuple. If the BS does not receive PKMv2 SA-TEK-Request from the SS within SACHallengeTimer, it shall resend the previous PKMv2 SA-TEK-Challenge up to SACHallengeMaxResends times. If the BS reaches its maximum number of resends, it shall: initiate another full authentication or drop the SS. If SS had been in the midst of an EAP exchange and had been awaiting notification of completion of the exchange through PKMv2 EAP Transfer with EAP-Success, or PKMv2 Authenticated EAP Transfer with EAP-Success, and the SS instead receives SA-TEK-Challenge signed with a CMAC derived from the new key material then the SS shall first treat the SA-TEK-Challenge as receipt of PKMv2 EAP Transfer with EAP-Success, or PKMv2 Authenticated EAP Transfer with EAP-Success, and then the SS shall process the SA-TEK-Challenge as if it had received the message after normally receiving the preceding PKMv2 EAP Transfer with EAP-Success, or PKMv2 Authenticated EAP Transfer with EAP-Success.

b) If HO Process Optimization Bit 1 is set to 1 indicating that PKM Authentication phase is omitted and HO Process Optimization Bit 2 is set to 0 during network re-entry or handover, the BS updates TEKs by appending the SA-TEK-Update TLV to RNG-RSP message.

c) The SS shall send PKMv2 SA-TEK-Request to the BS after protecting it with the HMAC/CMAC. If the SS does not receive PKMv2 SA-TEK-Response from the BS within SATEKTimer, it shall resend the request. The SS may resend the PKMv2 SA-TEK-Request up to SATEKRequestMaxResends times. If the SS reaches its maximum number of resends, it shall initiate another full authentication or attempt to connect to another BS. The SS shall include, through the Security Negotiation Parameters attribute, the security capabilities that it included in the SBC-REQ message during the basic capabilities negotiation phase.

d) Upon receipt of PKMv2 SA-TEK-Request, a BS shall confirm that the supplied AKID refers to an AK that it has available. If the AKID is unrecognized, the BS shall ignore the message. The BS shall verify the HMAC/CMAC. If the HMAC/CMAC is invalid, the BS shall ignore the message. The BS shall verify that the BS_Random in the SA TEK Request matches the value provided by the BS in the SA Challenge message. If the BS_Random value does not match, the BS shall ignore the message. In addition, the BS shall verify the SS’s security capabilities encoded in the Security Negotiation Parameters attribute against the security capabilities provided by the SS through the SBC-REQ message. If security negotiation parameters do not match, the BS should report the discrepancy to higher layers.

e) Upon successful validation of the PKMv2 SA-TEK-Request, the BS shall send PKMv2 SA-TEK-Response back to the SS. The message shall include a compound TLV list each of which identifies the Primary and static SAs, their SA identifiers (SAID) and additional properties of the SA (e.g., type, cryptographic suite) that the SS is authorized to access. After the MS has received the SA-TEK-Response message and verified the authenticity of the message the MS shall start using the new AK context for all UL management messages. The MS shall maintain the old context and use it to validate messages received from the BS using this AK context for as long as the frame number included in the SA-TEK-Response message has not been reached. The BS shall continue using the old AK context until it receives a management message from the MS using the new AK context, after which it shall start using the new AK context for DL management messages. Regardless of having received any UL message authenticated using the new AK context, the BS shall discard the old context upon reaching the frame number included in the last SA-TEK-Response message sent to the MS. At this point in time the 3-way handshake is considered to have successfully completed. In case of HO, the details of any Dynamic SAs that the requesting MS was authorized in the previous serving BS are also included. In addition, the BS shall include, through the Security Negotiation Parameters attribute, the security capabilities that it wishes to specify for the session with the SS (these will generally be the same as the ones insecurely negotiated in SBC-REQ/RSP).

Additionally, in case of HO, for each active SA in previous serving BS, corresponding TEK, GTEK and GKEK parameters are also included. Thus, SA_TEK_Update provides a shorthand method for renewing active SAs used by the MS in its previous serving BS. The TLVs specify SAID in the
target BS that shall replace active SAID used in the previous serving BS and also “older” TEK-Parameters and “newer” TEK-Parameters relevant to the active SAIDs. The update may also include multicast/broadcast Group SAIDs (GSAIDs) and associated GTEK-Parameters pairs.

In case of unicast SAs, the TEK-Parameters attribute contains all of the keying material corresponding to a particular generation of an SAID’s TEK. This would include the TEK, the TEK’s remaining key lifetime, its key sequence number and the CBC IV. The TEKs are encrypted with KEK.

In case of group or multicast SAs, the TEK-Parameters attribute contains all of the keying material corresponding to a particular generation of a GSAID’s GTEK. This would include the GTEK, the GTEK’s remaining key lifetime, the GTEK’s key sequence number, the associated GKEK sequence number and the cipher block chaining (CBC) initialization vector. The type and length of the GTEK is equal to corresponding values of the TEK. The GKEK should be identically shared within the same multicast group or the MBS group. Unlike the PKMv2 Group-Key-Update-Command, the GTEKs and GKEKs are encrypted with the negotiated TEK encryption algorithm because they are transmitted as unicast messages. This GKEK-Parameters compound TLV includes the GKEK, the GKEK’s remaining lifetime and the GKEK sequence number.

Multiple iterations of these TLVs may occur suitable to re-creating and reassigning all active SAs and their (G)TEK pairs for the SS from its previous serving BS. If any of the Security Associations parameters change, then those Security Associations parameters encoding TLVs that have changed shall be added.

The HMAC/CMAC shall be the final attribute in the message’s attribute list.

f) Upon receipt of PKMv2 SA-TEK-Response, an SS shall verify the HMAC/CMAC. If the HMAC/CMAC is invalid, the SS shall ignore the message. Upon successful validation of the received PKMv2 SA-TEK-Response, the SS shall install the received TEKs and associated parameters appropriately. Verification of HMAC/CMAC is done as per subclauses 7.5.3 and 7.5.4.4.

The SS also shall verify the BS’s security negotiation parameters TLV encoded in the Security Negotiation Parameters attribute against the security negotiation parameters TLV provided by the BS through the SBC-RSP message. If security capabilities do not match, the SS should report the discrepancy to upper layers. The SS may choose to continue the communication with the BS. In this case, the SS may adopt the security negotiation parameters encoded in SA-TEK-Response message. After the MS has received the SA-TEK-Response message and verified the authenticity of the message the MS shall start using the new AK context for all UL management messages. The MS shall maintain the old context and use it to validate messages received from the BS using this AK context for as long as the frame number included in the SA-TEK-Response message has not been reached. The BS shall continue using the old AK context until it receives a management message from the MS using the new AK context, after which it shall start using the new AK context for DL management messages. Regardless of having received any UL message authenticated using the new AK context, the BS shall discard the old context upon reaching the frame number included in the last SA-TEK-Response message sent to the MS. At this point in time the 3-way handshake is considered to have successfully completed.

7.8.2 BS and SS RSA mutual authentication and AK exchange overview

The BS mutual authentication can take place in one of two modes of operation. In one mode, only mutual authentication is used. In the other mode, the mutual authentication is followed by EAP authentication. In this second mode, the mutual authentication is performed only for initial network entry and only EAP authentication is performed in the case that authentication is needed in reentry.

SS mutual authorization, controlled by the PKMv2 Authorization state machine, is the process of

a) The BS authenticating a client SS’s identity.

b) The SS authenticating the BS’s identity.
c) The BS providing the authenticated SS with an AK, from which a KEK and message authentication keys are derived.

d) The BS providing the authenticated SS with the identities (i.e., the SAIDs) and properties of primary and static SAs the SS is authorized to obtain keying information for.

After achieving initial authorization, an SS periodically seeks reauthorization with the BS; reauthorization is also managed by the SS’s PKMv2 Authorization state machine. An SS shall maintain its authorization status with the BS in order to be able to refresh aging TEKs and GTEKs. TEK state machines manage the refreshing of TEKs. The SS or BS may run optional authenticated EAP messages for additional authentication.

The SS sends an Authorization Request message to its BS immediately after sending the Authentication Information message. This is a request for an AK, as well as for the SAIDs identifying any Static Security SAs the SS is authorized to participate in. The Authorization Request includes (see 6.3.2.3.9.19)

- A manufacturer-issued X.509 certificate.
- A description of the cryptographic algorithms the requesting SS supports; an SS’s cryptographic capabilities are presented to the BS as a list of cryptographic suite identifiers, each indicating a particular pairing of packet data encryption and packet data authentication algorithms the SS supports.
- The SS’s Basic CID. The Basic CID is the first static CID the BS assigns to an SS during initial ranging—the primary SAID is equal to the Basic CID.
- A 64-bit random number generated in the SS.

In response to an Authorization Request message, a BS validates the requesting SS’s identity, determines the encryption algorithm and protocol support it shares with the SS, activates an AK for the SS, encrypts it with the SS’s public key, and sends it back to the SS in an Authorization Reply message. Random numbers are included in the exchange to ensure liveness. The Authorization Reply includes (see 6.3.2.3.9.20)

- The BS’s X.509 certificate, used to verify the BS’s identity.
- A pre-PAK encrypted with the SS’s public key.
- A 4-bit PAK sequence number, used to distinguish between successive generations of AKs.
- A PAK lifetime.
- The identities (i.e., the SAIDs) and properties of the single primary and zero or more static SAs for which the SS is authorized to obtain keying information.
- The 64-bit random number generated in the SS.
- A 64-bit random number generated in the BS, used to ensure key of liveness along with the random number of SS.
- The RSA signature over all the other attributes in the auth-reply message by BS, used to assure the the authenticity of the above PKMv2 RSA-Reply messages.

An SS shall periodically refresh its AK by reissuing an Authorization Request to the BS. Reauthorization is identical to authorization. To avoid service interruptions during reauthorization, successive generations of the SS’s AKs have overlapping lifetimes. Both SS and BS shall be able to support up to two simultaneously active AKs during these transition periods. The operation of the Authorization state machine’s Authorization Request scheduling algorithm, combined with the BS’s regimen for updating and using a client SS’s AKs (see 7.4), ensures that the SS can refresh TEK keying information without interruption over the course of the SS’s reauthorization periods.

After successful RSA based authorization either EAP based authorization or Authenticated EAP based authorization maybe supported according to the value of Authorization policy negotiated in the SBC-REQ/RSP messages. It shall cryptographically bind RSA and further EAP authentication.
7.8.3 Multicast and broadcast service (MBS) support

MBS is an efficient and power saving mechanism that requires PKMv2 to send multimedia broadcast information. It provides subscribers with strong protection from theft of service across broadband wireless mobile network by encrypting broadcast connections between SSs and BSs.

7.8.3.1 MBS security associations

In addition to existing three Security Association, MBS requires a MBS Group Security Association. It is the set of security information that multiple BS and one or more of its client SSs share but not bound to any MS authorization state in order to support secure and access controlled MBS content reception across the IEEE 802.16 network. Each MBS capable MS may establish a MBS security association during the MS initialization process. MBS GSAs shall be provisioned within the BS. A MBS GSA's shared information shall include the cryptographic suite employed within the GSA and key material information such as MBS authorization keys (MAKs) and MBS group traffic encryption keys (MGTEKs). The exact content of the MGSA is dependent on the MGSA's cryptographic suite. As like any other Unicas t SAs, MBS GSA is also identified using 16 bit SAIDs. Each MS shall establish one or more MBS GSA with its serving BS.

Using the PKMv2 protocol, an MS receives or establishes an MBS GSA's keying material. The BS and MBS content server shall ensure that each client MS only has access to the MGsAs it is authorized to access.

An SA's keying material (e.g., MAK and MGTEK) has a limited lifetime. When the MBS content server or BS delivers MBS SA keying material to an MS, it also provides the MS with that material’s remaining lifetime. It is the responsibility of the MS to request new keying material from the MBS server or BS before the set of keying material that the MS currently holds expires at the MBS Server or BS.

7.8.3.2 MBS key management

7.8.3.2.1 MAK establishment

The MAK establishment procedure in MS and BS is outside of scope of this specification.

7.8.3.2.2 MGTEK establishment

See 7.2.2.3.3 for MBSGSA and 7.2.2.2 for PKMv2 key derivation.

7.8.3.2.3 MTK establishment

See 7.2.2.2 for PKMv2 key derivation.

7.9 Multicast and broadcast rekeying algorithm (MBRA)

When MBRA is supported, the MBRA shall be used to refresh traffic keying material efficiently not for the unicast service, but for the multicast service, the broadcast service or the MBS.
7.9.1 MBRA flow

The MBRA overall flow is shown in the Figure 176.

Figure 176—MBRA management
An SS may get the traffic keying material before an SS is served with the specific multicast service, the broadcast service or the MBS. The initial GTEK request exchange procedure is executed by using the PKMv2 Key Request and PKMv2 Key Reply messages that are carried on the Primary Management connection. The GTEK (Group Traffic Encryption Key) is the TEK for multicast or broadcast service. Once an SS shares the traffic keying material with a BS, an SS does not need to request the new traffic keying material. A BS updates and distributes the traffic keying material periodically by sending two PKMv2 Group-Key-Update-Command messages.

A BS manages the M&B (Multicast & Broadcast) TEK Grace Time for the respective GSA-ID in itself. The GSA-ID (Group Security Association Identifier) is the SA-ID for multicast, broadcast service or the MBS. This M&B TEK Grace Time is defined only for the multicast service or the broadcast service. This parameter means time interval (in seconds), before the estimated expiration of an old distributed GTEK. In addition, the M&B TEK Grace Time is longer than the TEK Grace Time managed in an SS.

A BS distributes updated traffic keying material by sending two PKMv2 Group-Key-Update-Command messages before old distributed GTEK is expired. The usage type of these messages is distinguished according to the Key Push Modes included in the PKMv2 Group-Key-Update-Command message.

A BS transmits the PKMv2 Group-Key-Update-Command message for the GKEK update mode in order to distribute the new GKEK. Moreover, a BS transmits the PKMv2 Group-Key-Update-Command message for the GTEK update mode in order to distribute the new GTEK.

In general, the GKEK lifetime corresponds to the $n$ (integer being bigger than 1) times of the GTEK lifetime. That is, the GKEK shall be updated once while the GTEK is updated $n$ times.

A BS transmits the PKMv2 Group-Key-Update-Command message for the GKEK update mode to each SS served with the specific multicast service, the broadcast service or the MBS before the current GKEK expires and the last M&B TEK Grace Time of the corresponding current GKEK starts. The purpose of the PKMv2 Group-Key-Update-Command message for the GKEK update mode is to distribute the GKEK (Group Key Encryption Key). The PKMv2 Group-Key-Update-Command message for the GKEK update mode is carried on the Primary Management connection. A BS intermittently transmits the PKMv2 Group-Key-Update-Command message for the GKEK update mode to each SS in order to reduce the BS’s load in refreshing traffic key material. The GKEK is needed to encrypt the new GTEK. The GKEK may be randomly generated in a BS or a network entity (i.e., an ASA server or an MBS server).

A BS transmits the PKMv2 Group-Key-Update-Command message for the GTEK update mode carried on the broadcast connection after each M&B TEK Grace Time starts. The aim of the PKMv2 Group-Key-Update-Command message for the GTEK update mode is to distribute new GTEK and the other traffic keying material to all SSs served with the specific multicast service or the broadcast service. This GTEK is randomly generated in the same node which generates the GKEK and encrypted with already transmitted GKEK.

An SS shall be capable of maintaining two successive sets of traffic keying material per authorized GSA-ID. Through operation of its GTEK state machines, an SS shall check whether it receives new traffic keying material or not. If an SS gets new traffic keying material, then its TEK Grace Time is not operated. However, if it does not have that, then an SS shall request a new set of traffic keying material at a configurable amount of time, the TEK Grace Time, before the SS’s latest GTEK is scheduled to expire.

If an SS receives the valid two PKMv2 Group-Key-Update-Command messages and shares new valid GKEK and GTEK with a BS, then that SS does not need to request a new set of traffic keying material.

If an SS does not receive at least one of two PKMv2 Group-Key-Update-Command messages, then that SS sends the Key Request message to get a new traffic keying material. A BS responds to the PKMv2 Key
Request message with the PKMv2 Key Reply message. In other words, if an SS does not get valid new GKEK or GTEK, then the GTEK request exchange procedure initiated by an SS shall be performed.

### 7.9.1.1 BS usage of GTEK

An SS tries to get the GTEK before an SS is served with the specific service. The initial GTEK request exchange procedure is executed by using the PKMv2 Key Request and PKMv2 Key Reply messages that are carried on the primary management connection.

A BS shall be capable of maintaining two successive sets of traffic keying material per authorized GSAID. In other words, when GKEK has been changed, a BS manages the M&B TEK Grace Time for the respective GSA-ID in itself. Through operation of its M&B TEK Grace Time, a BS shall push a new set of traffic keying material. This M&B TEK Grace Time is defined only for the multicast service or the broadcast service in a BS. This parameter means time interval (in seconds) before the estimated expiration of an old distributed GTEK. In other words, the M&B TEK Grace Time is longer than the TEK Grace Time managed in an SS.

A BS distributes updated GTEK by using two PKMv2 Group-Key-Update-Command messages when the current GKEK is about to expire, or by using PKMv2 Group-Key-Update-Command message for the GTEK update mode after the M&B TEK Grace Time starts and before the current GTEK expires. Those messages are distinguished according to a parameter included in that message, “Key Push Modes.”

A BS transmits the PKMv2 Group-Key-Update-Command message for the GKEK update mode to each SS served with the specific service before the current GKEK expires and the last M&B TEK Grace Time of the corresponding current GKEK starts. The PKMv2 Group-Key-Update-Command message for the GKEK update mode is carried on the primary management connection. A BS intermittently transmits the PKMv2 Group-Key-Update-Command message for the GKEK update mode to each SS in order to reduce the BS’s load for key refreshment. The purpose of the first PKMv2 Group-Key-Update-Command message for the GKEK update mode is to distribute the GKEK (Group Key Encryption Key). This GKEK is needed to encrypt the updated GTEK. The GKEK is also encrypted with the SS’s KEK. The GKEK may be randomly generated in a BS or a network entity (i.e., an ASA server or an MBS server).

A BS transmits the PKMv2 Group Key Update Command message for the GTEK update mode carried on the broadcast connection after the M&B TEK Grace Time. The aim of the PKMv2 Group-Key-Update-Command message for the GTEK update mode is to distribute the GTEK to the specific service group. This GTEK is encrypted with the GKEK identified by the associated GKEK sequence number. The associated GKEK sequence number is included in the GTEK-Parameters attribute.

### 7.9.1.2 SS usage of GTEK

An SS shall be also capable of maintaining two successive sets of traffic keying material per authorized GSAID. Through operation of its GTEK state machines, an SS shall check whether it receives new traffic keying material or not. If an SS get new traffic keying material, then its TEK Grace Time is not operated. However, if it does not have that, then an SS shall request a new set of traffic keying material at a configurable amount of time, the TEK Grace Time, before the SS’s latest GTEK is scheduled to expire.

### 7.9.2 Messages

Messages used in the MBRA are the PKMv2 Key Request, PKMv2 Key Reply and PKMv2 Group-Key-Update-Command messages.

— *PKMv2 Key-Request*. An SS may request the traffic keying material with the PKMv2 Key Request message in the initial GTEK request exchange procedure or the GTEK refresh procedure. Refer to 6.3.2.3.9.20.
— **PKMv2 Key-Reply.** A BS responds to the PKMv2 Key-Reply message with the Key Reply message including the traffic keying material. The PKMv2 Key-Reply message includes GKEK as well as GTEK. The GTEK is the TEK for the multicast or broadcast service. GKEK and GTEK are encrypted to safely distribute to an SS. GTEK is encrypted with the GKEK for the multicast service or the broadcast service. The GKEK is encrypted with the KEK. See 7.5.4.5.2 and 7.9.3 for details. This message is carried on the primary management connection. Refer to 6.3.2.3.9.21.

— **PKMv2 Group-Key-Update-Command.** A BS transmits a PKMv2 Group-Key-Update-Command message to initiate and push newly updated GKEK and GTEK to every SSs served with the specific multicast or broadcast service.

### 7.9.3 Encryption of GKEK

The BS encrypts the value fields of the GKEK in the Key Update Command message for the GKEK update mode and sends the encrypted GKEK to each SS served with the specific multicast service or the broadcast service. This field is encrypted using several algorithms. See 7.5.4.5.2 for details.

### 7.9.4 Message authentication keys for the Key Update Command message

One of the HMAC-Digest attribute or the CMAC Digest attribute is used for Key Update Command message authentication.

Input key used to generate HMAC authentication keys of Key Update Command message is different according to the value field of the Key Push Modes. The AK shall be used for generation of HMAC-Digest included in the Key Update Command message for the GKEK update mode and the GKEK shall be used for generation of HMAC-Digest included in the Key Update Command message for the GTEK update mode. See 7.2.2.2.9 for details. The CMAC_KEY_GD and HMAC_KEY_GD should be recomputed when a new GKEK is used.
8. Physical layer (PHY)

8.1 WirelessMAN-SC PHY specification

8.1.1 Overview

This PHY specification, targeted for operation in the 10–66 GHz frequency band, is designed with a high degree of flexibility in order to allow service providers the ability to optimize system deployments with respect to cell planning, cost, radio capabilities, services, and capacity.

In order to allow for flexible spectrum usage, both TDD and FDD configurations (8.1.3) are supported. Both cases use a burst transmission format whose framing mechanism (8.1.4.1) supports adaptive burst profiling in which transmission parameters, including the modulation and coding schemes, may be adjusted individually to each SS on a frame-by-frame basis. The FDD case supports full-duplex SSs as well as half-duplex SSs, which do not transmit and receive simultaneously.

The UL PHY is based on a combination of TDMA and DAMA. In particular, the UL channel is divided into a number of time slots. The number of slots assigned for various uses (registration, contention, guard, or user traffic) is controlled by the MAC in the BS and may vary over time for optimal performance. The DL channel is TDM, with the information for each SS multiplexed onto a single stream of data and received by all SSs within the same sector. To support half-duplex FDD SSs, provision is also made for a TDMA portion of the DL.

The DL PHY includes a TCS that inserts a pointer byte at the beginning of the payload to help the receiver identify the beginning of a MAC PDU. Data bits coming from the TCS are randomized, FEC encoded, and mapped to a QPSK, 16 quadrature amplitude modulation (QAM), or 64-QAM (optional) signal constellation.

8.1.2 Framing

This PHY specification operates in a framed format (6.3.7). Within each frame are a DL subframe and an UL subframe. The DL subframe begins with information necessary for frame synchronization and control. In the TDD case, the DL subframe comes first, followed by the UL subframe. In the FDD case, UL transmissions occur concurrently with the DL frame.

Each SS shall attempt to receive all portions of the DL except for those bursts whose burst profile is either not implemented by the SS or is less robust than the SS’s current operational DL burst profile. Half-duplex SSs shall not attempt to listen to portions of the DL coincident with their allocated UL transmission, if any, adjusted by their Tx time advance.
8.1.2.1 Supported frame durations

Table 211 indicates the supported frame durations.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

8.1.3 Duplexing techniques and PHY Type parameter encodings

Both FDD and TDD are supported. The duplexing method shall be reflected in the PHY Type parameter (11.4.1) as shown in Table 212.

<table>
<thead>
<tr>

</tr>
<tr>
<td>FDD</td>
<td>1</td>
</tr>
</tbody>
</table>

8.1.3.1 FDD operation

In FDD operation, the UL and DL channels are on separate frequencies. The capability of the DL to be transmitted in bursts facilitates the use of different modulation types and allows the system to simultaneously support full-duplex SSs (which can transmit and receive simultaneously) and half-duplex SSs (which do not). Note that the DL carrier may be continuous, as demonstrated in Figure 177 (third frame). Figure 177 describes the basics of the FDD operation.
In the case of a half-duplex SS, transition gaps, as described in 8.1.3.2.1 and 8.1.3.2.2, apply.

8.1.3.2 TDD operation

In the case of TDD, the UL and DL transmissions share the same frequency but are separated in time, as shown in Figure 178. A TDD frame also has a fixed duration and contains one DL and one UL subframe. The TDD framing is adaptive in that the link capacity allocated to the DL versus the UL may vary.

\[ n = \left( \text{Symbol Rate} \times \text{Frame Duration} \right) / 4 \]

Figure 178—TDD frame structure

8.1.3.2.1 TTG

The TTG is a gap between the DL burst and the subsequent UL burst. This gap allows time for the BS to switch from Tx to Rx mode. During this gap, the BS is not transmitting modulated data but simply allowing the BS transmitter carrier to ramp down, the Tx/Rx antenna switch to actuate, and the BS receiver section to
activate. After the gap, the BS receiver shall look for the first symbols of UL burst. This gap is an integer number of PS durations and starts on a PS boundary.

**8.1.3.2.2 RTG**

The RTG is a gap between the UL burst and the subsequent DL burst. This gap allows time for the BS to switch from Rx to Tx mode. During this gap, the BS is not transmitting modulated data but simply allowing the BS transmitter carrier to ramp up and the Tx/Rx antenna switch to actuate. After the gap, the SS receivers shall look for the first symbols of QPSK modulated data in the DL burst. This gap is an integer number of PS durations and starts on a PS boundary.

**8.1.4 DL PHY**

The available bandwidth in the DL direction is defined with a granularity of one PS. The available bandwidth in the UL direction is defined with a granularity of one minislot, where the minislot length is $2^m$ PSs ($m$ ranges from 0 through 7). The number of PSs with each frame is a function of the symbol rate. The symbol rate is selected in order to obtain an integral number of PSs within each frame. For example, with a 20 MBd symbol rate, there are 5000 PSs within a 1 ms frame.

**8.1.4.1 DL subframe**

The structure of the DL subframe using TDD is illustrated in Figure 179. The DL subframe begins with a Frame Start Preamble used by the PHY for synchronization and equalization. This is followed by the frame control section, containing DL-MAP and UL-MAP stating the PSs at which bursts begin. The following TDM portion carries the data, organized into bursts with different burst profiles and therefore different level of transmission robustness. The bursts are transmitted in order of decreasing robustness. For example, with the use of a single FEC type with fixed parameters, data begins with QPSK modulation, followed by 16-QAM, followed by 64-QAM. In the case of TDD, a TTG separates the DL subframe from the UL subframe.

Each SS receives and decodes the control information of the DL and looks for MAC headers indicating data for that SS in the remainder of the DL subframe.

![Figure 179—TDD DL subframe structure](image)

---

Copyright © 2009 IEEE. All rights reserved.
In the FDD case, the structure of the DL subframe is illustrated in Figure 180. Like the TDD case, the DL subframe begins with a Frame Start Preamble followed by a frame control section and a TDM portion organized into bursts transmitted in decreasing order of burst profile robustness. This TDM portion of the DL subframe contains data transmitted to one or more of the following:

- Full-duplex SSs
- Half-duplex SSs scheduled to transmit later in the frame than they receive
- Half-duplex SSs not scheduled to transmit in this frame

The FDD DL subframe continues with a TDMA portion used to transmit data to any half-duplex SSs scheduled to transmit earlier in the frame than they receive. This allows an individual SS to decode a specific portion of the DL without the need to decode the entire DL subframe. In the TDMA portion, each burst begins with the DL TDMA Burst Preamble for phase resynchronization. Bursts in the TDMA portion need not be ordered by burst profile robustness. The FDD frame control section includes a map of both the TDM and TDMA bursts.

<table>

<td>TDM</td>
<td>2</td>
<td>QPSK</td>
</tr>
</tbody>
</table>
Both preambles use QPSK modulation and are based upon +45 degrees rotated constant amplitude zero autocorrelation (CAZAC) sequences (Milewski [B39]). The amplitude of the preamble shall depend on the DL power adjustment rule (8.1.4.4.7). In the case of the constant peak power scheme (power adjustment rule = 0), the preamble shall be transmitted so that its constellation points coincide with the outermost constellation points of the modulation(s) scheme in the burst. In the case of the constant mean power scheme (power adjustment rule = 1), it shall be transmitted with the mean power of the constellation points of the modulation scheme(s) in the burst.

The frame start preamble (Table 214) consists of a 32-symbol sequence generated by repeating a 16-symbol CAZAC sequence. The DL TDMA burst preamble (Table 215) consists of a 16-symbol sequence generated by repeating an 8-symbol CAZAC sequence.

#### 8.1.4.1.2 Frame control section

The frame control section is the first portion of the DL frame following the preamble. It is used for control information destined for all SSs. This control information shall not be encrypted. The information transmitted in this section always uses the well-known DL burst profile with DIUC = 0.

The frame control section shall contain a DL-MAP message (6.3.2.3.2) for the channel followed by one UL-MAP message (6.3.2.3.4) for each associated UL channel. In addition, it may contain DCD and UCD messages (6.3.2.3.1 and 6.3.2.3.3) following the last UL-MAP message. No other messages shall be sent in the frame control section.
8.1.4.1.2.1 DL-MAP elements

The IEs as defined in Table 216 follow the Number of DL-MAP Elements field of the DL-MAP message, as described in 6.3.2.3.2. The Map IEs shall be in chronological order. Note that this is not necessarily DIUC order (as DIUC numbering does not necessarily reflect robustness of the burst profile) or CID order.

### 8.1.4.1.2.2 DL-MAP PHY synchronization field definition

The format of the PHY Synchronization Field of the DL-MAP message, as described in 6.3.2.3.2, is given in Table 217.

**Network Configuration Type**

Defines the network configuration type. If the network is DM then an FCH expected field is included. This is a 16-bit field that defines when the next frame preamble and FCH shall be transmitted. As this transmission will be directed to a given SS, it is effectively a private transmission to that SS.
Frame Duration Code
Defined in Table 211.

Frame Number
Incremented by 1 each frame and eventually wraps around to zero.

FCH expected
The FCH expected shall indicate the transmission of a DL-MAP, UL-MAP, DCD or UCD. For network entry of DM it is possible to increase the frequency of occurrence of FCH transmission to assist new nodes to enter the network. The frequency can be reduced for the case of steady state network operation.

8.1.4.1.2.3 UL-MAP allocation start time definition
The allocation start time is the effective start time of the UL allocation defined by the UL-MAP in units of minislots. The start time is relative to the start of the frame in which the UL-MAP message is transmitted.

8.1.4.1.2.4 Required DCD parameters
The following parameters shall be included in the DCD message:

— BS Tx Power
  NOTE—To be used by SSs to validate radio link conditions.
— PHY type
— FDD/TDD frame duration

8.1.4.1.2.5 Downlink_Burst_Profile
Each Downlink_Burst_Profile in the DCD message (6.3.2.3.1) shall include the following parameters:

— Modulation type
— FEC Code Type
— Last codeword length
— Preamble Presence

If the FEC Code Type is 1, 2, or 3 (RS codes), the Downlink_Burst_Profile shall also include the following:

— RS information bytes ($K$)
— RS parity bytes ($R$)

If the FEC Code Type is 2, the Downlink_Burst_Profile shall also include the following:

— BCC code type

If the FEC Code Type is 4, the Downlink_Burst_Profile shall also include the following:

— Block Turbo Code (BTC) row code type
— BTC column code type
— BTC interleaving type

The mapping between Burst Profile and DIUC is given in Table 218.

</tr>
</tbody>
</table>

The Downlink Burst Profile 1 (DIUC = 0) parameters defined in 8.1.4.4.5 shall be stored in the SS and shall not be included in the DCD message.
The Gap Downlink Burst Profile (DIUC = 14) indicates a silent interval in DL transmission. It is well-known and shall not be defined in the DCD message.

The End of DL-MAP Burst Profile (DIUC = 15) indicates the first PS after the end of the DL subframe. It is well known and shall not be included in the DCD message.

Table 219 defines the format of the Downlink_Burst_Profile, which is used in the DCD message (6.3.2.3.1). The Downlink_Burst_Profile is encoded with a Type of 1, an 8-bit length, and a 4-bit DIUC. The DIUC field is associated with the DL burst profile and thresholds. The DIUC value is used in the DL-MAP message to specify the Burst Profile to be used for a specific DL burst.

#### 8.1.4.2 DL burst allocation

The DL data sections are used for transmitting data and control messages to the specific SSs. The data are always FEC coded and are transmitted at the current operating modulation of the individual SS. In the TDM portion, data shall be transmitted in order of decreasing burst profile robustness. In the case of a TDMA portion, the data are grouped into separately delineated bursts that need not be in robustness order (see 8.1.4.1). The DL-MAP message contains a map stating at which PS the burst profile changes occur. In the case of TDMA, if the DL data does not fill the entire DL subframe, the transmitter is shut down. FEC codewords within a burst are arranged in a compact form aligned to bit-level boundaries. This implies that, while the first FEC codeword shall start on the first PS boundary, succeeding FEC codewords may start even within a modulation symbol or within a PS if the succeeding FEC codeword ended within a modulation symbol or within a PS. The exact alignment conditions depend on the burst profile parameters.

In the case of shortening the last FEC block within a burst (optional, see 11.4.2), the DL-MAP provides an implicit indication.

In general, the number of PSs $i$ (which shall be an integer) allocated to a particular burst can be calculated from the DL-MAP, which indicates the starting position of each burst as well as the burst profiles. Let $n$ denote the minimum number of PSs required for one FEC codeword of the given burst profile (note that $n$ is not necessarily an integer). Then, $i = kn + j + q$, where $k$ is the number of whole FEC codewords that fit in the burst, $j$ (not necessarily an integer) is the number of PSs occupied by the largest possible shortened codeword, and $q (0 \leq q < 1)$ is the number of PSs occupied by pad bits inserted at the end of the burst to guarantee that $i$ is an integer. In Fixed Codeword Operation (8.1.4.4.1), $j$ is always 0. Recall that a codeword can end partway through a modulation symbol as well as partway through a PS. When this occurs, the next codeword shall start immediately, with no pad bits inserted. At the end of the burst (i.e., when there is no next codeword), then $4q$ symbols are added as padding (if required) to complete the PS allocated in the
DL-MAP. The number of padding bits in these padding symbols is \(4q\) times the modulation density, where the modulation density is 2 for QPSK, 4 for 16-QAM, and 6 for 64-QAM. Note that padding bits may be required with or without shortening. Either \(k\) or \(j\), but not both, may be zero. The number \(j\) implies some number of bits \(b\). Assuming \(j\) is nonzero, it shall be large enough so that \(b\) is larger than the number of FEC bits, \(r\), added by the FEC scheme for the burst. The number of bits (preferably an integral number of bytes) available for user data in the shortened FEC codeword is \(b-r\). Any bits that may be left over from a fractional byte are encoded as binary 1 to ensure compatibility with the choice of 0xFF for pad. A codeword cannot have less than six information bytes. This is illustrated in Figure 181.

![Diagram of DL-MAP usage with shortened FEC blocks—TDM case](image)

**Figure 181**—DL-MAP usage with shortened FEC blocks—TDM case

In the case of TDMA DL, a burst includes the DL TDMA burst preamble of length \(p\) PSs, and the DL-MAP entry points to its beginning (Figure 182).

### 8.1.4.3 DL TCS

The DL payload shall be segmented into blocks of data designed to fit into the proper codeword size after the CS pointer byte is added. Note that the payload length may vary, depending on whether shortening of codewords is allowed for this burst profile. A pointer byte shall be added to each payload segment, as illustrated in Figure 183.

The pointer field identifies the byte number in the packet, which indicates either the beginning of the first MAC PDU to start in the packet or the beginning of any stuff bytes that precede the next MAC PDU. For reference, the first byte in the packet is referred to as byte number 1. If no MAC PDU or stuff bytes begin in the CS packet, then the pointer byte is set to 0. When no data is available to transmit, a stuff_byte pattern having a value (0xFF) shall be used within the payload to fill any gaps between the IEEE 802.16 MAC PDUs. This value is chosen as an unused value for the first byte of the IEEE 802.16 MAC PDU, which is designed to never have this value.
8.1.4.4 DL PMD sublayer

The DL PHY coding and modulation for this mode is summarized in the block diagram in Figure 184.
8.1.4.4.1 Burst profile definitions

The DL channel supports adaptive burst profiling on the user data portion of the frame. Up to twelve burst profiles can be defined. The parameters of each are communicated to the SSs via MAC messages during the frame control section of the DL frame (see 8.1.4.1). The DL channel and burst profiles are communicated to the SSs via the MAC messages described in 6.3.2.3.1.

The use of DIUCs shall be constrained as shown in Table 220.

8.1.4.4.2 DL PHY SS capability set parameters

Since there are optional modulation and FEC schemes that can be implemented at the SS, a method for identifying the capability to the BS is required (i.e., including the highest order modulation supported, the optional FEC coding schemes supported, and the minimum shortened last codeword length supported). This information shall be communicated to the BS during the subscriber registration period.
8.1.4.4.3 Randomization

Randomization shall be employed to minimize the possibility of transmission of an unmodulated carrier and to ensure adequate numbers of bit transitions to support clock recovery. The stream of DL packets shall be randomized by modulo-2 addition of the data with the output of the pseudo-random binary sequence (PRBS) generator, as illustrated in Figure 185. The generator polynomial for the PRBS shall be $c(x) = x^{15} + x^{14} + 1$.

![Randomizer logic diagram](image)

Figure 185—Randomizer logic diagram

At the beginning of each burst, the PRBS register is cleared and the seed value of 100101010000000 is loaded. A burst corresponds to either a TDM burst beginning with the frame start preamble or a TDMA burst beginning with a DL TDMA burst preamble (8.1.4.1.1). The seed value shall be used to calculate the randomization bits, which are combined in an XOR operation with the serialized bit stream of each burst. The randomizer sequence is applied only to information bits.

8.1.4.4.4 DL FEC

The FEC schemes are selectable from the types in Table 221.

</tbody>
</table>

Table 221—FEC Code Types

Implementation and use of Code Types 3 and 4 is optional. Code Types 1 and 2 shall be implemented by all BSs and SSs. Code Type 2 shall not be used except in the case of QPSK modulation. In the case of QPSK, any of the four Code Types may be used, with one exception: Code Type 2 shall always be used for the control channel (DIUC = 0).
The following is a summary of the four Code Types:

a) **Code Type 1: Reed-Solomon only**: This case is useful either for a large data block or when high coding rate is required. The protection could vary between $t = 0$ to $t = 16$.

b) **Code Type 2: Reed-Solomon + Block convolutional code (soft decodable)**: This case is useful for low to moderate coding rates providing good carrier-to-noise ratio (C/N) enhancements. The coding rate of the inner block convolutional code (BCC) is 2/3. Note: The number of information bytes shall be even in this case.

c) **Code Type 3: Reed-Solomon + Parity check**: This optional code is useful for moderate to high coding rates with small to medium size blocks (i.e., $K = 16, 53, \text{ or } 128$). The code itself is a simple bit wise parity check operating on byte (8 bit) level. The parity code can be used for error correction, preferably employing a soft decoder.

d) **Code Type 4: BTC**: This optional code is used to significantly lower the required carrier-to-interference ratio (C/I) level needed for reliable communication, and can be used to either extend the range of a BS or increase the code rate for greater throughput.

### 8.1.4.4.4.1 Outer code for Code Types 1–3, DL

The outer block code for Code Types 1–3 shall be a shortened, systematic Reed-Solomon code generated from GF(256) with information block length $K$ variable from 6–255 bytes and error correction capability $T$ able to correct from 0 to 16 byte errors. The specified code generator polynomials are given by the following:

**Code Generator Polynomial:**

$$g(x) = (x + \mu^0)(x + \mu^1)(x + \mu^2) ... (x + \mu^{2^7-1}), \text{ where } \mu = 02_{\text{hex}}$$

**Field Generator Polynomial:**

$$p(x) = x^8 + x^4 + x^3 + x^2 + 1$$

The specified code has a block length of 255 bytes and shall be configured as an RS(255,255-$R$) code with information bytes preceded by (255-$N$) zero symbols, where $N$ is the codeword length and $R$ the number of redundancy bytes ($R = 2 \times T$ ranges from 0 to 32, inclusive).

The value of $K$ and $T$ are specified for each burst profile by the MAC. Both Fixed Codeword Operation and Shortened Last Codeword Operation, as defined below, are allowed.

When using Code Type 2, the number of information bytes $K$ shall always be an even number so that the total codeword size ($K+R$) is also an even number. This is due to the fact that the BCC code requires a pair of bytes on which to operate.

a) **Fixed Codeword Operation.** In Fixed Codeword Operation, the number of information bytes $K$ is the same in each Reed-Solomon codeword. If the MAC messages in a burst require fewer bytes than are carried by an integral number of codewords, stuff bytes (FF$_{\text{hex}}$) shall be added between MAC messages or after the last MAC message so that the total message length is an integral multiple of $K$ bytes.

The SS determines the number of codewords in its DL burst from the DL-MAP message, which defines the beginning point of each burst, and hence the length. The BS determines the number of codewords in the DL as it scheduled this transmission event and is aware about its length. Using the burst length, both the SS and the BS calculate the number of full-length RS codewords that can be carried by each burst.

The process used by the BS to encode each burst is described below:

When the number of randomized MAC message bytes ($M$) entering the FEC process is less than $K$ bytes, Operation A shall be performed:
A1) Add \((K-M)\) stuff bytes (FF$_{\text{hex}}$) to the \(M\) byte block as a suffix.
A2) RS encode the \(K\) bytes and append the \(R\) parity bytes.
A3) Serialize the bytes and transmit them to the inner coder or the modulator MSB first.

When the number of randomized MAC message bytes \((M)\) entering the FEC process is greater than or equal to \(K\) bytes, Operation B shall be performed:

B1) RS encode the first \(K\) bytes and append the \(R\) parity bytes.
B2) Subtract \(K\) from \(M\) (Let \(M = M - K\)).
B3) If the new \(M\) is greater than or equal to \(K\), then repeat with the next set of bytes (go to B1).
B4) If the new \(M\) is zero, then stop; otherwise go to step A1 above and process the \(M < K\) case.

b) **Shortened Last Codeword Operation.** In the Shortened Last Codeword Operation, the number of information bytes in the final Reed-Solomon block of each burst is reduced from the normal number \(K\), while the number of parity bytes \(R\) remains the same. The BS tailors the number of information bytes in the last codeword in order to minimize the number of stuff bytes to add to the end of the MAC message. The length of the burst is then set to the minimum number of PSs required to transport all of the burst’s bytes, which include preamble, information, and parity bytes. The BS implicitly communicates the number of bytes in the shortened last codeword to the SS via the DL-MAP message, which defines the starting PS of each burst. The SS uses the DL-MAP information to calculate the number of full-length RS codewords and the length of the shortened last codeword that can be carried within the specified burst size. The BS performs a similar calculation as the SS for its encoding purposes.

To allow the receiving hardware to decode the previous Reed-Solomon codeword, no Reed-Solomon codeword shall have less than 6 information bytes. The number of information bytes carried by the shortened last codeword shall be between 6 and \(K\) bytes, inclusive. If the number of information bytes needing to be sent by the BS is less than 6 bytes of data, stuff bytes (FF$_{\text{hex}}$) shall be appended to the end of the data to bring the total number of information bytes up to the minimum of 6.

When using Code Type 2, the number of information bytes in the shortened last codeword shall always be an even number so that the total codeword size is also an even number. If an odd number of information bytes needs to be sent, a stuff byte (FF$_{\text{hex}}$) shall be appended to the end of the message to obtain an even number of bytes.

The process used by the BS to encode each burst is described below:

First, the full-sized Reed-Solomon codewords that precede the burst’s final codeword are encoded as in the fixed codeword mode above. The number of bytes allocated for the shortened last codeword by the UL-MAP is \(k\) bytes, which shall be between 6 and \(K\) bytes. The remaining \(M\) bytes of the message are then encoded into these \(k\) bytes using the following procedure:

A1) Add \((K-k)\) zero bytes to the \(M\) byte block as a prefix.
A2) RS encode the \(K\) bytes and append the \(R\) parity bytes.
A3) Discard all of the \((K-k)\) zero RS symbols.
A4) Serialize the bytes and transmit them to the inner coder or the modulator MSB first.
A5) Perform the inner coding operation (if applicable).

### 8.1.4.4.4.2 Inner code for Code Type 2, DL

The inner code in Code Type 2 consists of short block codes derived from a 4-state, nonsystematic, punctured convolutional code \((7,5)\). The trellis shall use the tail-biting method, where the last 2 bits of the message block are used to initialize the encoder memory, in order to avoid the overhead required for trellis termination. Thus, the encoder has the same initial and ending state for a message block.
For this concatenated coding scheme, the inner code message block is selected to be 16 bits. The puncturing pattern is described in Table 222 for the (24,16) case.

Table 222—Parameters of the inner codes for the BCC

| Inner code rate | Puncture pattern  
|-----------------|-----------------|
| 2/3             | G1 = 7, G2 = 5  
|                 | 11, 10          |

Figure 186 describes the exact encoding parity equations.

The number of information bytes shall be even since the BCC code operates on byte pairs.

8.1.4.4.4.3 Inner code for Code Type 3, DL

For Code Type 3, a parity check bit is added to each Reed-Solomon (RS) symbol individually and inserted as the LSB of the resulting 9-bit word. The parity is an XOR operation on all 8 bits within the symbol.

8.1.4.4.4 Code Type 4, DL

Code Type 4, the BTC, is a turbo-decoded product code (TPC). The idea of this coding scheme is to use extended Hamming block codes in a two-dimensional matrix. The two-dimensional code block is depicted in Figure 187. The \( k_x \) information bits in the rows are encoded into \( n_x \) bits, by using an extended Hamming binary block \((n_x, k_x)\) code. Likewise, \( k_y \) information bits in the columns are encoded into \( n_y \) bits, by using the same or possibly different extended Hamming binary block \((n_y, k_y)\) code. The resultant code block is composed of multiple rows and columns of the constituent extended Hamming block codes.
For this standard, the rows shall be encoded first. After encoding the rows, the columns are encoded using another block code \((n_y, k_y)\), where the check bits of the first code are also encoded. The overall block size of such a product code is \(n = n_x \times n_y\); the total number of information bits \(k = k_x \times k_y\); and the code rate is \(R = R_x \times R_y\), where \(R_i = k_i/n_i\) and \(i = x\) or \(y\).

The composite extended Hamming code specified requires addition of an overall even parity check bit at the end of each codeword.

The encoder for a BTC is composed of linear feedback shift registers (LFSRs), storage elements, and control logic. An example row (or column) encoder is shown here for clarification. The order of transmission is important so that the decoder may match for proper decoding. This specification mandates that the resultant code block be transmitted row by row, left to right, top to bottom, for the case when no interleaving is used (Interleaver Type 1 described below).

Table 223 provides the generator polynomials of the constituent Hamming codes used in this specification.

Table 223—SC Hamming code generator polynomials

<table>
<thead>
<tr>
<th>(n)</th>
<th>(k)</th>
<th>Generator polynomial</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>26</td>
<td>(x^5 + x^2 + 1)</td>
</tr>
<tr>
<td>63</td>
<td>57</td>
<td>(x^6 + x + 1)</td>
</tr>
</tbody>
</table>

The example circuit begins with all toggle switches in position A. Data to be encoded is fed as input 1 bit per clock (LSB first) to both the Hamming error correction code (ECC) computation logic and the overall even parity computation logic. Extended Hamming codes are systematic codes, so this data is also fed through as output on the encoded bit output. After all \(k\) bits are input, the toggle switches are moved to position B. At this point, data from the Hamming ECC logic is shifted out on the encoded bits bus. Finally, the overall parity bit is shifted out when the output select switch is moved to position C.
In order to encode the product code, each data bit is fed as input both into a row LFSR and a column LFSR. Note that only one row LFSR is necessary for the entire block, since data is written as input in row order. However, each column of the array shall be encoded with a separate LFSR. Each column LFSR is clocked for only one bit of the row, so a more efficient method of column encoding is to store the column LFSR states in a $k_x \times (n_y - k_y)$ storage memory. A single LFSR can then be used for all columns of the array. With each bit input, the appropriate column LFSR state is read from the memory, clocked, and written back to the memory.

The encoding process is demonstrated here with an example. Assume a two-dimensional $(8,4) \times (8,4)$ extended Hamming product code is to be encoded. This block has 16 data bits, and 64 total encoded bits. Table 224 shows the original 16 data bits denoted by $D_{xy}$, where $y$ corresponds to a column and $x$ corresponds to a row.

<table>
<thead>
<tr>
<th>$D_{11}$</th>
<th>$D_{21}$</th>
<th>$D_{31}$</th>
<th>$D_{41}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$D_{12}$</td>
<td>$D_{22}$</td>
<td>$D_{32}$</td>
<td>$D_{42}$</td>
</tr>
<tr>
<td>$D_{13}$</td>
<td>$D_{23}$</td>
<td>$D_{33}$</td>
<td>$D_{43}$</td>
</tr>
<tr>
<td>$D_{14}$</td>
<td>$D_{24}$</td>
<td>$D_{34}$</td>
<td>$D_{44}$</td>
</tr>
</tbody>
</table>

The first four bits of the array are fed into the row encoder input in the order $D_{11}, D_{21}, D_{31}, D_{41}$. Each bit is also fed as input into a unique column encoder. Again, a single column encoder may be used, with the state of each column stored in a memory. After the fourth bit is fed into the input, the first row encoder ECC bits are shifted out.

This process continues for all four rows of data. At this point, 32 bits have been taken as output from the encoder, and the four column encoders are ready to shift out the column ECC bits. This data is shifted out at the end of the row. This continues from the remaining three rows of the array. Table 225 shows the final encoded block with the 48 generated ECC bits denoted by $E_{yx}$.
Transmission of the block over the channel occurs in a linear manner; all bits of the first row are transmitted left to right, followed by the second row, etc. This allows for the construction of a near zero-latency encoder, since the data bits can be sent immediately over the channel, with the ECC bits inserted as necessary. For the $(8,4) \times (8,4)$ example, the output order for the 64 encoded bits is $D_{11}, D_{21}, D_{31}, D_{41}, E_{51}, E_{61}, E_{71}, E_{81}, D_{12}, D_{22}, \ldots, E_{88}$.

For easier readability, the following notation is used:

- The codes defined for the rows (x-axis) are binary $(n_x,k_x)$ block codes.
- The codes defined for the columns (y-axis) are binary $(n_y,k_y)$ block codes.
- Data bits are noted $D_{yx}$ and parity bits are noted $E_{yx}$.

a) Shortened BTC: To match packet sizes, removing symbols from the array shortens a product code. In general, rows or columns are removed until the appropriate size is reached. Codes selected shall have an integral number of information bytes. Different shortening approaches are applicable for BTC. In one method, rows and columns are deleted completely from an initial BTC array. For example, a 253 byte code is generated by starting with $(64,57)$ constituent codes and deleting thirteen rows and eleven columns. Another method uses a more systematic two-dimensional shortening. For example, a 128 byte BTC code is composed of $(64,57)$ constituent codes which are shortened by 25 rows and 25 columns, as described in Figure 189. The end result is a $(39,32) \times (39,32)$ array, which is capable of encoding $32 \times 32 = 1024$ bits (128 bytes) of data. Table 226 summarizes these example codes. A method for determining codes for payload sizes different than these examples is given at the end of this subclause.

Modifications to the encoder to support shortening are minimal. Since shortened bits are always zero, and zeros input to the encoder LFSR result in a zero state, the shortened bits can simply be ignored for the purpose of encoding. The encoder simply needs to know how many bits per row to input to the row LFSR before shifting out the result. Similarly, it must know the number of columns to input to the column encoders.

Transmission of the resultant code block shall start with the first data bit in the first row, proceed left to right, and then continue row by row from top to bottom.

b) **Interleaving:** When using the Block Turbo Coding, two modes of bit interleaving shall be supported. The interleaver mechanism shall be implemented by writing information bits into the encoder memory and reading out the encoded bits as follows:

1) **Interleaver type 1:** No interleaver. In this mode, the encoded bits are read from the encoder row by row, in the order that they were written.

2) **Interleaver type 2:** Block interleaver. In this mode, the encoded bits are read from the encoder after the first $k_2$ rows (Figure 187) are written into the encoder memory. The bits are read column by column, proceeding from the top position in the first column.

3) **Interleaver type 3: Reserved.** It is expected that other interleaving methods may yield better performance in some cases. So, this Interleaver type 3 has been reserved for future definition.

c) **Block mapping to the signal constellation:** The first encoded bit out shall be the LSB, which is the first bit written into the encoder.

d) **Method for determining codes for payload size different than the listed examples:** The following text describes a method for performing additional codeword shortening when the input block of data does not match exactly the codeword information size.

1) Take the required payload as specified in bytes and convert it to bits (i.e., multiply by 8).

2) Take the square root of the resultant number.

3) Round the result up to the next highest integer.

4) Select the smallest base constituent code from the available list that has a $k$ value equal to or greater than the value determined in step 3).

5) Subtract the value determined in step 3) from the $k$ value selected in step 4). This value represents the number of rows and columns that need to be shortened from the base constituent code selected in step 4).
This method will generally result in a code block whose payload is slightly larger than required in step 1 above. In order to address the residual bits, the column dimension \((n_y, k_y)\) should be shortened as needed and, as needed, zero bits may be stuffed into the last bits of the last row of the resulting code matrix. The zero bits in the last row should be discarded at the receiver.

*Example:* If a 20-byte payload code is desired, a \((32,26)\times(32,26)\) code is shortened by 13 rows and by 13 columns, resulting in a \((19,13)\times(19,13)\) code. There are 9 bits left over that are stuffed with zeros. Data input to the defined encoder is 160 data bits followed by 9 zero bits. The code block is transmitted starting with the bit in row 1 column 1 (the LSB), then left to right, and then row by row.

### 8.1.4.4.5 Definition of parameters for burst profile (DIUC = 0)

The burst profile with DIUC = 0 shall be configured with the parameters in Table 227.

### 8.1.4.4.6 Coding of the control portion of the frame

The frame control section of the DL frame (as defined in 8.1.4.1) shall be encoded with a fixed set of parameters known to the SS at initialization in order to ensure that all SSs can read the information. The modulation shall be QPSK, and the data shall be encoded with an outer \((46,26)\) Reed-Solomon code and an inner \((24,16)\) convolutional code. There shall be a minimum of two codewords per control portion of the frame when a DL allocation map is present. When a UL-MAP is present, it shall be concatenated with the DL allocation map to increase efficiency. This operation mode shall be designated as TDM Burst Profile 1 (DIUC = 0). Stuff bytes \((FFFF_{hex})\) shall be appended as necessary to the end of the control messages to fill up the minimum number of codewords.

### 8.1.4.4.7 DL modulation

To maximize utilization of the airlink, the PHY uses a multilevel modulation scheme. The modulation constellation can be selected per subscriber based on the quality of the RF channel. If link conditions permit, then a more complex modulation scheme can be utilized to maximize airlink throughput while still allowing reliable data transfer. If the airlink degrades over time, possibly due to environmental factors, the system can revert to the less complex constellations to allow more reliable data transfer.

In the DL, the BS shall support QPSK and 16-QAM modulation and, optionally, 64-QAM.

The sequence of modulation bits shall be mapped onto a sequence of modulation symbols \(S(k)\), where \(k\) is the corresponding symbol number. The number of bits per symbol depends on the modulation type. For QPSK, \(n = 2\); for 16-QAM, \(n = 4\); and for 64-QAM, \(n = 6\). \(B(m)\) denotes the modulation bit of a sequence to
be transmitted, where \( m \) is the bit number (\( m \) ranges from 1 through \( n \)). In particular, \( B(1) \) corresponds to the first bit entering the modulator, \( B(2) \) corresponds to the second bit entering the modulation, and so on.

In changing from one burst profile to another, the BS shall use one of two power adjustment rules: maintaining constant constellation peak power (power adjustment rule = 0), or maintaining constant constellation mean power (power adjustment rule = 1). In the constant peak power scheme, corner points are transmitted at equal power levels regardless of modulation type. In the constant mean power scheme, the signal is transmitted at equal mean power levels regardless of modulation type. The power adjustment rule is configurable through the DCD Channel Encoding parameters (11.4.1).

At the end of each burst, the final FEC-encoded message might not end exactly on a PS boundary. If this is the case, the end of the encoded message to the start of the next burst shall be filled with zero bits.

The complex modulation symbol \( S(k) \) shall take the value \( I + jQ \). The following subclauses apply to the base-band part of the transmitter.

8.1.4.4.8 Baseband pulse shaping

Prior to modulation, the $I$ and $Q$ signals shall be filtered by square-root raised cosine filters. The excess bandwidth factor $\alpha$ shall be 0.25. The ideal square-root raised cosine filter is defined by the following transfer function $H$, as shown in Equation (4):

$$H(f) = \begin{cases} 
1 & \text{for } |f| < f_s(1 - \alpha) \\
\frac{1}{2} \sin \left( \frac{\pi (f - f_s)}{f_s(1 + \alpha)} \right) & \text{for } f_s(1 - \alpha) \leq |f| \leq f_s(1 + \alpha) \\
0 & \text{for } |f| > f_s(1 + \alpha)
\end{cases}$$

(4)

where

$$f_s = \frac{1}{2T_s} = \frac{R_s}{2}$$

is the Nyquist frequency.

8.1.4.4.9 Transmitted waveform

The transmitted waveform at the antenna port $S(t)$ shall be as described by Equation (5).

$$S(t) = I(t)\cos(2\pi f_s t) - Q(t)\sin(2\pi f_s t)$$

(5)
where

\[ I(t) \text{ and } Q(t) \text{ are the filtered baseband (pulse-shaped) signals of the } I_k \text{ and } Q_k \text{ symbols} \]

\[ k \text{ is the discrete symbol index} \]

\[ f_c \text{ is the carrier frequency} \]

8.1.5 UL PHY

8.1.5.1 UL subframe

The structure of the UL subframe used by the SS to transmit to the BS is shown in Figure 193. The following three classes of bursts may be transmitted by the SS during the UL subframe:

a) Those that are transmitted in contention opportunities reserved for initial ranging.
b) Those that are transmitted in contention opportunities defined by Request Intervals reserved for response to multicast and broadcast polls.
c) Those that are transmitted in intervals defined by Data Grant IEs specifically allocated to individual SSs.

Any of these burst classes may be present in any given frame. They may occur in any order and any quantity (limited by the number of available PSs) within the frame, at the discretion of the BS UL scheduler as indicated by the UL_MAP in the frame control section (part of the DL subframe).

The bandwidth allocated for initial ranging and request contention opportunities may be grouped together and is always used with the UL burst profiles specified for initial ranging intervals (UIUC = 2) and request intervals (UIUC = 1), respectively. The remaining transmission slots are grouped by the SS. During its scheduled bandwidth, an SS transmits with the burst profile specified by the BS.

SSTGs separate the transmissions of the various SSs during the UL subframe. The gap allows for ramping down of the previous burst, followed by a preamble allowing the BS to synchronize to the new SS. The preamble and gap lengths are broadcast periodically in the UCD message.
8.1.5.1.1 UL burst preamble

Each UL burst shall begin with an UL preamble. This preamble is based upon a repetition of a ±45 degrees rotated constant amplitude zero auto-correlation (CAZAC) sequence (Milewski [B39]). The preamble length is either 16 symbols or 32 symbols. In the 16-symbol preamble (whose sequence is specified in Table 231), the CAZAC sequence is of length 8 and repeated once. In the 32-symbol preamble (whose sequence is specified in Table 232), the CAZAC sequence is of length 16 and repeated once.

</table>
The amplitude of the preamble shall depend on the UL power adjustment rule (8.1.5.3.7). In the case of the constant peak power scheme (power adjustment rule = 0), the preamble shall be transmitted so that its constellation points coincide with the outermost constellation points of the modulation scheme in use. In the case of the constant mean power scheme (power adjustment rule = 1), it shall be transmitted with the mean power of the constellation points of the modulation scheme in use.

The BS defines the preamble length through the UCD message.

### 8.1.5.1.2 UL-MAP IE definition

The format of UL-MAP IEs shall be as defined in Table 233 and utilized according to 6.3.2.3.4. The UIUC shall be one of the values defined in Table 234. The Offset indicates the start time, in units of minislots, of the burst relative to the Allocation Start Time given in the UL-MAP message. The end of the last allocated burst is indicated by allocating an End of map burst (CID = 0 and UIUC = 10) with zero duration. The time instants indicated by the offsets are the transmission times of the first symbol of the burst, including the preamble.

### 8.1.5.1.2.1 UL-MAP Extended IE format

A UL-MAP IE entry with a UIUC = 15 indicates that the IE carries special information and conforms to the structure shown in Table 235. A station shall ignore an extended IE entry with a subcode value for which the station has no knowledge. In the case of a known subcode value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

#### 8.1.5.1.2.2 UL-MAP Power Control IE format

When a power change for the SS is needed, the extended UIUC = 15 is used with the subcode set to 0x00 as shown in Table 236. The power control value is an 8-bit signed integer expressing the change in power level (in 0.25 dB units) that the SS should apply to correct its current transmission power. The CID used in the IE shall be the Basic CID of the SS.
8.1.5.1.3 Required UCD parameters

The following parameters shall be included in the UCD message:

— Preamble Length

The following parameters may be included in the UCD message and if absent shall have their default values:

— SSTG
— Roll-off Factor

UL symbol rate and frequency are implied by the DL symbol rate and frequency.

8.1.5.1.4 UL channel

Since SSs do not transmit in the UL channel until they have received some minimal configuration information from the BS, it is possible to support several different configurations that can be adjusted on an UL channel basis or on a burst by burst basis. These parameters, and their ranges, are supported through MAC signaling, as described in 6.3.2.3.3.

8.1.5.1.5 Uplink_Burst_Profile

Each Uplink_Burst_Profile in the UCD message (6.3.2.3.3) shall include the following parameters:

— Modulation type
— FEC Code Type
— Last codeword length
— Preamble Length
— Randomizer Seed

If the FEC Code Type is 1, 2, or 3 (RS codes), the Uplink_Burst_Profile shall also include the following:

— RS information bytes \((K)\)
— RS parity bytes \((R)\)
If the FEC Code Type is 2, the Uplink_Burst_Profile shall also include the following:

— BCC code type

If the FEC Code Type is 4, the Uplink_Burst_Profile shall also include the following:

— BTC row code type
— BTC column code type
— BTC interleaving type

Table 237 illustrates the format of the Uplink_Burst_Profile, which is encoded with a Type of 1.

<table>

</tr>
<tr>
<td>UIUC</td>
<td>4</td>
<td>—</td>
</tr>
<tr>
<td>TLV encoded information</td>
<td>variable</td>
<td>TLV-specific</td>
</tr>
</tbody>
</table>

Within each Uplink_Burst_Profile is an unordered list of PHY attributes, encoded as TLV values (see 11.3.1).  

8.1.5.2 UL TCS

The UL TCS operation shall be identical to the DL TCS operation, as described in 8.1.4.3.

8.1.5.3 UL PMD sublayer

The UL PHY coding and modulation are summarized in the block diagram shown in Figure 194.

8.1.5.3.1 Randomization for spectrum shaping

The UL modulator shall implement a randomizer using the polynomial \( x^{15} + x^{14} + 1 \). At the beginning of each burst, the register is cleared and the Randomizer Seed value 100101010000000 is loaded. The Randomizer Seed value shall be used to calculate the randomizer bit, which is combined in an XOR with the first bit of data of each burst (which is the MSB of the first symbol following the last symbol of the preamble).
8.1.5.3.2 UL FEC

The UL FEC schemes are as described in 8.1.4.4.4, including Table 221.

8.1.5.3.2.1 Outer code for Code Types 1–3, UL

The outer codes for Code Types 1–3 are nearly identical to those of the DL (8.1.4.4.1), with the following exceptions:

a) Fixed Codeword Operation. In the fixed codeword operation, the number of information bytes in each codeword is always the same \(K\). If the MAC messages in a burst require fewer bytes than are carried by an integral number of Reed-Solomon codewords, stuff bytes \((\text{FF}_{\text{hex}})\) shall be added between MAC messages or after the last MAC message so that the total message length is an integral multiple of \(K\) bytes.

The SS determines the number of codewords in its UL burst from the UL-MAP message, which defines the beginning point of each burst, and hence the length. The BS determines the number of codewords in the received UL burst as it scheduled this transmission event and is aware about its length. Using the burst length, both the SS and the BS calculate the number of full-length RS codewords that can be carried by each burst.

The process used by the SS to encode each burst is identical to the process performed by the BS in DL fixed codeword operation (8.1.4.4.1).

b) Shortened Last Codeword Operation. In the shortened last codeword operation, the number of information bytes in the final Reed-Solomon block of each burst is reduced from the normal number \(K\), while the number of parity bytes \(R\) remains the same. The BS tailors the number of information bytes in the last codeword, allowing the SS to transport as many information bytes as possible in each UL burst. The BS implicitly communicates the number of bytes in the shortened last codeword to the SS via the UL-MAP message, which defines the starting minislot of each burst. The BS performs a similar calculation as the SS for its decoding purposes.

To allow the receiving hardware to decode the previous Reed-Solomon codeword, no Reed-Solomon codeword shall have less than 6 information bytes. The number of information bytes carried by

---

**Figure 194—Conceptual block diagram of the UL PHY**

---
the shortened last codeword shall be between 6 and \( K \) bytes inclusive. In this mode, the BS shall only allocate bursts that result in shortened last codewords of the proper length.

When using Code Type 2, the number of information bytes in the shortened last codeword shall always be an even number so that the total codeword size is also an even number. Both BS and SS shall take this into account when calculating the number of information bytes in the last codeword.

The process used by the SS to encode each burst is identical to the process used by the BS in DL shortened last codeword operation (8.1.4.4.4.1).

8.1.5.3.2.2 Inner code for Code Type 2, UL

See 8.1.4.4.4.2.

8.1.5.3.2.3 Inner code for Code Type 3, UL

See 8.1.4.4.4.3.

8.1.5.3.2.4 Code Type 4, UL

Code Type 4 in the UL is similar to the DL case (8.1.4.4.4.4). Some exceptions apply to the UL due to the smaller payload expected within a burst. For example, using a similar two-dimensional shortening process, a 57-byte code is composed of \((32,26)\) constituent codes which have been shortened by seven rows and two columns as described in Figure 195. The end result is a \((30,24)\times(25,19)\) array, which is capable of encoding \(24 \times 19 = 456\) bits (57 bytes). Table 238 summarizes this code example.

![Figure 195—Structure of shortened 2 D block](image)

<td>UL</td>
</tr>
<tr>
<td>Block size (payload bits)</td>
<td>456 (57 bytes)</td>
</tr>
</tbody>
</table>
8.1.5.3.3 Shortening of FEC blocks in UL

Shortening of FEC blocks in the UL is identical to the handling in the DL as described in 8.1.4.2 or 8.1.4.4.1.

8.1.5.3.4 Number of scheduled UL bursts per frame

Only one scheduled burst (UIUC 4–9) per SS shall be included in the UL-MAP for any given frame.

8.1.5.3.5 Coding of the Request IE Uplink_Burst_Profile

The UL burst profile associated with the Request IE (UIUC = 1) shall use Modulation Type = 1 (QPSK) and shall use FEC Code Type = 1 or 2. The other parameters of the Uplink_Burst_Profile encoding shall be chosen so that the resulting UL burst profile is no less robust than the most robust UL burst profile associated with any of the Data Grant Burst Type IEs.

8.1.5.3.6 Coding of the initial ranging Uplink_Burst_Profile

The burst profile for the initial ranging UIUC shall be the same as for the frame control section, as defined in 8.1.4.4.6.

8.1.5.3.7 UL modulation

The modulation used on the UL channel shall be variable and set by the BS. QPSK shall be supported, while 16-QAM and 64-QAM are optional, with the mappings of bits to symbols identical to those described in 8.1.4.4.7.

In changing from one burst profile to another, the SS shall use one of two power adjustment rules: maintaining constant constellation peak power (power adjustment rule = 0), or maintaining constant constellation mean power (power adjustment rule = 1). In the constant peak power scheme, corner points are transmitted at equal power levels regardless of modulation type. In the constant mean power scheme, the signal is transmitted at equal mean power levels regardless of modulation type. The power adjustment rule is configurable through the UCD Channel Encoding parameters (11.3.1).

In changing from one modulation scheme to another (i.e., during burst profile change), sufficient RF power amplifier margins should be maintained to prevent violation of emissions masks.

8.1.5.3.8 Baseband pulse shaping

Prior to modulation, the I and Q signals shall be filtered by square-root raised cosine filters as specified in 8.1.4.4.8.

8.1.5.3.9 Transmitted waveform

The transmitted waveform shall be as described in 8.1.4.4.9.

8.1.6 Baud rates and channel bandwidths

A large amount of spectrum is potentially available in the 10–66 GHz range for PMP systems. Although regulatory requirements vary between different regions, sufficient commonality exists for a default RF channel bandwidth to be specified for each major region. This is necessary in order to ensure that products built to this standard have interoperability over the air interface.
Systems shall use Nyquist square-root raised cosine pulse shaping with a roll-off factor of 0.25 and shall operate on the default RF channel arrangement shown in Table 239. Note that baud rates are chosen to provide an integer number of PSs per frame. The frame duration choice compromises between transport efficiency (with lower frame overhead) and latency.

**Table 239—Baud rates and channel sizes for a roll-off factor of 0.25**

<table>
<thead>
<tr>

<td>5600</td>
</tr>
</tbody>
</table>

Due to wide variations in local regulations, no frequency plan is specified in this standard. No single plan can accommodate all cases. For example, the 24.5–26.5 GHz band in Europe is regulated by CEPT requirements concerning specific duplex spacing and rasters. This does not match a similar spectrum allocation in North America.

**8.1.7 Radio subsystem control**

**8.1.7.1 Synchronization technique**

The DL demodulator typically provides an output reference clock that is derived from the DL symbol clock. This reference can then be used by the SS to provide timing for rate critical interfaces when the DL clock is locked to an accurate reference at the BS.

Accurate UL time slot synchronization is supported through a ranging calibration procedure defined by the MAC to ensure that UL transmissions by multiple users do not interfere with each other. Therefore, the PHY needs to support accurate timing estimates at the BS, and the flexibility to finely modify the timing at the SS according to the transmitter characteristics specified in 8.1.8.

**8.1.7.2 Frequency control**

In order to meet more stringent coexistence requirements in place today, the transmitted RF center frequency for both the BS and at each SS shall have an accuracy better than $\pm 10 \times 10^{-6}$. The value shall be guaranteed over the complete temperature range and time of operation, i.e., aging for FWA equipment. In order to meet this main requirement, the following additional requirements have been derived for both BS and SS. The carrier frequency accuracy for the BS shall be better than $\pm 8 \times 10^{-6}$. Therefore

- The carrier frequency accuracy for the BS shall be $\pm 8 \times 10^{-6}$.
- The SS shall be locked in frequency to the BS.
- The carrier frequency of the SS shall be within $\pm 1 \times 10^{-6}$ of that of the BS.

**8.1.7.3 Power control**

The power control algorithm shall be supported for the UL channel with both an initial calibration and periodic adjustment procedure without loss of data. The BS should be capable of providing accurate power measurements of the received burst signal. This value can then be compared against a reference level, and the resulting error can be fed back to the SS in a calibration message coming from the MAC. The power
control algorithm shall be designed to support power attenuation due to distance loss or power fluctuations at rates of at most 20 dB/second with depths of at least 40 dB. The exact algorithm implementation is vendor-specific. The total power control range consists of both a fixed portion and a portion that is automatically controlled by feedback. The power control algorithm shall take into account the interaction of the RF power amplifier with different burst profiles. For example, when changing from one burst profile to another, margins should be maintained to prevent saturation of the amplifier and to prevent violation of emissions masks.

In support of FPC for SC, the CRABS report [B8] describes results that demonstrate LMDS frequency bands experiencing significant fast fading both due to rain and foliage impairments. FPC will also allow the decoupling of accurate rain fade margin setting on links and improve resilience. The report presented in Sydor [B44], although reporting measurements for the 5 GHz band, indicates fades up to 180dB/s based on obstruction from trees.

8.1.8 Minimum performance

This subclause details the minimum performance requirements for proper operation of systems in the frequency range of 24–32 GHz. The values listed in this subclause apply over the operational environmental ranges of the system equipment.

The philosophy taken in this subclause is to guarantee SS interoperability. Hence, the BS is described only in terms of its transmitter (Table 240), while the SS is described in terms of both its transmitter (Table 241) and receiver (Table 242). It is expected that BS manufacturers will use SS transmitter performance coupled with typical deployment characteristics (cell size, channel loading, near-far users, etc.) to profile their receiver equipment emphasizing specific performance issues as they require.

</tr>
</tbody>
</table>

NOTE—The interfering source shall be a continuous signal of the same modulation type as the primary signal. The spectral mask of the interfering signal shall depend on local regulatory requirements.
8.1.8.1 Propagation conditions

LOS radio propagation conditions between the BS and the SSs are required to achieve high quality and availability service. Also, the SSs need highly directional antennas, which minimize the number of multipaths and interference from unexpected sources. The intersymbol interference may occur as a consequence of multipaths.

8.1.8.1.1 Propagation models

In this subclause, the propagation models referred to in this specification are defined. No further BER performance degradation should be expected with all propagation model types.

### Table 242—Minimum SS receiver performance

| Bit error rate (BER) performance threshold | For BER = 1 × 10⁻³:  
QPSK: −94 + 10log₁₀(R)  
16-QAM: −87 + 10log₁₀(R)  
64-QAM: −79 + 10log₁₀(R)  

For BER = 1 × 10⁻⁶:  
QPSK: −90 + 10log₁₀(R)  
16-QAM: −83 + 10log₁₀(R)  
64-QAM: −74 + 10log₁₀(R)  

NOTE—Measured uncoded in dBm, where R denotes carrier symbol rate in MBd.  
Propagation models of Type 0, 1, or 2 (Table 243) are used. |
| Maximum Transition time from Tx to Rx and from Rx to Tx | 2 μs (TDD)  
20 μs (FDD, half-duplex terminal) |
| 1st Adjacent Channel Interference | At BER 10⁻³, for 3 dB degradation:  
C/I = −9 (QPSK), −2 (16-QAM), and +5 (64-QAM)  

At BER 10⁻³, for 1 dB degradation:  
C/I = −5 (QPSK), +2 (16-QAM), and +9 (64-QAM)  

At BER 10⁻⁶, for 3 dB degradation:  
C/I = −5 (QPSK), +2 (16-QAM), and +9 (64-QAM)  

At BER 10⁻⁶, for 1 dB degradation:  
C/I = −1 (QPSK), +6 (16-QAM), and +13 (64-QAM)  

NOTE—Measured uncoded, in dB. |
| 2nd Adjacent Channel Interference | At BER 10⁻³, for 3 dB degradation:  
C/I = −34 (QPSK), −27 (16-QAM), and −20 (64-QAM)  

At BER 10⁻³, for 1 dB degradation:  
C/I = −30 (QPSK), −22 (16-QAM), and −16 (64-QAM)  

At BER 10⁻⁶, for 3 dB degradation:  
C/I = −30 (QPSK), −23 (16-QAM), and −16 (64-QAM)  

At BER 10⁻⁶, for 1 dB degradation:  
C/I = −26 (QPSK), −20 (16-QAM), and −12 (64-QAM)  

NOTE—Measured uncoded, in dB. |
The channel model is expressed as follows:

$$H(j\omega) = C_1 \exp(-j\omega T_1) + C_2 \exp(-j\omega T_2) + C_3 \exp(-j\omega T_3)$$  \hspace{1cm} (6)

Here $C_1, C_2$, and $C_3$ are the complex tap amplitudes and $T_1, T_2$, and $T_3$ are the tap delays. These parameters are provided in Table 243, where $R$ is the channel symbol rate in MBd and the resulting tap delay is in ns. For example, if $R = 20$ MBd, then the resulting Type 2 tap delays will be 0, 20, and 40 ns.

### Table 243—Propagation models

<table>
<thead>
<tr>
<th>Propagation model</th>
<th>Tap number $i$</th>

<td>400/$R$</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>-0.095</td>
<td>800/$R$</td>
</tr>
</tbody>
</table>

NOTE—Propagation path parameters are valid for $R$ from 15 to 25 MBd.

Type 0 represents a clear LOS scenario. Type 1 and Type 2 represent typical deployment scenarios with weak multipath components, Type 1 having better conditions.

### 8.1.8.1.2 Rain fades

For 10–66 GHz frequencies of operation, the predominant fade mechanism is that resulting from rain attenuation. Fade depths are geographically dependent by rain rate region and are also conditioned by both frequency of operation and link distance. For a given set of equipment transmission parameters and a specified link availability requirement, the rain rate criteria establish the maximum cell radius appropriate to system operation.

An internationally accepted method for computation of rain fade attenuation probability is that defined by ITU-R P.530-8 [B36]. As an example, typical 28 GHz equipment parameters result in a maximum cell radius of about 3.5 km in ITU rain region K. This criteria applies for a link BER = $10^{-6}$ at a link availability of 99.995%. Further details on this example system model may be found in IEEE Std 802.16.2.

Another important issue is the impact of uncorrelated rain fading between an interference transmission link and a victim transmission link. Under rain fading conditions, the differential rain fading loss between the two transmission paths may have a significant impact on both intrasystem and intersystem link availability. At operational frequencies around 28 GHz, the estimated rain cell diameter is approximately 2.4 km (ITU-R P.452 [B33]). The effect of rain decorrelation may be estimated based on cell sector size and the specified frequency reuse plan.

A significant mitigation technique for the control of both intrasystem and intersystem interference is the angular discrimination provided by system antennas. The antenna radiation pattern envelope (RPE) discrimination has significance for both clear sky and rain faded propagation conditions. The RPE requirements for aggressive intrasystem frequency reuse plans may exceed the RPE requirements for the
control of inter-system coexistence. Recommended antenna RPE characteristics are described in IEEE Std 802.16.2.

8.1.8.2 Transmitter characteristics

Unless stated otherwise, the transmitter requirements are referenced to the transmitter output port and apply with the transmitter tuned to any channel.

8.1.8.2.1 Output power

In the following subclause, power is defined as the time-averaged power when emitting a signal (excluding off-time between bursts), measured over the randomized bits of one transmitted burst.

The power at which SS or BSs shall operate is specified in the following subclause.

8.1.8.2.1.1 BS

A BS shall not produce an effective isotropic radiated power (EIRP) spectral density exceeding either +28.5 dBmi/MHz or local regulatory requirements.

8.1.8.2.1.2 SS

An SS shall not produce an EIRP spectral density exceeding either +39.5 dBmi/MHz or local regulatory requirements.

8.1.8.2.2 Emission mask and adjacent channel performance (NFD)

Tx parameters shall comply with existing ETSI standards having more stringent requirements, in particular

— Frequency band 40.5 GHz to 43.5 GHz: EN 301 997-1
— Frequency band 24.25 GHz to 29.5 GHz: EN 301 213-3

In the DL channel, the transmitted spectrum shall not exceed the spectrum mask defined by Table 244, which specifies more stringent requirements than System Type C spectrum mask defined in EN 301 213-3.

<table>

### 8.1.8.2.3 Modulation accuracy and error vector magnitude (EVM)

The EVM defines the average constellation error with respect to the farthest constellation point power, as illustrated in Figure 196 and defined by Equation (7).

\[
EVM = \sqrt{\frac{1}{N} \sum_{N} \left( \Delta P^2 + \Delta Q^2 \right)} / S_{\text{max}}^2
\]

(7)

where

- \( N \) is the number of symbols in the measurement period and \( S_{\text{max}} \) the maximum constellation amplitude.

The EVM shall be measured over the continuous portion of a burst occupying at least 1/4 of the total transmission frame at maximum power settings.

The required EVM can be estimated from the transmitter implementation margin if the error vector is considered noise, which is added to the channel noise.

The implementation margin means the excess power needed to keep the C/N constant when going from the ideal to the real transmitter. EVM cannot be measured at the antenna connector but should be measured by an “ideal” receiver with a certain carrier recovery loop bandwidth specified in percent of the symbol rate. In
Based on the values in Table 247 the EVM values shall be the following:

— EVM 12% and 6% for 4-QAM, 16-QAM respectively when measured by an “ideal” receiver without an equalizer with a carrier recovery loop bandwidth of 1% to 5%; and

— EVM 10%, 3%, and 1.5% for 4-QAM, 16-QAM, and 64-QAM respectively when measured by an “ideal” receiver with an equalizer with a carrier recovery loop bandwidth of 1% to 5%.

The above measured EVM shall include the Tx filter accuracy, D/A-converter, modulator imbalances, untracked phase noise, and power amplifier (PA) nonlinearity.

### 8.1.9 Channel quality measurements

#### 8.1.9.1 Introduction

RSSI and CINR signal quality measurements and associated statistics can aid in such processes as BS selection/assignment and burst adaptive profile selection. As channel behavior is time-variant, both mean and standard deviation are defined.
The process by which RSSI measurements are taken does not necessarily require receiver demodulation lock; for this reason, RSSI measurements offer reasonably reliable channel strength assessments even at low signal levels. On the other hand, although CINR measurements require receiver lock, they provide information on the actual operating condition of the receiver, including interference and noise levels, and signal strength.

### 8.1.9.2 RSSI mean and standard deviation

When collection of RSSI measurements is mandated by the BS, an SS shall obtain an RSSI measurement from the DL burst preambles. From a succession of RSSI measurements, the SS shall derive and update estimates of the mean and the standard deviation of the RSSI, and report them via REP-RSP messages.

Mean and standard deviation statistics shall be reported in units of decibels relative to 1 mW (dBm) and decibels, respectively. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from –40 dBm (encoded 0x53) to –123 dBm (encoded 0x00). Values outside this range shall be assigned the closest extreme value within the scale. The standard deviation shall be quantized in 0.5 dB increments (i.e., standard deviation < 0.5 dB encoded 0x00, 0.5 dB ≤ standard deviation < 1.0dB encoded 0x01).

The method used to estimate the RSSI of a single message is left to individual implementation, but the relative accuracy of a single signal strength measurement, taken from a single message, shall be ± 2 dB, with an absolute accuracy of ± 4 dB. This shall be the case over the entire range of input RSSIs. In addition, the range over which these single-message measurements are measured should extend 3 dB on each side beyond the –40 dBm to –123 dBm limits for the final averaged statistics that are reported.

The (linear) mean RSSI statistics (in milliwatts), derived from a multiplicity of single messages, shall be updated using Equation (8).

\[
\hat{\mu}_{RSSI}[k] = \begin{cases} 
R[0] & k = 0 \\
(1 - \alpha_{avg})\hat{\mu}_{RSSI}[k-1] + \alpha_{avg}R[k] & k > 0
\end{cases} \quad \text{mW}
\]  

(8)

where

- \(k\) is the time index for the message (with the initial message being indexed by \(k = 0\), the next message by \(k = 1\), etc.)
- \(R[k]\) is the RSSI in mW measured during message \(k\), and \(\alpha_{avg}\) is an averaging parameter specified by the BS. The mean estimate in dBm shall then be derived from Equation (9).

\[
\mu_{RSSI \ dBm}[k] = 10\log(\hat{\mu}_{RSSI}[k]) \quad \text{dBm}
\]  

(9)

To solve for the standard deviation in dB, the expectation-squared statistic shall be updated using Equation (10).

\[
\hat{\sigma}^2_{RSSI}[k] = \begin{cases} 
|R[0]|^2 & k = 0 \\
(1 - \alpha_{avg})\hat{\sigma}^2_{RSSI}[k-1] + \alpha_{avg}|R[k]|^2 & k > 0
\end{cases}
\]  

(10)

Apply the result to Equation (11).
When CINR measurements are mandated by the BS, an SS shall obtain a CINR measurement from the DL burst preambles. From a succession of these measurements, the SS shall derive and update estimates of the mean and the standard deviation of the CINR, and report them via REP-RSP messages.

Mean and standard deviation statistics for CINR shall be reported in units of dB. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from a minimum of –20 dB (encoded 0x00) to a maximum of 40 dB (encoded 0x3C). Values outside this range shall be assigned the closest extreme value within the scale.

The method used to estimate the CINR of a single message is left to individual implementation, but the relative and absolute accuracy of a CINR measurement derived from a single message shall be ±1 dB and ±2 dB, respectively, for all input CINRs above 0 dB. In addition, the range over which these single-packet measurements are measured should extend 3 dB on each side beyond the –20 dB to 40 dB limits for the final reported, averaged statistics.

One possible method to estimate the CINR of a single message is by normalizing the mean-squared residual error of detected data symbols (and/or pilot symbols) by the average signal power using Equation (12).

\[
CINR[k] = \frac{A[k]}{E[k]},
\]

where

\( CINR[k] \) is the (linear) CINR for message \( k \)

\( r[k,n] \) is received symbol \( n \) within message \( k \)

\( s[k,n] \) is the corresponding detected or pilot symbol corresponding to received symbol \( n \)

\[
A[k] = \sum_{n=0}^{N-1} |s[k,n]|^2
\]

is the average signal power, which is normally kept constant within a message by action of automatic gain control (AGC); and

\[
E[k] = \sum_{n=0}^{N-1} |r[k,n] - s[k,n]|^2
\]

The mean CINR statistic (in decibels) shall be derived from a multiplicity of single messages using Equation (15).

\[
\hat{\mu}_{CINR} dB = 10 \log(\hat{\mu}_{CINR[k]})
\]

where
where

\[ k \] is the time index for the message (with the initial message being indexed by \( k = 0 \), the next message by \( k = 1 \), etc.)

\( CINR[k] \) is a linear measurement of CINR (derived by any mechanism that delivers the prescribed accuracy) for message \( k \); and \( \alpha_{avg} \) is an averaging parameter specified by the BS.

To solve for the standard deviation, the expectation-squared statistic shall be updated using Equation (17).

\[
\hat{\sigma}^2_{CINR[k]} = \begin{cases} 
CINR[0]^2 & k = 0 \\
(1 - \alpha_{avg})\hat{\sigma}^2_{CINR[k-1]} + \alpha_{avg}CINR[k]^2 & k > 0 
\end{cases}
\]  

(17)

and the result applied to Equation (18).

\[
\hat{\sigma}_{CINR \ dB} = 5\log\left(\frac{\hat{\sigma}^2_{CINR[k]} - (\hat{\mu}_{CINR[k]})^2}{d\log_{10}}\right) \ dB
\]

(18)

8.2 Reserved

8.3 WirelessMAN-OFDM PHY

8.3.1 Introduction

The WirelessMAN-OFDM PHY is based on OFDM modulation and designed for NLOS operation in the frequency bands below 11 GHz as per 1.3.4.

8.3.1.1 OFDM symbol description

8.3.1.1.1 Time domain

Inverse-Fourier-transforming creates the OFDM waveform; this time duration is referred to as the useful symbol time \( T_b \). A copy of the last \( T_g \) of the useful symbol period, termed CP, is used to collect multipath, while maintaining the orthogonality of the tones. Figure 197 illustrates this structure.

The transmitter energy increases with the length of the guard time while the receiver energy remains the same (the cyclic extension is discarded), so there is a \( 10\log\left(1 - T_g/(T_b + T_g)\right)/\log(10) \) dB loss in \( E_b/N_0 \). The CP overhead fraction and resultant SNR loss could be reduced by increasing the FFT size, which would however, among other things, adversely affect the sensitivity of the system to phase noise of the oscillators. Using a cyclic extension, the samples required for performing the FFT at the receiver can be taken anywhere over the length of the extended symbol. This provides multipath immunity as well as a tolerance for symbol time synchronization errors.
On initialization, an SS should search all possible values of CP until it finds the CP being used by the BS. The SS shall use the same CP on the UL. Once a specific CP duration has been selected by the BS for operation on the DL, it should not be changed. Changing the CP would force all the SSs to resynchronize to the BS.

8.3.1.1.2 Frequency domain

The frequency domain description includes the basic structure of an OFDM symbol.

An OFDM symbol (see Figure 198) is made up from subcarriers, the number of which determines the FFT size used. There are three subcarrier types. They are as follows:

- Data subcarriers: For data transmission
- Pilot subcarriers: For various estimation purposes
- Null subcarriers: No transmission at all, for guard bands, nonactive subcarriers and the DC subcarrier.

NOTE—The example in Figure 198 shows the amplitude of the real (in-phase) component of an OFDM symbol with QPSK modulated data.

The purpose of the guard bands is to enable the signal to naturally decay and create the FFT “brick Wall” shaping. Subcarriers are nonactive only in the case of subchannelized transmission by an SS.

Subchannelized transmission in the UL is an option for an SS, and shall only be used if the BS signals its capability to decode such transmissions.
8.3.2 OFDM symbol parameters and transmitted signal

8.3.2.1 Primitive parameter definitions

The following four primitive parameters characterize the OFDM symbol:

- **BW**: This is the nominal channel bandwidth.
- **N\textsubscript{used}**: Number of used subcarriers.
- **n**: Sampling factor. This parameter, in conjunction with **BW** and **N\textsubscript{used}**, determines the subcarrier spacing, and the useful symbol time. Required values of this parameter are specified in 8.3.2.4.
- **G**: This is the ratio of CP time to “useful” time. Required values of this parameter are specified in 8.3.2.4.

8.3.2.2 Derived parameter definitions

The following parameters are defined in terms of the primitive parameters of 8.3.2.1:

- **N\textsubscript{FFT}**: Smallest power of two greater than **N\textsubscript{used}**
- **Sampling Frequency**: \( F_s = \text{floor}(n \cdot BW / 8000) \times 8000 \)
- **Subcarrier spacing**: \( \Delta f = F_s / N\textsubscript{FFT} \)
- **Useful symbol time**: \( T_b = 1 / \Delta f \)
- **CP Time**: \( T_g = G \cdot T_b \)
- **OFDM Symbol Time**: \( T_s = T_b + T_g \)
- **Sampling time**: \( T_s / N\textsubscript{FFT} \)

8.3.2.3 Transmitted signal

Equation (19) specifies the transmitted signal voltage to the antenna, as a function of time, during any OFDM symbol.

\[
s(t) = \Re \left\{ e^{j2\pi f_c t} \sum_{k = -N_{\text{used}}/2}^{N_{\text{used}}/2} c_k \cdot e^{j2\pi k\Delta f(t - T_g)} \right\}
\]

where

- **t** is the time elapsed since the beginning of the subject OFDM symbol, with \( 0 < t < T_s \)
- **c_k** is a complex number; the data to be transmitted on the subcarrier whose frequency offset index is **k**, during the subject OFDM symbol. It specifies a point in a QAM constellation. In subchannelized transmissions, **c_k** is zero for all unallocated subcarriers.

8.3.2.4 Parameters of transmitted signal

The parameters of the transmitted OFDM signal, transmitted as in 8.3.2.3, are given in Table 248.

8.3.3 Channel coding

Channel coding is composed of three steps: randomizer, FEC, and interleaving. They shall be applied in this order at transmission. The complementary operations shall be applied in reverse order at reception.
Table 248—OFDM symbol parameters

Subchannel Index:

Allocated Frequency offset indices of subcarriers:

Note that pilot subcarriers are allocated only if two or more subchannels are allocated.
8.3.3.1 Randomization

Data randomization is performed on each burst of data on the DL and UL. The randomization is performed on each allocation (DL or UL); in other words, for each allocation of a data block (subchannels on the frequency domain and OFDM symbols on the time domain), the randomizer shall be used independently. If the amount of data to transmit does not fit exactly the amount of data allocated, padding of 0xFF (“1” only) shall be added to the end of the transmission block for the unused integer bytes. For RS-CC- and CC-encoded data (see 8.3.3.2.1), padding will be added to the end of the transmission block, up to the amount of data allocated minus one byte, which shall be reserved for the introduction of a 0x00 tail byte by the FEC. For BTC (8.3.3.2.2) and CTC (8.3.3.2.3), if implemented, padding will be added to the end of the transmission block, up to the amount of data allocated.

The shift-register of the randomizer shall be initialized for each new allocation.

The PRBS generator shall be as shown in Figure 199. Each data byte to be transmitted shall enter sequentially into the randomizer, MSB first. Preambles are not randomized. The seed value shall be used to calculate the randomization bits, which are combined in an XOR operation with the serialized bit stream of each burst. The randomizer sequence is applied only to information bits.

The bits issued from the randomizer shall be applied to the encoder.

On the DL, the randomizer shall be reinitialized at the start of each frame, and at the start of the STC zone only when a FCH-STC is present, with the sequence: \(1\ 0\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\). The randomizer shall not be reset at the start of the burst immediately following FCH or FCH-STC. At the start of subsequent bursts, the randomizer shall be initialized with the vector shown in Figure 200. The frame number used for initialization refers to the frame in which the DL burst is transmitted.

For a DL subchannelization zone (see 8.3.5.1.1), the randomizer is initialized in an equivalent manner. At the start of the DL subchannelized zone, the randomizer shall be reinitialized to the sequence \(1\ 0\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\). The randomizer shall not be reset at the start of the first burst in the CCH. At the start of subsequent bursts, the randomizer shall be initialized with the vector shown in Figure 200. The frame number used for initialization refers to the frame in which the subchannelized burst is transmitted and can be obtained from the SBCH_DLFP (see Table 262 in 8.3.5.1.1).
On the UL, the randomizer is initialized with the vector shown in Figure 201. The frame number used for initialization is that of the frame in which the UL map that specifies the UL burst was transmitted.

**8.3.3.2 FEC**

An FEC, consisting of the concatenation of a Reed-Solomon outer code and a rate-compatible convolutional inner code, shall be supported on both UL and DL. Support of BTC and CTC is optional. The most robust burst profile shall always be used as the coding mode when requesting access to the network and in the FCH burst.

The encoding is performed by first passing the data in block format through the RS encoder and then passing it through a zero-terminating convolutional encoder.

**8.3.3.2.1 Concatenated Reed-Solomon-convolutional code (RS-CC)**

The Reed-Solomon encoding shall be derived from a systematic RS ($N = 255, K = 239, T = 8$) code using $GF(2^8)$,

where

- $N$ is the number of overall bytes after encoding
- $K$ is the number of data bytes before encoding
- $T$ is the number of data bytes which can be corrected

The following polynomials [Equation (20) and Equation (21)] are used for the systematic code:

- Code Generator Polynomial: $x) = (x + \lambda^0)(x + \lambda^1)(x + \lambda^2)\ldots(x + \lambda^{2T-1}), \lambda = 02_H$  

- Field Generator Polynomial: $p(x) = x^8 + x^4 + x^3 + x^2 + 1$  

This code is shortened and punctured to enable variable block sizes and variable error-correction capability. When a block is shortened to $K'$ data bytes, add $239-K'$ zero bytes as a prefix. After encoding discard these $239-K'$ zero bytes. When a codeword is punctured to permit $T'$ bytes to be corrected, only the first $2T'$ of the total 16 parity bytes shall be employed. The bit/byte conversion shall be MSB first.
Each RS block is encoded by the binary convolutional encoder, which shall have native rate of 1/2, a constraint length equal to 7, and shall use the generator polynomials codes shown in Equation (22) to derive its two code bits.

\[
G_1 = 171_{\text{OCT}} \quad \text{FOR } X \\
G_2 = 133_{\text{OCT}} \quad \text{FOR } Y \tag{22}
\]

The generator is depicted in Figure 202.

![Convolutional encoder of rate 1/2](image)

Puncturing patterns and serialization order that shall be used to realize different code rates are defined in Table 249. In the table, “1” means a transmitted bit and “0” denotes a removed bit, whereas \( X \) and \( Y \) are in reference to Figure 202.

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

The encoding is performed by first passing the data in block format through the RS encoder and then passing it through a convolutional encoder. A single 0x00 tail byte is appended to the end of each burst. This tail byte shall be appended after randomization. In the RS encoder, the redundant bits are sent before the input bits, keeping the 0x00 tail byte at the end of the allocation. To ensure that the number of bits after the convolutional encoder is divisible by \( N_{\text{chps}} \) as specified in Table 258 in 8.3.3.3, zero (0b0) pad bits are...
added after the zero tail bits before the encoder. The zero pad bits are not randomized. Note that this situation can occur only in subchannelization. In this case, the RS encoding is not employed.

Table 250 gives the block sizes and the code rates used for the different modulations and code rates. As 64-QAM is optional for license-exempt bands, the codes for this modulation shall only be implemented if the modulation is implemented.

</tbody>
</table>

When subchannelization is applied, the FEC shall bypass the RS encoder and use the Overall Coding Rate as indicated in Table 250 as CC Code Rate. The Uncoded Block Size and Coded Block size may be computed by multiplying the values listed in Table 250 by the number of allocated subchannels divided by 16.

In the case of BPSK modulation, the RS encoder should be bypassed.

8.3.3.2.2 Block turbo coding (BTC) (optional)

BTC is based on the product of two simple component codes, which are binary extended Hamming codes or parity check codes from the set depicted in Table 251.

<table>
<thead>
<tr>

</table>

The component codes are used in a two-dimensional matrix form, which is depicted in Figure 203. The \(k_x\) information bits in the rows are encoded into \(n_x\) bits, by using the component block \((n_x, k_x)\) code specified for the respective composite code. After encoding the rows, the columns are encoded using a block code \((n_y, k_y)\), where the check bits of the first code are also encoded. The overall block size of such a product code is \(n = n_x \times n_y\), the total number of information bits \(k = k_x \times k_y\) and the code rate is \(R = R_x \times R_y\), where \(R_i = k_i/n_i\), \(i = x, y\). The Hamming distance of the product code is \(d = d_x \times d_y\). Data bit ordering for the composite BTC matrix is defined so that the first bit in the first row is the LSB, and the last data bit in the last data row is the MSB.

Transmission of the block over the channel shall occur in a linear fashion, with all bits of the first row transmitted left to right followed by the second row, and so on.

To match a required packet size, BTCs may be shortened by removing symbols from the BTC array. In the two-dimensional case, rows, columns, or parts thereof can be removed until the appropriate size is reached. There are three steps in the process of shortening product codes:

1. **Step 1)** Remove \(I_x\) rows and \(I_y\) columns from the two-dimensional code. This is equivalent to shortening the constituent codes that make up the product code.
2. **Step 2)** Remove \(B\) individual bits from the first row of the two-dimensional code starting with the LSB.
3. **Step 3)** Use if the product code specified from Step 1) and Step 2) has a nonintegral number of data bytes. In this case, the \(Q\) leftover LSB are zero-filled by the encoder. After decoding at the receive end, the decoder shall strip off these unused bits and only the specified data payload is passed to the next higher level in the PHY.

The same process is used for shortening the last code word in a message where the available data bytes do not fill the available data bytes in a code block.

These three processes of code shortening are depicted in Figure 203. In the first two-dimensional BTC, a nonshortened product code is shown. By comparison, a shortened BTC is shown in the adjacent two-dimensional array. The new coded block length of the code is \((n_x - I_x)(n_y - I_y) - B\). The corresponding information length is given as \((k_x - I_x)(k_y - I_y) - B - Q\). Consequently, the code rate is given by Equation (23).

\[
R = \frac{(k_x - I_x)(k_y - I_y) - B - Q}{(n_x - I_x)(n_y - I_y) - B} \quad (23)
\]
Table 253 gives the block sizes, code rates, channel efficiency, and code parameters for the different modulation and coding schemes. As 64-QAM is optional for license-exempt bands, the codes for this modulation shall only be implemented if the modulation is implemented.

</table>

When subchannelization is used, the coding block size is limited to blocks at least 96 bits in length. The number of bits is calculated as shown in Equation (24).

\[
\frac{N_{full}}{16} = N_{Sub}
\]  

where

- \(N_{full}\) is number of bits for 16-subchannel (full) mode
- \(N_{Sub}\) is number of active subchannels (1–16)

Table 254 gives the block sizes, code rates, and code parameters for the case of subchannelization.
8.3.3.2.3 Convolutional turbo codes (CTC) (optional)

8.3.3.2.3.1 CTC encoder

The CTC encoder, including its constituent encoder, is depicted in Figure 204. It uses a double binary Circular Recursive Systematic Convolutional code. The bits of the data to be encoded are alternately fed to \( A \) and \( B \), starting with the MSB of the first byte being fed to \( A \). The encoder is fed by blocks of \( k \) bits or \( N \) couples (\( k = 2 \times N \) bits). For all the frame sizes, \( k \) is a multiple of 8 and \( N \) is a multiple of 4. \( N \) shall be limited to: \( N \leq 8 \leq 1024 \). For subchannelization mode, the coding block size is limited to blocks at least 48 bits in length, and no more than 1024 bits in length. In addition, \( k \) cannot be a multiple of 7.

The polynomials defining the connections are described in octal and symbol notations as follows:

- For the feedback branch: 0xB, equivalently \( 1 + D + D^3 \) (in symbolic notation)
- For the \( Y \) parity bit: 0xD, equivalently \( 1 + D^2 + D^3 \)

First, the encoder (after initialization by the circulation state \( S_{C_1} \), see 8.3.3.2.3.3) is fed the sequence in the natural order (position 1) with the incremental address \( i = 0 \ldots N – 1 \). This first encoding is called \( C_1 \) encoding. Then the encoder (after initialization by the circulation state \( S_{C_2} \), see 8.3.3.2.3.3) is fed by the interleaved sequence (switch in position 2) with incremental address \( j = 0 \ldots N – 1 \). This second encoding is called \( C_2 \) encoding.

The order that the encoded bit shall be fed into the interleaver (8.3.3.3) is as follows:
where $M$ is the number of parity bits.

Table 255 gives the block sizes, code rates, channel efficiency, and code parameters for the different modulation and coding schemes. As 64-QAM is optional for license-exempt bands, the codes for this modulation shall only be implemented if the modulation is implemented.

### Table 255—Optional CTC channel coding per modulation

<td>17</td>
</tr>
<tr>
<td>64-QAM</td>
<td>$27 \times N_{sub}$</td>
<td>3/4</td>
<td>17</td>
</tr>
</tbody>
</table>

In Table 255, $N_{sub}$ denotes the number of subchannels of the allocation in which the encoded data will be transmitted. The data block size (in bytes per OFDM symbol) may be calculated as $N/4$. Further, $P_1$ equals $3N/4$.

#### 8.3.3.2.3.2 CTC interleaver

The interleaver requires the parameters $P_0$, shown in Table 255.
The two-step interleaver shall be performed as follows:

1. **Step 1:** Switch alternate couples.
   
   for \( j = 1 \ldots N \)
   
   if \( (j \mod 2 = 0) \) let \((B,A) = (A,B)\) (i.e., switch the couple)

2. **Step 2:** \( P_i(j) \).
   
   The function \( P_i(j) \) provides the interleaved address \( i \) of the consider couple \( j \).
   
   for \( j = 1 \ldots N \)
   
   switch \( j \mod 4 \):
   
   case 0 or 1:
     \( i = (P_0 \cdot j + 1) \mod N \)
   
   case 2:
     \( i = (P_0 \cdot j + 1 + N/4) \mod N \)
   
   case 3:
     \( i = (P_0 \cdot j + 1 + N/2 + P_1) \mod N \)

### 8.3.3.2.3 Determination of CTC circulation states

The state of the encoder is denoted \( S \) \((0 \leq S \leq 7)\) with \( S \) the value read binary (left to right) out of the constituent encoder memory (see Figure 204). The circulation states \( S_{c1} \) and \( S_{c2} \) are determined by the following operations:

1. **Step 1:** Initialize the encoder with state 0. Encode the sequence in the natural order for the determination of \( S_{c1} \) or in the interleaved order for determination of \( S_{c2} \). In both cases, the final state of the encoder is \( S_{0N-1} \).
2. **Step 2:** According to the length \( N \) of the sequence, use Table 256 to find \( S_{c1} \) or \( S_{c2} \).

### 8.3.3.2.4 CTC puncturing

The three code rates are achieved through selectively deleting the parity bits (puncturing). The puncturing patterns are identical for both codes \( C_1 \) and \( C_2 \). See Table 257.

### 8.3.3 Interleaving

All encoded data bits shall be interleaved by a block interleaver with a block size corresponding to the number of coded bits per the allocated subchannels per OFDM symbol, \( N_{chps} \). The interleaver is defined by a two step permutation. The first ensures that adjacent coded bits are mapped onto nonadjacent subcarriers. The second permutation insures that adjacent coded bits are mapped alternately onto less or more significant bits of the constellation, thus avoiding long runs of lowly reliable bits.
Let $N_{cpc}$ be the number of coded bits per subcarrier, i.e., 1, 2, 4 or 6 for BPSK, QPSK, 16-QAM, or 64-QAM, respectively. Let $s = \text{ceil}(N_{cpc}/2)$. Within a block of $N_{cbps}$ bits at transmission, let $k$ be the index of the coded bit before the first permutation; $m_k$ be the index of that coded bit after the first and before the second permutation; and let $j_k$ be the index after the second permutation, just prior to modulation mapping.

The first permutation is defined by Equation (25).

$$m_k = (N_{cbps}/12) \cdot k_{\text{mod}12} + \text{floor}(k/12) \quad k = 0, 1, \ldots, N_{cbps} - 1$$

The second permutation is defined by Equation (26).

$$j_k = s \cdot \text{floor}(m_k/s) + (m_k + N_{cbps} - \text{floor}(12 \cdot m_k/N_{cbps}))_{\text{mod}(s)} \quad k = 0, 1, \ldots, N_{cbps} - 1$$

The de-interleaver, which performs the inverse operation, is also defined by two permutations. Within a received block of $N_{cbps}$ bits, let $j$ be the index of a received bit before the first permutation; $m_j$ be the index of that bit after the first and before the second permutation; and let $k_j$ be the index of that bit after the second permutation, just prior to delivering the block to the decoder.

The first permutation is defined by Equation (27).

$$m_j = s \cdot \text{floor}(j/s) + (j + \text{floor}(12 \cdot j/N_{cbps}))_{\text{mod}(s)} \quad j = 0, 1, \ldots, N_{cbps} - 1$$

The second permutation is defined by Equation (28).

$$k_j = 12 \cdot m_j - (N_{cbps} - 1) \cdot \text{floor}(12 \cdot m_j/N_{cbps}) \quad j = 0, 1, \ldots, N_{cbps} - 1$$

The first permutation in the de-interleaver is the inverse of the second permutation in the interleaver, and conversely.

Table 258 shows the bit interleaver sizes as a function of modulation and coding.

The first bit out of the interleaver shall map to the MSB in the constellation.

### 8.3.3.4 Modulation

#### 8.3.3.4.1 Data modulation

After bit interleaving, the data bits are entered serially to the constellation mapper. BPSK, Gray-mapped QPSK, 16-QAM, and 64-QAM as shown in Figure 205 shall be supported, whereas the support of 64-QAM is optional for license-exempt bands. The constellations (as shown in Figure 205) shall be normalized by

---

**Table 257—CTC puncturing ($S_C$)**

<table>
<thead>
<tr>
<th>Rate $R_p/(R_n+1)$</th>
<th>Y</th>

<td>1</td>
</tr>
</tbody>
</table>
multiplying the constellation point with the indicated factor $c$ to achieve equal average power. For each
modulation, $b_0$ denotes the LSB.

Per-allocation adaptive modulation and coding shall be supported in the DL. The UL shall support
different modulation schemes for each SS based on the MAC burst configuration messages coming from the BS.
Complete description of the MAC/PHY support of adaptive modulation and coding is provided in 6.3.7.
The constellation-mapped data shall be subsequently modulated onto all allocated data subcarriers in order of increasing frequency offset index. The first symbol out of the data constellation mapping shall be modulated onto the allocated subcarrier with the lowest frequency offset index.

### 8.3.3.4.2 Pilot modulation

Pilot subcarriers shall be inserted into each data burst in order to constitute the Symbol and they shall be modulated according to their carrier location within the OFDM symbol. The PRBS generator depicted hereafter shall be used to produce a sequence, \( w_k \). The polynomial for the PRBS generator shall be \( X^{11} + X^9 + 1 \). See Figure 206.

![Figure 206—PRBS generator for pilot modulation](image)

The value of the pilot modulation for OFDM symbol \( k \) is derived from \( w_k \). On the DL, the index \( k \) represents the symbol index relative to the beginning of the DL subframe. For bursts contained in the STC zone when the FCH-STC is present, index \( k \) represents the symbol index relative to the beginning of the STC zone. In the DL subchannelization zone, the index \( k \) represents the symbol index relative to the beginning of the burst. On the UL, the index \( k \) represents the symbol index relative to the beginning of the burst. On both UL and DL, the first symbol of the preamble is denoted by \( k = 0 \). The initialization sequences that shall be used on the DL and UL are shown in Figure 206. On the DL, this shall result in the sequence 111111111100000000110... where the third 1, i.e., \( w_2 = 1 \), shall be used in the first OFDM DL symbol following the frame preamble. For each pilot (indicated by frequency offset index), the BPSK modulation shall be derived as shown in Equation (29) and Equation (30).

\[
\begin{align*}
DL: \ c_{-88} &= c_{-38} = c_{63} = c_{88} = 1 - 2w_k \\
&= c_{-63} = c_{-13} = c_{13} = c_{38} = 1 - 2w_k \\
UL: \ c_{-88} &= c_{-38} = c_{13} = c_{38} = c_{63} = c_{88} = 1 - 2w_k \\
&= c_{63} = c_{-13} = 1 - 2w_k
\end{align*}
\]

#### (29)  

#### (30)

### 8.3.3.4.3 Rate ID encodings

Rate IDs, which indicate modulation and coding to be used in the first DL burst immediately following the FCH, are shown in Table 259. The Rate ID encoding is static and cannot be changed during system operation.

### 8.3.3.5 Example OFDM UL RS-CC encoding

To illustrate the use of the RS-CC encoding, three examples are provided, each of one burst of OFDM UL data, illustrating each process from randomization through subcarrier modulation.

-100: -1 1, -99: -1 -1, -98: -1 -1, -37: 1 1, -36: -1 -1, -35: -1 1, 1: -1 -1, 2: 1 1, 3: -1 1, 64: -1 1, 65: 1 1, 66: 1 -1

2nd data symbol:

-100: -1 -1, -99: -1 -1, -98: 1 -1, -37: 1 1, -36: 1 1, 1: -1 1, 2: 1 1, 3: 1 1, 64: -1 -1, 65: -1 1, 66: -1 1

3rd data symbol:

-100: 1 -1, -99: -1 -1, -98: 1 1, -37: 1 1, -36: 1 -1, 1: -1 1, 2: 1 1, 3: -1 -1, 64: -1 -1, 65: -1 1, 66: 1 1

4th data symbol:

-100: 1 1, -99: -1 -1, -98: 1 1, -37: 1 -1, -36: 1 -1, 1: 1 1, 2: -1 -1, 3: 1 -1, 64: 1 1, 65: 1 -1, 66: -1 -1

5th data symbol:

-100: -1 -1, -99: -1 1, -98: 1 -1, -37: 1 -1, 1: 1 1, 2: -1 1, 3: -1 1, 64: -1 1, 65: 1 1, 66: -1 1

Note that the above QPSK values are to be normalized with a factor \( 1/\sqrt{2} \) as indicated in Figure 205.

8.3.3.6 Preamble structure and modulation

All preambles are structured as either one or two OFDM symbols. The OFDM symbols are defined by the values of the composing subcarriers. Each of those OFDM symbols contains a cyclic prefix. The length of the cyclic prefix is the same as the CP for data OFDM symbols.
IEEE Std 802.16-2009

IEEE STANDARD FOR LOCAL AND METROPOLITAN AREA NETWORKS—

The first preamble in the DL PHY PDU, as well as the initial ranging preamble, consists of two consecutive
OFDM symbols. The first OFDM symbol uses only subcarriers the indices of which are a multiple of 4. As
a result, the time domain waveform of the first symbol consists of four repetitions of 64-sample fragment,
preceded by a CP. The second OFDM symbol utilizes only even subcarriers, resulting in time domain
structure composed of two repetitions of a 128-sample fragment, preceded by a CP. The time domain
structure is exemplified in Figure 207. This combination of the two OFDM symbols is referred to as the long
preamble.

(31)
The frequency domain sequence for the 4 times 64 sequence P4x64 is defined by Equation (32).
⎧ 2 ⋅ 2 ⋅ conj ( P ALL ( k ) )
P 4x64 ( k ) = ⎨
0
⎩

k mod4 = 0

(32)

k mod4 ≠ 0

In Equation (32), the factor of 2 equates the Root-Mean-Square (RMS) power with that of the data section.
The additional factor of 2 is related to the 3 dB boost.
The frequency domain sequence for the 2 times 128 sequence PEVEN is defined by Equation (33).
⎧ 2 ⋅ P ALL ( k )
P EVEN ( k ) = ⎨
0
⎩

In PEVEN, the factor of

k mod2 = 0
k mod2 ≠ 0

(33)

2 is related to the 3 dB boost.

In the UL, when the entire 16 subchannels are used, the data preamble, as shown in Figure 208 consists of
one OFDM symbol utilizing only even subcarriers. The time domain waveform consists of 2 times 128
samples preceded by a CP. The subcarrier values shall be set according to the sequence PEVEN. This
preamble is referred to as the short preamble. This preamble shall be used as burst preamble on the DL
bursts when indicated in the DL-MAP IE.

P AAS ( k ) = ⎨
⎩ conj { P ALL ( k + 2 – m ) }

k mod 4 ≠ m
k mod 4 = m

(36)

In the UL, when subchannelization transmissions are employed, the data preamble consists of a 256 sample
sequence preceded by a CP whose length is the same as the cyclic prefix for data OFDM symbols. This
preamble is referred to as the subchannelization preamble. The frequency domain sequence for the 256
samples is defined by PSUB. Preamble subcarriers that do not fall within the allocated subchannels shall be
set to zero.
PSUB(-100:100) = {1+j, 1+j, -1-j, 1+j, -1+j, 1+j, 1+j, 1+j, -1-j, -1-j, 1-j, -1-j, 1-j, 1+j, 1-j, 1+j, 1+j, -1-j, -1j, 1+j, 1-j, 1+j, -1-j, 1+j, 1+j, 1+j, 1+j, -1-j, 1+j, -1+j, 1+j, 1+j, 1+j, -1-j, -1-j, 1-j, -1-j, 1-j, 1+j, 1-j, 1+j, 1+j, -1-j, -1-j, 1+j, 1-j, 1+j, -1-j, 1+j, 1+j, 1+j, 1+j, -1-j, 1+j, -1+j, 1+j,

In the case that the UL allocation contains midambles, the midambles shall consist of one OFDM symbol and shall be identical to the preamble used with the allocation.

UL preambles and midambles may be cyclically delayed by an integer number of samples. This is indicated by the UL-Physical modifier IE (8.3.6.3.7).

8.3.4 Transmission convergence sublayer (TCS)

The TCS, as described in 8.1.4.3, is an optional mechanism for the OFDM PHY and can be enabled on a per-burst basis for both UL and DL through the DIUC/UIUC definitions in the DCD/UCD messages, respectively. The TCS_ENABLE parameter is coded as a TLV tuple as defined in 11.4.2 (i.e., DCD burst profile encodings) and 11.3.1.1 (i.e., UCD burst profile encodings).

At SS initialization, the TC sublayer capability is negotiated between the BS and SS through SBC-REC/SBC-RSP messages as an OFDM PHY specific parameter. The TC sublayer capability parameter is coded as a TLV tuple as defined in 11.8.3.4.4.

8.3.5 Frame structure

8.3.5.1 PMP

In licensed bands, the duplexing method shall be either FDD or TDD. FDD SSs may be H-FDD. In license-exempt bands, the duplexing method shall be TDD. Examples of TDD and FDD frame structures are shown in Figure 209 and Figure 210, respectively.

The frame interval contains transmissions (PHY PDUs) of BS and SSs, gaps and guard intervals.

The OFDM PHY supports a frame-based transmission. A frame consists of a DL subframe and an UL subframe. A DL subframe consists of only one DL PHY PDU. A UL subframe consists of contention intervals scheduled for initial ranging and BR purposes and one or multiple UL PHY PDUs, each transmitted from a different SS.

A DL PHY PDU starts with a long preamble, which is used for PHY synchronization. The preamble is followed by a FCH burst. The FCH burst is one OFDM symbol long and is transmitted using BPSK rate 1/2 with the mandatory coding scheme. The FCH contains DL_Frame_Prefix to specify burst profile and length of one or several DL bursts immediately following the FCH. See Figure 261 for the format of the DL_Frame_Prefix. A DL-MAP message, if transmitted in the current frame, shall be the first MAC PDU in the burst following the FCH. An UL-MAP message shall immediately follow either the DL-MAP message (if one is transmitted) or the DLFP. If UCD and DCD messages are transmitted in the frame, they shall immediately follow the DL-MAP and UL-MAP messages. Although burst #1 contains broadcast MAC control messages, it is not necessary to use the most robust well-known modulation/coding. A more efficient modulation/coding may be used if it is supported and applicable to all the SSs of a BS.

The FCH is followed by one or multiple DL bursts. Each DL burst consists of an integer number of OFDM symbols. Location and profile of the first DL burst is specified in the DL frame prefix (DLFP). The location and profile of the maximum possible number of subsequent bursts shall also be specified in the DLFP. At least one full DL-MAP shall be broadcast in burst #1 within the Lost DL-MAP Interval specified in Table 554. Location and profile of other bursts are specified in DL-MAP. Profile is specified either by a 4-bit Rate_ID (for the first DL burst) or by DIUC. The DIUC encoding is defined in the DCD messages. HCS field occupies the last byte of DLFP. If there are unused IEs in DLFP, the first unused IE shall have all fields encoded as zeros.
The DL Subframe may optionally contain an STC zone in which all DL bursts are STC encoded. If an STC zone is present, the last used IE in the DLFP shall have DIUC = 0 (see Table 275) and the IE shall contain information on the start time of the STC zone (see Table 279). The STC zone ends at the end of the frame.

The STC zone starts from a preamble. The BS can choose between the following two modes of operation:

a) **No FCH-STC present.** If the regular DL-MAP describes allocations in the STC zone, then the STC zone shall start with an STC preamble that may be immediately followed by encoded PHY bursts, with no FCH-STC present.

b) **FCH-STC present.** If the DL-MAP does not describe allocations in the STC zone, then the STC zone shall start with an STC preamble that is immediately followed by an STC-encoded FCH-STC burst, which is one symbol with the same payload format as specified in Table 260. The FCH-STC burst is transmitted at BPSK rate 1/2. It is followed by one or several STC-encoded PHY bursts. The first burst in the STC zone may contain a DL-MAP applicable only to the STC zone, in which the DL IEs’ start times refer to the beginning of the STC zone, including preamble. If DL-MAP is present, it shall be the first MAC PDU in the payload of the burst. The STC zone may also contain an UL-MAP as well as DCD and UCD messages. The UL-MAP, if present, shall not duplicate or overlap any unicast allocations made in the regular UL-MAP, and the allocation start time shall refer to the beginning of the STC zone. The UL-MAP, if present, shall not contain duplicate or overlapping unicast allocations (defined within same or any other UL-MAP). Contention region allocations may be duplicated, in which case they shall fully overlap. The randomizer and pilot modulation shall be reinitialized at the beginning of the STC zone.

The SS will be able to determine that there is no STC data allocation in frame K-1 STC zone by determining that there has been no STC zone in the previous frame K-2.

The DL subframe may optionally contain a DL subchannelization zone as described in 8.3.5.1.1.

With the OFDM PHY, a PHY burst, either a DL PHY burst or an UL PHY burst, consists of an integer number of OFDM symbols, carrying MAC messages, i.e., MAC PDUs. To form an integer number of OFDM symbols, unused bytes in the burst payload may be padded by the bytes 0xFF. Then the payload shall be randomized, encoded, and modulated using the burst PHY parameters specified by this standard. If an SS does not have any data to be transmitted in an UL allocation, the SS shall transmit an UL PHY burst (as specified in 6.3.3.7) that may contain a BR header as defined in Figure 23, with BR = 0 and its basic CID. If the allocation is large enough, an AAS-enabled SS may also provide an AAS Feedback Response (AAS-FBCK-RSP) message (6.3.2.3.35). An SS shall transmit during the entirety of all of its UL allocations, using the standard padding mechanism (6.3.3.7) to fill allocations if necessary.

In each TDD frame (see Figure 209), the TTG and RTG shall be inserted between the DL and UL subframe and at the end of each frame, respectively, to allow the BS to turn around.
In TDD and H-FDD systems, SS allowances shall be made by a Tx-Rx turnaround gap SSTTG and by a Rx-Tx turnaround gap SSRTG. The BS shall transmit DL bursts intended for an SS so that the end of any DL burst shall not be transmitted to the SS later than (SSRTG + RTD) before its scheduled UL allocation and the beginning of any DL burst to the SS shall not be transmitted to the SS earlier than (SSTTG – RTD) after the end of its scheduled UL allocation, where RTD denotes round-trip delay. The parameters SSRTG and SSTTG are capabilities provided by the SS to BS upon request during network entry (see 11.8.3.1).

Because the optional STC and AAS zones may contain UL-MAPs, along with the UL-MAP transmitted in the mandatory part of the frame, and because the allocation start time for frames may vary from one frame to the next, there is a possibility that UL-MAPs from two frames, or from different zones, may describe overlapping time intervals. Where MAP IEs (contained in either a AAS-DLFP or a UL-MAP) describe overlapping time intervals with MAP IEs from another UL-MAP (or AAS-DLFP), then an SS shall interpret and use those from the most recently received map. MAP IEs that do not conflict with MAP IEs received in earlier UL-MAPs (or AAS-DLFP) shall augment the UL-MAP.

**HCS**

An 8-bit header check sequence used to detect errors in the DL Frame Prefix. The generator polynomial is \( g(D) = D^8 + D^2 + D + 1 \). The transmitter shall take all the bytes in the DL Frame Prefix except the byte reserved for the HCS and divide them by \( g(x) \) and use the remainder as HCS code. At the receiver, dividing the DL Frame Prefix by \( g(x) \) then gives the remainder 0 if correct. (Example: BS_ID = 0x0319B812A9B8 (4LSB = 0x8), Frame_Number = 187662 (4LSB = 0x8), Configuration = 159 (4LSB = 0xf), Reserved = 0x0, Rate_ID = 1 (0x1), Length = 204 (0x0CC), DLFP_IE(1) DIUC = 1 (0x1), DLFP_IE(1) Midamble Present = 1 / Burst_Length = 50 (0x832), all following DLFP_IEs = 0 (2 times 0x0000). Encode byte sequence [0x8EF010] and obtain 0x30 as the HCS byte.)
8.3.5.1.1 PMP DL subchannelization zone

The DL subframe may optionally contain a DL subchannelization zone. This zone is marked by a DL SUBCH IE in the DL-MAP.

The DL subchannelization zone is shown in Figure 211.

The zone commences with a subchannelized preamble followed by a subchannelized FCH burst. The FCH is transmitted using QPSK-1/2. The FCH is transmitted over 1/4 of the bandwidth. The carrier allocation is as given in Table 248 (regarding OFDM symbol parameters).

The subchannel index of the FCH shall be one of the codes 0b00100, 0b01100, 0b10100, or 0b11100. The subchannel index should preferably be provisioned by the operator to avoid illumination of an area by BSs using the same frequency channel with the same subchannel index. If not provisioned, the subchannel index shall, by default, be derived from the 2 LSBs of the BSID as in Table 261.

The FCH contains the SBCH_DLFP, which points to the control subchannel (CCH), and contains the profile and length of the first burst in it. The SBCH_DLFP is shown in Table 262.
The FCH is followed by subchannelized traffic on allocated subchannels. The subcarrier allocation of the subchannels is given in Table 248. Bursts in the DL subchannelized zone shall contain midambles when indicated in the midamble repetition field.

</tbody>
</table>

**Start Time**

This field indicates the start time in units of symbol duration, relative to the beginning of the subsequent DL subchannelized zone (including preamble).

A BS shall assume that the MS is not capable of receiving more than one burst in a single frame. Therefore DL allocations contained in SBCH DL-MAP IEs in the CCH shall point to future frames. When an allocation is present for a given MS, the BS shall assume that the MS may not be capable of demodulating the CCH in that frame, and therefore not include any SBCH DL-MAP IEs or UL-MAP IEs for that MS.

### 8.3.5.2 PMP-AAS Zone

DL transmission to an SS or group of SSs consists of two fractions. The first fraction of the transmission consists of one or several repetitions of a short preamble followed by AAS-FCH symbol (Figure 212). The second fraction is called Body.

The randomizer shall be reinitialized with the sequence 1 0 0 1 0 1 0 1 0 0 0 0 0 0 for all the AAS-FCH bursts and not initialized for the first burst of the body. It is then reinitialized as specified in Figure 200 for subsequent bursts.

AAS-FCH payload is called “AAS DL Frame Prefix” (AAS_DLFP). AAS-FCH shall be transmitted at the lowest possible modulation. Each pair preamble–AAS-FCH may be transmitted either at narrow beam or at wide beam. Optionally, the same preamble–AAS-FCH pair may be repeated at several beams thus implementing space diversity. In the case when AAS-FCH is repeated for diversity, all copies have the same content and therefore soft combining might be employed at the SS receiver.

AAS_DLFP contains information (DL IEs or UL IEs) on location and transmission rate of PHY bursts. There is a possibility of more than one concatenated DL PHY burst, each one described by a DL IE. UL IEs specify either UL PHY burst (a single burst per SS) or contention region for initial ranging or bandwidth requesting. The DL IEs and UL IEs in each AAS_DLFP shall appear in the same order as the allocations to
which they refer. The DL IEs and UL IEs described in the AAS portion of the zone shall not be described in the broadcast DL-MAP and UL-MAP.

Body may be transmitted at a directed beam and may start either immediately after AAS-FCH or at some distance. In the latter case, it shall start from a preamble. The payload of the burst may contain private DL-MAP and/or UL-MAP messages.

Alternatively, AAS_DLFP may contain UL IEs. There are two options:

a) A single UL IE
b) “Compressed” UL IE, which contains a network entry allocation and a regular allocation

The minimum time between an UL IE and the corresponding UL burst shall be equal to the relevance time of an UL-MAP as described in 6.3.7.5.

An example of AAS zone layout is shown at Figure 212.

![](image)

**Figure 212—Structure of AAS Zone**

The structure of AAS_DLFP is specified in Table 264.

The format for AAS_DLFP_DL IE is shown in Table 265.

The format for AAS_DLFP_UL IE is shown in Table 266.

AAS COMP UL IE shall be used to specify two UL allocations. One of them shall be for NW entry; another one is either unicast allocation or multicast/broadcast polling allocation. See Table 267.

The format for AAS NW Entry Response IE is shown in Table 269.

8.3.5.3 Frame duration codes

Table 270 indicates the specific frame durations that are allowed. The frame duration used can be determined by the periodicity of the frame start preambles. Once a specific frame duration has been selected by the BS, it should not be changed. Changing the frame duration shall force all SSs to resynchronize to the BS.

<table>

8.3.5.4 Burst profile format

Table 271 defines the format of the Downlink_Burst_Profile, which is used in the DCD message (6.3.2.3.1). The Downlink_Burst_Profile is encoded with a Type of 1, an 8-bit length, and a 4-bit DIUC. The DIUC field is associated with the DL burst profile. The DIUC value is used in the DL-MAP message and in DLFP to specify the Burst Profile to be used for a specific DL burst.

Table 271—OFDM Downlink_Burst_Profile format

<table>

</table>

**8.3.6 Map message fields and IEs**

**8.3.6.1 DL-MAP PHY synchronization field**

The PHY synchronization field of the DL-MAP message is structured as shown in Table 273.

**Table 273—OFDM PHY synchronization field**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synchronization_field</td>
<td>—</td>
<td>The OFDM PHY synchronization field is empty (zero bytes long).</td>
</tr>
</tbody>
</table>

**8.3.6.2 DL-MAP IE format**

DL-MAP IEs have the format listed in Table 274.

**Connection Identifier (CID)**

Represents the assignment of the IE to a broadcast, multicast, or unicast address.

If the broadcast or multicast CID is used, then it is possible to concatenate unicast MAC PDUs (with different CIDs) into a single DL burst. During a broadcast or multicast DL burst, it is the responsibility of the BS to ensure that any bursts sent to an H-FDD SS do not overlap (in time; taking SSTTG and SSRTG into account) any UL allocations for that SS. An H-FDD SS for which a DL MAP IE and UL MAP IE overlap in time shall use the UL allocation and discard DL traffic during the overlapping period.

**DIUC**

A 4-bit DIUC shall be used to define the burst type associated with that time interval. Burst Descriptor shall be included into DCD message for each DIUC used in the DL-MAP except those associated with Gap, End of Map, and Extended. The DIUC shall be one of the values defined in Table 275.
Preamble present

If set, the indicated burst shall start with the short preamble.

Start Time

If transmitted in a private map (for compressed private map, see 8.3.6.6; for reduced private map, see 8.3.6.7) within an AAS zone, this field indicates the start time, in units of symbol duration, relative to the beginning of the subsequent AAS zone (including preamble) where the DL-MAP message is transmitted. If transmitted in a compressed private map (see 8.3.6.6), this field indicates the start time, in units of symbol duration, relative to the beginning of the subsequent DL frame (including preamble). For a DL-MAP in the STC zone, this field indicates the start time in units of symbol duration, relative to the start of the first symbol of the STC zone (including preamble). The end of the last allocated burst is indicated by allocating an End of Map burst (DIUC = 14) with zero duration. The time instants indicated by the Start Time values are the transmission times of the first symbol of the burst including (if present) any preamble.

### 8.3.6.2.1 DIUC allocations

Table 275 contains the DIUC values used in DL-MAP_IE().

#### Table 275—OFDM DIUC values

<table>
<thead>
<tr>
<th>DIUC</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>STC zone</td>
</tr>
<tr>
<td>1–11</td>
<td>Burst Profiles</td>
</tr>
<tr>

</tr>
<tr>
<td>13</td>
<td>Gap</td>
</tr>
<tr>
<td>14</td>
<td>End of Map</td>
</tr>
<tr>
<td>15</td>
<td>Extended DIUC</td>
</tr>
</tbody>
</table>
The Gap Downlink Burst Profile (DIUC = 13) indicates that the BS does not transmit (a silent interval in DL transmission) and the SS shall ignore the received signal.

### 8.3.6.2.2 DL-MAP Extended IE format

A DL-MAP IE entry with a DIUC = 15 indicates that the IE carries special information and conforms to the structure shown in Table 276. A station shall ignore an extended IE entry with an extended DIUC value for which the station has no knowledge. In the case of a known extended DIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

#### Table 276—DL-MAP Extended IE format

<table>
<thead>
<tr>

<td>Length in bytes of Unspecified Data field</td>
</tr>
<tr>
<td>Unspecified data</td>
<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

#### 8.3.6.2.3 Channel Measurement IE format

An extended IE with an extended DIUC = 0x00 is issued by the BS to request a channel measurement (see 6.3.2.3.33). The Channel_Measurement_IE() shall be followed by the End of Map IE (DIUC = 14).

#### Table 277—OFDM Channel measurement IE format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

#### 8.3.6.2.4 DL-MAP AAS IE format

Within a frame, the switch from non-AAS to AAS-enabled traffic is marked by using the DIUC = 15 with the AAS_IE() to indicate that the subsequent allocations, until the start of the first UL-MAP allocation using TDD, and until the end of the frame using FDD, shall be for AAS traffic. When used, the CID in the
DL-MAP_IE() shall be set to the Broadcast CID. Subsequent AAS PHY bursts shall all start with the short preamble.

**Table 278—OFDM AAS DL IE format**

<table>
<thead>
<tr>

<td>Length = 0x00</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**8.3.6.2.5 DL-MAP STC IE format**

In the DL-MAP, an STC enabled BS (see 8.3.8) may transmit DIUC = 15 with the STC_IE() to indicate that the subsequent allocations shall be STC encoded. No preceding DL allocations shall be STC encoded and all subsequent DL allocations until the end of the frame shall be STC encoded. After this allocation, the BS shall transmit from both its antennas until the end of the frame. The first DL allocation following the STC IE shall contain a preamble. The number of OFDM data symbols between two preambles and the number of OFDM data symbols between the last preamble and the end of the DL subframe shall be even.

**Table 279—OFDM STC IE format**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Length</td>
<td>4</td>
<td>Length = 0x00</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**8.3.6.2.6 DL-MAP Concurrent Transmission IE format**

In the DL-MAP, a BS may transmit UIUC = 15 with the DL_Concurrent_IE() to specify one of a set of parallel DL bursts for transmission. This format explicitly specifies the duration of the corresponding DL burst. A preamble may precede the DL burst specified by this IE.
A 4-bit DIUC shall be used to define the burst type associated with that time interval. Burst Descriptor shall be included into DCD message for each DIUC used in the DL-MAP. The DIUC shall be one of the Burst Profile values (1–12) defined in Table 275.

### Duration
Indicates the duration of the burst, in units of OFDM symbols. The duration is inclusive of the preamble contained in the allocation, if present.

#### 8.3.6.2.7 DL-MAP Physical Modifier IE format

The Physical Modifier IE (see Table 281) indicates that the subsequent bursts utilize a preamble, if present, which is cyclically delayed in time by $M$ samples. Equation (38) defines the waveform transmitted during these training symbols. The PHYMOD DL IE can appear anywhere in the DL map, and it shall remain in effect until another PHYMOD DL IE is encountered, or until the end of the DL map.

Only stations that are allocated in bursts specified by a DL-MAP concurrent transmission IE format (8.3.6.2.6) shall receive the timely shifted preamble.

### Table 281—OFDM DL-MAP Physical Modifier IE format

<table>
<thead>
<tr>

<td>Length = 1</td>
</tr>
<tr>
<td>Preamble Time Shift</td>
<td>8</td>
<td>—</td>
</tr>
<tr>
<td></td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

The parameter indicating how many samples of cyclic shift are introduced into the training symbols of the following bursts [$M$ in Equation (38)].
8.3.6.2.8 DL-MAP Dummy IE format

An SS shall be able to decode the DL-MAP Dummy IE (see Table 282). A BS shall not transmit this IE (unless under test). An SS may skip decoding DL bursts scheduled after the Start Time of this IE within the current frame.

Table 282—OFDM DL-MAP Dummy IE format

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>

<td>—</td>
</tr>
</tbody>
</table>

8.3.6.2.9 DL SUBCH IE format

In the DL-MAP a DL subchannelization enabled BS (see 8.3.5.3) may transmit an extended IE with a DUIC = 0x5 to indicate that subsequent allocations use DL subchannelization. The extended IE conforms to the structure in Table 283.

Table 283—DL SUBCH IE format

<table>
<thead>
<tr>

</tr>
<tr>
<td>Length</td>
<td>4</td>
<td>Length = 0x00</td>
</tr>
<tr>
<td></td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

8.3.6.3 UL-MAP IE format

The UL-MAP IE defines the physical parameters and the start time for UL PHY bursts. The format of UL-MAP elements is shown in Table 284. Appearance of the Extended UIUC, means that the UL-MAP IE contains information that conforms to the format described in 8.3.6.3.4. The BS shall not assign, to any given SS, two or more overlapping subchannelized allocations in time. An H-FDD SS for which a DL MAP IE and UL MAP IE overlap in time shall use the UL allocation and discard DL traffic during the overlapping period.
CID
Represents the assignment of the IE to a unicast, multicast, or broadcast address. When specifically addressed to allocate a bandwidth grant, the CID shall be the Basic CID of the SS.

UIUC
A 4-bit UIUC shall be used to define the type of UL access and the burst type associated with that access. A Burst Descriptor shall be included into an UCD message for each UIUC that is to be used in the UL-MAP. The UIUC shall be one of the values defined in Table 285.

Start Time
Indicates the start time, in units of symbol duration, relative to the Allocation Start Time given in the UL-MAP message. The end of the last allocated burst is indicated by allocating an End of Map burst (CID = 0 and UIUC = 14).

Duration
Indicates the duration, in units of OFDM symbols, of the allocation. The duration is inclusive of the preamble, the midambles and the postamble, contained in the allocation.

Subchannel Index
See Table 248.

Midamble Repetition Interval
Indicates the preamble repetition interval in OFDM symbols. When the last section of burst after the last preamble/midamble is higher than half the midamble repetition interval (i.e., more than 2, 4, 8, for 0b01, 0b10, 0b11), a postamble shall be added at the end of the burst.

8.3.6.3.2 UL-MAP Focused Contention IE format

Table 286 defines the UL-MAP IE for allocation of bandwidth for an SS that requested bandwidth using focused contention reservation requests (see 6.3.6.4). This UL-MAP IE is identified by UIUC = 4 (see Table 285). An SS responding to a bandwidth allocation using the Focused Contention IE shall start its burst with a short preamble (see 8.3.3.6) and use only the most robust mandatory burst profile in that burst.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>

</tr>
<tr>
<td>Contention Code Index</td>
<td>3</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Frame Number Index
Identifies the frame in which the network entry request, which this message responds to, was transmitted. The 4 LSBs of the frame number are used as the frame number index.

Transmit Opportunity Index
Index number of the Tx opportunity (used in the BR) to which this message is responding. The Tx opportunities are numbered from 0x0 to 0x7, where Tx opportunity 0x0 indicates the first Tx opportunity in the frame pointed by the Frame Number Index.
Contention Channel Index
Index number of the Contention Channel (used in the BR) to which this message is responding.

Contention Code Index
Index number of the Contention Code (used in the BR) to which this message is responding.

8.3.6.3.3 Subchannelized Network Entry IE

Table 287 defines the UL-MAP IE for allocation of bandwidth in response to a subchannelized network entry signal (see 8.3.7.2). This UL-MAP IE is identified by UIUC = 13 in the subchannelized section of the UL-MAP. An SS responding to a bandwidth allocation using the Subchannelized Network Entry IE shall start its burst with a subchannelization preamble (see 8.3.3.6) and use only the most robust mandatory burst profile in that burst.

<table>

<td>—</td>
</tr>
<tr>
<td>Contention Subchannel</td>
<td>4</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Frame Number Index
Identifies the frame in which the network entry request, which this message responds to, was transmitted. The 4 LSBs of the frame number are used as the Frame Number Index.

Transmit Opportunity Index
Index number of the Tx opportunity that was used in the network entry, within the frame pointed by the Frame Number Index. The Tx opportunities are numbered from 0x00 to 0x0F, where Tx opportunity 0x00 indicates the first Tx opportunity in the frame pointed by the frame number index.

Contention Subchannel
The number of the subchannel that was used for network entry. The contention subchannels are numbered from 0 to 0xF and this number \( n \) represents the subchannel index \( i \) as specified in Table 248 according to \( i = 2 \times n + 1 \).

8.3.6.3.4 UL-MAP Extended IE format

A UL-MAP IE entry with a UIUC = 15 indicates that the IE carries special information and conforms to the structure shown in Table 288. A station shall ignore an extended IE entry with an extended UIUC value for which the station has no knowledge. In the case of a known extended UIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.
### Table 288—OFDM UL-MAP Extended IE format

</tbody>
</table>

#### 8.3.6.3.5 UL-MAP Power Control IE format

When a power change for the SS is needed, UIUC = 15 is used with extended UIUC set to 0x0 and with 8-bit power control value as shown in Table 289. The power control value is an 8-bit signed integer expressing the change in power level (in 0.25 dB units) that the SS shall apply to correct its current transmission power. If the SS cannot apply the commanded power correction (i.e., SS is already at maximum or minimum power), the SS shall send a RNG-REQ message with Ranging Anomalies parameter.

The CID used in the IE should be the Basic CID of the SS.

### Table 289—OFDM Power Control IE format

</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

#### 8.3.6.3.6 UL-MAP AAS IE format

Within a frame, the switch from non-AAS to AAS-enabled traffic is marked by using the UIUC = 15 with the AAS_IE() to indicate that the subsequent allocation until the end of the frame shall be for AAS traffic. When used, the CID in the UL-MAP_IE() shall be set to the Broadcast CID. Subsequent AAS PHY bursts shall all start with the short preamble. Stations not supporting the AAS functionality shall ignore the portion of the frame marked for AAS traffic. The AAS_IE() shall not be used in AAS private map messages. See Table 290 for the format for OFDM AAS UL IE.
8.3.6.3.7 UL-MAP Physical Modifier IE

The Physical Modifier IE indicates that the subsequent allocations shall utilize a preamble and midambles, which are cyclically delayed in time by $M$ samples, meaning that the waveform transmitted during these training symbols shall be as shown in Equation (38).

$$s(t) = \text{Re}\left\{e^{2j\pi f_c t} \sum_{k=-N_{used}/2}^{k=N_{used}/2} c_k e^{2j\pi k\Delta f(t - T_g - M/F_c)}\right\}$$  

where

$t$ is the time, elapsed since the beginning of the OFDM symbol, with $0 < t < T_g$

Cyclically delaying the preambles and midambles is an optional feature. The PHYMOD UL IE can appear anywhere in the UL-MAP, and it shall remain in effect until another PHYMOD UL IE is encountered or until the end of the UL-MAP.

### Table 291—OFDM UL-MAP Physical Modifier IE format

<table>
<thead>

</tbody>
</table>

Preamble Time Shift

The parameter indicating how many samples of cyclic shift are introduced into the training symbols of the following allocations [$M$ in Equation (38)].

8.3.6.3.8 UL-MAP Dummy IE format

An SS shall be able to decode the UL-MAP Dummy IE (see Table 292). A BS shall not transmit this IE (unless under test).

Table 292—OFDM UL-MAP Dummy IE format

<table>
<thead>
<tr>

</tbody>
</table>

8.3.6.3.9 Fast Ranging IE

A Fast Ranging IE may be placed in the UL-MAP message by a BS to provide a non-contention-based initial ranging opportunity. The Fast Ranging IE shall be placed in the extend UIUC (extension code = 0x03) within a UL-MAP IE. The Fast Ranging IE shall be assigned to the Initial Ranging CID = 0x0000. See Table 293 for the format for OFDM Fast Ranging IE.

Table 293—OFDM Fast Ranging IE format

<table>
<thead>

</tr>
<tr>
<td></td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

BS may assign subchannel indices other than 0b10000, only to the MS that entered the network using the subchannelized network entry (see 8.3.6.3.3).
8.3.6.3.10 UL-MAP Fast Tracking IE

The UL-MAP Fast Tracking IE in an UL-MAP entry is used to provide fast power, time, and frequency indications/corrections to MSs that have transmitted in the previous frame.

The extended UIUC = 15 shall be used for this IE with subcode 0x4.

The CID used in the IE shall be a Broadcast CID. See Table 294 for the format for the UL-MAP Fast Tracking IE.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>UL_Fast_Tracking_IE()</td>

<td>2</td>
<td>Power correction indication: 0b00: no change 0b01: +2 dB 0b10: –1 dB 0b11: –2 dB</td>
</tr>
<tr>
<td>Frequency correction</td>
<td>4</td>
<td>The correction is 0.1% of the subcarrier spacing multiplied by the 4-bit number interpreted as a signed integer (i.e., 0b1000: –8; … 0b0000: 0; … 0b0111: 7)</td>
</tr>
<tr>
<td>Time correction</td>
<td>2</td>
<td>The correction is floor(2 / Fs) multiplied by: 0b00: 0; 0b01: 1; 0b10: –1; 0b11: Not used</td>
</tr>
</tbody>
</table>

The UL Fast tracking IE is an optional field in the UL-MAP. When this IE is sent, it provides an indication about corrections that should be applied by MS’s that have transmitted in the previous UL frame. Each indication byte shall correspond to one unicast allocation-IE that has indicated an UL burst allocation in the previous UL-MAP. The order of the indication bytes shall be the same as the order of the unicast allocation-IE in the UL-MAP.

The response time for corrections following receipt of this IE shall be equal to FPC Time as defined in 10.1. See also 6.3.2.3.34.

8.3.6.4 AAS-FBCK-REQ/RSP message bodies

The AAS-FBCK-REQ/RSP messages are used to request and return measurements that assist beam forming in AAS systems. The format of the AAS-FBCK-REQ message body is shown in Table 315.
Frame Number
The LSBs of the frame number of the burst on which the measurement shall be performed. Shall always point to a future frame.

Start time
Indicates the start time, in units of symbol duration, of the burst on which to perform the measurement. Shall be relative to the start of the frame pointed to by the Frame Number field.

Feedback Request Counter
Increases every time an AAS-FBCK-REQ is sent to the SS. Individual counters shall be maintained for each SS. The value 0 shall not be used.

Frequency measurement resolution
Indicates the frequency measurement points on which to report.

The measurements shall be transmitted in order of increasing frequency index.

The format of the AAS-FBCK-RSP message body is shown in Table 296.

Frame Number
The LSBs of the frame number of the burst on which the measurement was performed. Shall always point to a past frame.

Start time
Indicates start time, in units of symbol duration, of the burst on which the measurement was performed. Shall be relative to the start of the frame pointed to by the “frame number” field.

Feedback Request Counter
Counter from the AAS-FBCK-REQ messages to which this is the response. The value 0 indicates that the response is unsolicited. In this case, the measurement corresponds to the preceding frame.

Frequency Measurement Resolution
Indicates the frequency measurement points reported on.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Number of Frequencies
The number of frequencies to be reported and as implied by the Frequency measurement resolution field.

Re(Frequency_value[i]) and Im(Frequency_value[i])
The real (Re) and imaginary (Im) part of the measured amplitude on the frequency measurement point (low to high frequency) in signed integer fixed point format (±[2 bits].[5 bits]).

RSSI mean value
The mean RSSI as measured on the element pointed to by data measurement type, frame number, and number of frames in the corresponding request. The RSSI is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.

CINR mean value
The mean CINR as measured on the element pointed to by data measurement type, frame number, and number of frames in the corresponding request. The RSSI is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.

8.3.6.5 AAS-BEAM-REQ/RSP message
The AAS Beam Request/Response messages shall be used by a system supporting AAS. This message serves to request channel measurement that will help in adjusting the direction of the adaptive array. This shall be used in conjunction with the AAS preamble. The format for the AAS-BEAM-REQ message is shown in Table 297.

Table 296—OFDM AAS Feedback Response message body

</tr>
</tbody>
</table>
| Measurement Report Type | 2 | 0b00: AAS_BEAM_IE()
Otherwise: Reserved |
| Resolution parameter | 3 | — |
| Beam bit mask | 4 | A bit corresponds to a requested report on the beam |
| Reserved | 4 | Shall be set to zero |
| } | — | — |

**Frame Number**

The 8 LSBs of the frame number in which to perform the measurement.

**Feedback Request Counter**

Every time an AAS-BEAM-REQ is sent to the SS. Individual counters shall be maintained for each SS. The value 0 shall not be used.

**Measurement report type**

The report type to be used.

**Beam Bit Mask**

A bit value of 1 signifies that the corresponding beam is to be reported on.

The format for the AAS-BEAM-RSP message is shown in Table 298.

**Frame Number**

The 8 LSBs of the frame number in which to perform the measurement. If the message is unsolicited corresponds to the previous frame.

**Feedback Request Counter**

Counter from the AAS-BEAM-REQ messages to which this is the response. The value 0 indicates that the response is unsolicited.

**Measurement report type**

The report type to be used.

**Beam Bit Mask**

A bit value of 1 signifies that the corresponding beam is to be reported on.

**RSSI mean value**

The mean RSSI as measured on the element pointed to by data measurement type, frame number, and number of frames in the corresponding request. The RSSI is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.

**CINR mean value**

The mean CINR as measured on the element pointed to by data measurement type, frame number, and number of frames in the corresponding request. The RSSI is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.
The AAS beam pattern report IE shall be used in conjunction with the AAS_BEAM_REQ/RSP messages. This report IE contain the frequency response of the beams transmitted during the AAS_preamble of the corresponding frame. only the beams which corresponds to the Beam Bit mask are reported. The resolution parameter is interpreted as follows:

- resolution parameter == 0b000 => report every 4th subcarrier
- resolution parameter == 0b001 => report every 8th subcarrier
- resolution parameter == 0b010 => report every 16th subcarrier
- resolution parameter == 0b011 => report every 32th subcarrier
- resolution parameter == 0b100 => report every 64th subcarrier

Measurement points shall be on the frequencies corresponding to the negative subcarrier offset indices \(-N_{\text{used}}/2\) plus \(n\) times the indicated subcarrier resolution and corresponding to the positive subcarrier offset indices \(N_{\text{used}}/2\) minus \(n\) times the indicated subcarrier resolution where \(n\) is a positive integer.

The format for the AAS Beam report IE is shown in Table 299.

The real (Re) and imaginary (Im) part of the measured amplitude on the frequency measurement point \(n\) (low to high frequency) from beam \(m\) in signed integer fixed point format ([±][2 bits].[5 bits]).
8.3.6.6 Compressed private maps

The presence of the compressed private DL-MAP format is indicated by the contents of the 2 MSBs of the first data byte. These bits overlay the HT and EC bits of a generic MAC header. When these bits are both set to 1 (an invalid combination for a standard header), the compressed private DL-MAP format is present. A compressed private UL-MAP shall only appear immediately after a compressed private DL-MAP. The presence of a compressed private UL-MAP is indicated by a bit in the compressed private DL-MAP data structure.

A broadcast map, an AAS-DLFP message, a SBCH DL MAP IE, or another private map in a previous frame can point to the compressed private map. Other restrictions of compressed private maps include the following:

- The private map shall be the first message in a PHY burst.
- Private maps shall only be used in the AAS portion of the subframe or within the DL subchannelization zone.
- Private maps are only allowed to use unicast CID values.
- Private maps shall only describe allocations within the AAS portion of the subframe or within the DL subchannelization zone.
- Both UL and DL allocations included in the private map are relative to the next frame.

A modification to the Preamble Time Shift (as defined in 8.3.6.2.7 and 8.3.6.3.7) shall also apply to allocations in subsequent private maps in the private map chain, until modified again or until the end of the private map chain.

The compressed private map is an optional feature that can be negotiated between the SS and BS.

8.3.6.6.1 Compressed private DL-MAP

The compressed private DL-MAP format is presented in Table 300. The message presents the same information as the standard format with one exception. In place of the DL-MAP’s 48-bit Base Station ID parameter, the compressed format provides a subset of the full value. When the compressed format is used, the full 48-bit Base Station ID parameter shall be present in the DCD.
Table 300—Compressed Private DL-MAP message format

<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

**Compressed map indicator**
A value of 0b11 in this field indicates the map message conforms to the compressed format described here. A value of 0b00 in this field indicates the map message conforms to the standard format described in 6.3.2.3.2. Any other value is in error.

**UL-MAP appended**
A value of 1 indicates a compressed UL-MAP (see 8.3.6.6.2) is appended to the current compressed DL-MAP data structure.

**Map message length**
This value specifies the length of the compressed map message(s) beginning with the byte containing the Compressed map indicator and ending with the last byte of the compressed DL-MAP message if the UL-MAP appended bit is not set or the last byte of the UL-MAP compressed message if the UL-MAP appended bit is set. The length includes the computed 8-bit HCS value.

**DCD Count**
Matches the value of the configuration change count of the DCD, which describes the DL burst profiles that apply to this map.
DL IE count
A field that holds the number of CID entries in the following list of DL-MAP IEs.

HCS
A HCS value, as defined in 6.3.2.1.1, is appended to the compressed private DL-MAP.

The HCS is computed across all bytes of the compressed map(s) starting with the byte containing the Compressed map indicator and including appended Compressed Private UL-MAP, if present.

8.3.6.6.2 Compressed Private UL-MAP

The compressed private UL-MAP format is presented in Table 301. The message may only appear after a compressed private DL-MAP message to which it shall be appended. The message presents the same information as the standard format with the exception that the generic MAC header and the UL Channel ID are omitted. The HCS is computed across all bytes of the compressed map(s) starting with the byte containing the Compressed map indicator and including appended UL-MAP, if present.

UCD Count
Matches the value of the Configuration Change Count of the UCD, which describes the UL burst profiles that apply to this map.

Allocation Start Time
Effective start time of the UL allocation defined by the UL-MAP.

8.3.6.7 Reduced private maps

Reduced private maps are based upon the compressed map format; however, they are specifically designed to support a single unicast ID per map. Their use is identical to standard compressed private maps. However, fields have been removed that are not required to support a single ID. The reduced private map shall be pointed to by a broadcast map or private compressed map, which shall define the values of several fields that shall be constant for the duration of the private map chain. The behavior of the compressed map fields that are not present in the reduced private map are described in the following list:
a) **DCD Count.** Optionally included. Only required if DCD count changes.
b) **Base Station ID.** Acquired by the map that initiated the private map chain. Assumed constant for the duration of the private map chain.
c) **CID.** Only required in first map of private map chain.
d) **UCD Count.** Optionally included. Only required in first UL map of private map chain.
e) **Allocation Start Time.** UL start time relative to TTG plus an integer number of symbol times.

### 8.3.6.7.1 Reduced private DL-MAP

The Reduced private DL-MAP format is presented in Table 302. The reduced private DL-MAP message eliminates the fields that are not relevant since the message is targeted to a single CID.

</table>
Map message length
Specifies the length of the reduced map message(s) beginning with the byte containing the Compressed map indicator, including the Reduced Private UL maps if present, and ending with the last byte of the Reduced Private DL-MAP message, the computed 8-bit HCS value.

Compressed map indicator
A value of 0b11 in this field indicates the presence of a compressed map.

UL-MAP appended
A value of 1 indicates a reduced compressed private UL-MAP (see 8.3.6.7.2) is appended to the current private DL-MAP data structure.

CID Included
Specifies if a CID is included. The CID shall be included in the first compressed private MAP if it was pointed to by a DL-MAP IE with a multicast CID.

DCD Count Included
Specifies if a DCD count is included. DCD Count is only required if the DCD count is changed.

PHY Modification Included
Indicates if a preamble modifier is included.

Connection Identifier (CID)
Represents the assignment of the IE to a unicast address.

Preamble Time Shift
The preamble time shift for subsequent DL allocations, as defined in 8.6.3.3.7.

DCD Count
Matches the value of the configuration change count of the DCD, which describes the DL burst profiles that apply to this map.

DIUC
DIUC used for the burst.

Preamble Present
If set, the indicated burst shall start with the short preamble.

Start Time
Indicates the start time, in units of symbol duration, relative to the beginning of the next DL frame (including preamble). The time instants indicated by the Start Time values are the transmission times of the first symbol of the burst including preamble (if present).

Duration
Indicates the duration, in units of OFDM symbols, of the allocation. The duration is inclusive of the preamble contained in the allocation.

HCS
An HCS value, as defined in 6.3.2.1.1, is appended to the end of the reduced map(s) data. The HCS is computed across all bytes of the reduced map(s) starting with the byte containing the Compressed map indicator and including appended Reduced Private UL-MAP(s), if present.

8.3.6.7.2 Reduced private UL-MAP

The Reduced private UL-MAP format is presented in Table 303. The message may only appear after a Reduced private DL-MAP message to which it shall be appended.

UCD Count Included
Indicates if UCD Count is included. This should be included in the first UL map of a private map chain.

Phy Modification Included
Indicates if a preamble modifier is included.

Power Control Included
Indicates if an SS power control byte is included.

Preamble Time Shift
The preamble time shift for subsequent UL allocations, as defined in 8.6.3.3.7.

Power Control
The change in Tx power level that the SS should apply starting on the next frame.

UCD Count
Matches the value of the configuration change count of the UCD, which describes the UL burst profiles that apply to this map.

UIUC
UIUC used for the burst.

Start Time
Indicates the start time of the allocation, in units of symbol duration, referenced to the beginning of the next frame and consists of an integer symbol offset specified here, as well as the addition of the TTG known from DCD messages. If TTG is not present in the DCD (for FDD) it is assume to be zero.

Duration
Indicates the duration, in units of OFDM symbols, of the allocation. The duration is inclusive of the preamble contained in the allocation.

Subchannel Index
See Table 248.

Midamble Repetition Interval
Indicates the preamble repetition interval in OFDM symbols, as defined in 8.3.6.3.

8.3.7 Control mechanisms

8.3.7.1 Synchronization

8.3.7.1.1 Network synchronization

For TDD and FDD realizations, it is recommended (but not required) that all BSs be time synchronized to a common timing signal. In the event of the loss of the network timing signal, BSs may continue to operate and shall automatically resynchronize to the network timing signal when it is recovered. The synchronizing reference shall be a 1 pps timing pulse. A 10 MHz frequency reference may also be used. These signals are typically provided by a GPS receiver.

For both FDD and TDD realizations, frequency references derived from the timing reference may be used to control the frequency accuracy of BSs provided that they meet the frequency accuracy requirements of 8.3.12. This applies during normal operation and during loss of timing reference.

8.3.7.2 Ranging

There are two types of ranging processes—initial ranging (see 6.3.9.5) and periodic ranging (see 6.3.10). Initial ranging and power are performed during two phases of operation; during (re)registration and when synchronization is lost; and secondly, during transmission on a periodic basis. Initial ranging uses the initial ranging contention-based interval, which requires a long preamble. The periodic ranging uses the regular UL burst.
During registration, a new subscriber registers during the random access channel, and, if successful, it is entered into a ranging process under control of the BS. The ranging process is cyclic in nature where default time and power parameters are used to initiate the process followed by cycles where (re)calculated parameters are used in succession until parameters meet acceptance criteria for the new subscriber. These parameters are monitored, measured and stored at the BS, and transmitted to the subscriber unit for use during normal exchange of data. During normal exchange of data, the stored parameters are updated in a periodic manner based on configurable update intervals to ensure that changes in the channel can be accommodated. The update intervals shall vary in a controlled manner on a subscriber unit by subscriber unit basis. Initial ranging transmissions shall use a long preamble and the most robust mandatory burst profile.

Ranging on re-registration follows the same process as new registration.

Regardless of duplexing type, the appropriate duration of the initial ranging slot used for initial system access depends on the intended cell radius.

SSs that compute their $P_{TX\,IR\,max}$ to exceed their maximum power level and SSs that have attempted initial ranging with the maximum power level using RNG-REQ may, if the BS supports subchannelization, attempt initial ranging in an initial ranging slot using the burst format described in this subclause. This signal is referred to as the subchannelized initial ranging signal and is indicated in Figure 213 and Figure 214.

The SS shall transmit the long preamble as defined in 8.3.3.6. This shall be followed by two identical symbols containing a subchannelized preamble, on a single randomly selected subchannel. Note that the long preamble is transmitted on the entire bandwidth while the subchannelized preamble is transmitted on 1/16 of the bandwidth.

The long preamble and the subchannelized preamble shall be transmitted using the same total power. As a result the spectral density of the long preamble shall be lower by a factor of 16 (about 12dB) than the power spectral density of the subchannelized preamble.

The BS need only detect that energy is sent on a single subchannel and may respond by allocating a single subchannel identifying the SS by the Tx opportunity, frame number, and ranging subchannel in which the transmission was received. The allocation is accomplished by sending an UL-MAP IE containing a Subchannelized Network Entry IE (see 8.3.6.3.3) and transmitted using the Initial Ranging CID, as shown in Figure 214. The allocated bandwidth shall be big enough to contain at least one RNG-REQ message.

A SS attempting subchannelized initial ranging shall use its maximum power setting for the initial ranging burst.

**8.3.7.2.1 Initial ranging in AAS systems**

A BS supporting the AAS option may allocate in the UL subframe an AAS alert slot for AAS SSs that have to initially alert the BS of their presence. This period shall be marked as initial ranging (UIUC = 1), but shall be marked by an AAS Initial Ranging CID so that no non-AAS subscriber (or AAS subscriber that can decode the UL-MAP message) uses this interval for initial ranging. Additionally, this period shall be marked using AAS map (see Table 290). The SS shall transmit the long preamble as defined in 8.3.3.6. This shall be followed by a burst carrying the AAS_NW_ENTRY_REQ message (see Table 304). This burst shall use the most robust mandatory coding method (BPSK-1/2).

The BS may respond to the network entry request by transmitting a RNG-RSP message indicating the required changes to the ranging parameters. The SS is identified by specifying the Tx opportunity and the entry code of the AAS_NW_ENTRY_REQ message. When transmitting the response, the BS may use the feedback information embedded in the AAS_NW_ENTRY_REQ to direct the beam to the SS.
The BS may additionally assign subchannelized AAS alert slot for SSs supporting subchannelization. AAS SSs that have attempted initial ranging with the maximum power level using AAS_NW_ENTRY_REQ may attempt initial ranging in the subchannelized AAS alert slot. The SS shall transmit the long preamble as defined in 8.3.3.6. This shall be followed by subchannelized burst carrying the AAS_SBCH_NW_ENTRY_REQ message (see Table 305). This message shall be sent on the subchannel indicated by the UL-MAP information element used to allocate the ranging period.

**Network entry code**
A 4-bit number selected at random.

**Measurement frame index**
The 4 LSBs of the frame number to which the beam measurements refer.

**Re( beam_value[m] ) and Im(beam_value[m] )**
The real (Re) and imaginary (Im) part of the measured amplitude of beam m in signed integer fixed point format ([±][2 bits].[5 bits]). These values are measured on the AAS preamble pointed to by measurement frame index. A single value shall be used for the entire bandwidth.

**RSSI**
The RSSI of the AAS preamble information pointed to by measurement frame index. This value is averaged over the four beams. The RSSI value shall be quantized as in 8.3.9.2.
Network entry code
A 4-bit number selected at random.

Phase offset 1...3
The phase offsets that are required to be performed by the BS, in order to form the beam towards the SS. The phase offsets are estimated using the AAS preamble and are given relative to the first beam.

Measurement frame index
Indicates whether the phase information corresponds to the previous frame or to the one before the previous frame.

RSSI
The RSSI of the AAS preamble information pointed to by measurement frame index. This value is averaged over the four beams. This value shall be quantized in 2 dB increments, ranging from –110 dBm (encoded 0x00) to –48 dBm (encoded 0x1F). Values outside this range shall be assigned the closest extreme value within the scale.

8.3.7.3 Bandwidth requesting
There may be two types of REQ Regions in a frame. These two types are REQ Region-Full and REQ Region-Focused.

</tr>
</tbody>
</table>

In a REQ Region-Full, when subchannelization is not active, each Tx opportunity shall consist of a short preamble and one OFDM symbol using the most robust mandatory coding method (BPSK-1/2). When subchannelization is active, the allocation is partitioned into Transmission Opportunities (TOs) both in
frequency and in time. The width (in subchannels) and length (in OFDM symbols) of each transmission opportunity (TO) is defined in the UCD message defining (see Table 570). The transmission of an SS shall contain a subchannelized preamble corresponding to the TO chosen, followed by data OFDM symbols using the most robust mandatory coding method (BPSK-1/2).

In a REQ Region-Focused, a station shall send a short code over a Tx opportunity that consists of four subcarriers by two OFDM symbols. Each Tx opportunity within a frame shall be indexed by consecutive Tx opportunity indices. The first occurring Tx opportunity shall be indexed 0.

All SS shall be capable of the full contention transmission. Capability of the focused contention transmission is optional. The SS shall follow the backoff procedure as described in 6.3.8.

8.3.7.3.1 Parameter selection

The SS shall examine the UL_MAP message for a future frame and select (in accordance with 6.3.8) a future REQ Region during which to make its request. If Focused Contention Supported = 1 was returned by the BS in SBC-RSP message during SS initialization and if the SS is capable of focused contention, it may choose either a REQ Region-Full or REQ Region-Focused. Otherwise, it shall choose a REQ Region-Full.

If the chosen REQ Region is a REQ Region-Focused, the SS shall also select a contention code from Table 306 and similarly a contention channel from Table 307. The contention channel shall be selected from Table 306 based upon a random selection with equal probability among the group of possible contention channels that are consistent with the allocation, as indicated in Table 307. The indices {–100 to +100} in the body of Table 307 refer to the subcarrier indices as defined in 8.3.2.4. The number of contention codes that can be used by a subchannelized capable SS is denoted by $C_{SE}$. The contention code shall be selected at random with equal probability from the appropriate subset of codes in Table 306 according to the value of $C_{SE}$.

If the BS supports subchannelization, the last $C_{SE}$ contention codes shall only be used by subchannelization-enabled SSs that wish to receive a subchannelized allocation. In response, the BS may provide the requested allocation as a subchannelized allocation; may provide the requested allocation as a full (default) allocation, or may provide no allocation at all. The value of $C_{SE}$ is transmitted in the UCD channel encoding TLV messages. The default value of $C_{SE}$ is 0.

A BS that supports Focused Contention may allocate the Focused Contention region based upon the BSID, thereby reducing the probability of interference from SSs operating in nearby cells operating on the same frequency.

Any Focused Contention region allocation shall be restricted to an even Subchannel Index (meaning that it be no finer than a 1/8 subchannel—see Table 248), providing between 6 and 48 contention channels.

8.3.7.3.2 Full Contention transmission

If the chosen REQ Region is a REQ Region-Full, the SS shall transmit the short preamble as defined in 8.3.3.6, followed by a BR MAC header as defined in 6.3.2.1.2.1.1.

If the Full Contention allocation appears in subchannelized region, the allocation is partitioned into transmission opportunities (TOs) both in frequency and in time. The width (in subchannels) and length (in OFDM symbols) of each transmission opportunity is defined in the UCD message. The transmission of an SS shall contain a subchannelized preamble corresponding to the TO chosen, followed by data OFDM symbols using the most robust mandatory coding method (BPSK-1/2).

8.3.7.3.3 Focused Contention transmission

The REQ Region-Focused bandwidth requesting mechanism consists of two phases. The Phase-1 is that an SS requesting bandwidth sends a signal to the BS in the UL TO of REQ Region Focused identified by UIUC = 3. One REQ Region Focused UL interval with UIUC = 3 shall be four subcarriers by two OFDM symbols. The Phase-1 bandwidth requesting signal transmission is described in this subclause. Following the Phase-1,
the BS may include in its UL-MAP an allocation for the SS using UIUC = 4 and the Focused Contention IE as defined in Table 286. The SS is identified in this Focused Contention IE by the frame number index, Tx opportunity index, contention channel index, and contention code index that the SS used to send the Phase-1 bandwidth requesting signal. The Phase-2 is that the SS requesting bandwidth responds to this UL-MAP allocation with a BR MAC header as defined in 6.3.2.1.2.1.1. The Phase-2 UL interval with UIUC = 4 shall consist of a short preamble and shall have the duration indicated by the relevant field of the UL-MAP_IE() and shall use the most robust mandatory burst profile.

If the chosen REQ Region is a REQ Region-Focused, after choosing its four parameters, the SS shall transmit, during the chosen Tx opportunity in the chosen frame, four subcarriers that comprise the chosen contention channel. The amplitude of all other subcarriers shall be zero.

During both OFDM symbols, the amplitude of each of the four subcarriers shall be boosted somewhat above its normal amplitude, i.e., the amplitude used during a noncontention OFDM symbol, including the current power-control correction. The boost in dB shall equal the value of the Focused Contention Power Boost parameter in the current UCD.

During the first OFDM symbol of the Tx opportunity, the phase of the four subcarriers is not specified.

During the second OFDM symbol of the Tx opportunity, the phases shall depend on the corresponding bit in the chosen contention code, and the phase transmitted during the first OFDM symbol on the same subcarrier. If the code bit is +1, the phase shall be the same as that transmitted during the first OFDM symbol. If the code bit is −1, the phase shall be inverted, 180 degrees with respect to the phase transmitted during the first OFDM symbol.

8.3.7.4 Power control

As with frequency control, a power control algorithm shall be supported for the UL channel with both an initial calibration and periodic adjustment procedure without loss of data. The objective of the power control algorithm is to bring the received power density from a given subscriber to a desired level. The received power density is defined as total power received from a given subscriber divided by the number of active subcarriers. When subchannelization is not employed, the number of active subcarriers is equal for all the subscribers and the power control algorithm shall bring the total received power from a given subscriber to the desired level. The BS shall be capable of providing accurate power measurements of the received burst signal. This value can then be compared against a reference level, and the resulting error can be fed back to the SS in a calibration message coming from the MAC. The power control algorithm shall be designed to support power attenuation due to distance loss or power fluctuations at rates to 30 dB/second with depths of at least 10 dB. The exact algorithm implementation is vendor-specific. The total power control range consists of both a fixed portion and a portion that is automatically controlled by feedback. The power control algorithm shall take into account the interaction of the RF power amplifier with different burst profiles. For example, when changing from one burst profile to another, margins should be maintained to prevent saturation of the amplifier and to prevent violation of emissions masks.

8.3.7.4.1 Closed-loop power control mode

When subchannelization is employed in the UL, the SS shall maintain the same transmitted power density unless the maximum power level is reached. In other words, when the number of active subchannels allocated to a user is reduced, the total transmitted power shall be reduced proportionally by the SS, without additional power control messages. When the number of subchannels is increased the total transmitted power shall also be increased proportionally. However, the transmitted power level shall not exceed the maximum levels dictated by signal integrity considerations and regulatory requirements. SSs shall report the maximum available power and the current average transmitted power.
When subchannelization is employed in the DL, the BS may vary the power of individual subchannelized allocations to improve the link budget to particular MS’s. The transmitted power level shall not exceed the maximum levels dictated by signal integrity considerations and regulatory requirements. Within a given DL subchannelized allocation the spectral flatness requirement as specified in 8.3.10.1.1 applies to all the energized subcarriers.

Explicitly, let PSDref be the reference level of power spectrum density of the SS. This can only be changed by power control messages. The Tx power of the SS is defined as current tx power = min((number used subchannels) × PSDref, maximum available power). Thus, in the case of saturation, the reference level of power spectrum density shall not be changed.

SSs shall report the maximum available power and the current transmitted power. These parameters may be used by the BS for optimal assignment of coding schemes and modulations and also for optimal allocation of subchannels. The algorithm is vendor-specific. These parameters are reported in the SBC-REQ message. The current transmitted power shall also be reported in the REP-RSP message if the relevant flag in the REP-REQ message has been set.

The current transmitted power is the power of the burst that carries the message. The maximum available power is reported for BPSK, QPSK QAM16, and QAM64 constellations. The current transmitted power and the maximum power parameters are reported in dBm. The parameters are quantized in 0.5 dBm steps ranging from –64 dBm (encoded 0x00) to 63.5 dBm (encoded 0xFF). Values outside this range shall be assigned the closest extreme. SSs that do not support QAM64 shall report the value of 0x00 in the maximum QAM64 power field.

8.3.7.4.2 Open loop power control mode (optional)

When the open-loop power control is supported and the UL power control mode is changed to open-loop power control by PMC_RSP, the power per a subcarrier shall be maintained for the UL transmission as follows.

This open-loop power control shall be applied for all the UL bursts.

\[
P_{EIRP}(dBm) = PL + CNR + R + (N + I) + 10\log_{10}(BW_{sch}) + Offset_{SS_{perSS}} + Offset_{BS_{perSS}}
\]

where

- \(P_{EIRP}\) is the Tx effective isotropic radiated power (EIRP) level, expressed in dBm, per subcarrier for the current transmission. It includes the MS Tx antenna gain and its related coupling losses.
- \(PL\) is the estimated average current UL path loss.
- \(CNR\) is the normalized Carrier to Noise Ratio (per subcarrier) for the given modulation, FEC and the related Convolutional Coding scheme used for the current transmission as presented in Table 308. The normalized Carrier to Noise Ratio can be modified by UCD (Normalized C/N override).
- \(R\) is the number of repetitive sequences used by the receiving circuitry employed to determine the path losses.
- \(BW_{sch}\) is the bandwidth occupied by an OFDM subcarrier, expressed in Hz.
- \(N+I\) is the estimated normalized average power level (dBm) of the noise and interference per subcarrier at the Rx antenna port of the receiving side (BS), for \(BW = 1\) Hz. It does not include the equivalent gain of the Rx antenna and its related coupling losses.
- \(OffsetMS_{UL}\) represents the correction term for SS-specific power offset. Practically it amounts to the desired Fade Margin for the respective UL link. It is controlled by the MS and initially is set to zero.
OffsetBS_UL represents the MS-specific power offset, controlled by the BS through the power control messages. When OffsetBS_UL is set through the PMC_RSP message, it shall include the equivalent BS Rx antenna gain, including its related coupling losses, measured at the antenna port of the equipment.

The normalized CNR is calculated based on noise figure = 7 dB and modulation implementation losses = 5 dB.

The estimated average current UL propagation loss, PLUL, shall be calculated based on the total power received on the active subcarriers of the frame preamble, referenced to the BS_EIRP parameter sent by the BS.

Table 308 returns the default normalized CNR values per modulation. The operating parameters BS_EIRP and NI are signaled by a DCD message (see Table 575 in 11.4.1).

Additionally, the BS controls the Offset_BSperSS using PMC_RSP message (6.3.2.3.53) to override the Offset_BSperSS value or using RNG-RSP (6.3.2.3.6), FPC message (6.3.2.3.34), Power Control IE (8.3.6.3.5) to adjust the Offset_BSperSS value. The accumulated power control value shall be used for Offset_BSperSS.

The Offset_BSperSS can be updated using relative or fixed form (as a function of the relevant adjustment commands used). Fixed form is used when the parameter is obtained from a PMC_RSP message. In this case, the MS should replace the old Offset_SSperSS value by the new Offset_SSperSS sent by the BS. With all other messages mentioned in the previous paragraph, relative form is used. In this case, MS should increase and decrease the Offset_SSperSS according to the offset value sent by BS.

The actual power setting shall be quantized to the nearest implementable value, subject to the specification. For each transmission, the SS shall limit the power, as required to satisfy the spectral masks and EVM requirements.

The UL open-loop power control may be passive or active.

In passive UL open-loop power control, the MS shall set Offset_SSperSS to zero and modify the TX power value using Equation (39).

In active UL open-loop power control, the SS may adjust Offset_SSperSS value within a range as shown in Equation (40).

\[ \text{Offset\_Bound\_lower} \leq \text{Offset\_perSS} \leq \text{Offset\_Bound\_upper} \]  

(40)

where

- \( \text{Offset\_Bound\_upper} \) is the upper bound of \( \text{Offset\_SS\_perSS} \)
- \( \text{Offset\_Bound\_lower} \) is the lower bound of \( \text{Offset\_SS\_perSS} \)

### 8.3.8 Tx diversity: space-time coding (STC) (optional)

STC, in some cases also termed space-time transmit diversity (STTD), may be used on the DL to provide higher order (space) Tx diversity (see Alamouti [B1]).

There are two Tx antennas on the BS side and one reception antenna on the SS side. This scheme requires Multiple Input Single Output channel estimation. Decoding is very similar to maximum ratio combining.

Figure 215 shows STC insertion into the OFDM chain. Each Tx antenna has its own OFDM chain, but they have the same Local Oscillator for synchronization purposes.

Both antennas transmit in the same time two different OFDM data symbols. Transmission is performed twice to decode and to get second order diversity. Time domain (Space-Time) repetition is used.

#### 8.3.8.1 Multiple input single output channel estimation and synchronization

Both antennas transmit in the same time, and they share the same Local Oscillator. Thus, the received signal has exactly the same auto-correlation properties as for a single antenna. So, time and frequency coarse and fine estimation can be performed in the same way as for a single antenna. The scheme requires MISO channel estimation, which is provisioned by inserting an STC preamble, transmitted from both antennas, using the STC IE (see 8.3.6.2.5 and 8.3.3.6).

#### 8.3.8.2 STC encoding

The basic scheme (see Alamouti [B1]) transmits two complex symbols \( s_0 \) and \( s_1 \), using the multiple input single output channel (two Tx, one Rx) twice with channel vector values \( h_0 \) (for antenna 0) and \( h_1 \) (for antenna 1).
First channel use: Antenna 0 transmits \( s_0 \), antenna 1 transmits \( s_1 \).

Second channel use: Antenna 0 transmits \( -s_1^* \), antenna 1 transmits \( s_0^* \).

Receiver gets \( r_0 \) (first channel use) and \( r_1 \) (second channel use) and computes \( s_0 \) and \( s_1 \) estimates:

\[
\hat{s}_0 = h_0^* \cdot r_0 + h_1 \cdot r_1^* \quad (41)
\]

\[
\hat{s}_1 = h_1^* \cdot r_0 - h_0 \cdot r_1^* \quad (42)
\]

These estimates benefit from second order diversity as in the 1Tx-2Rx Maximum Ratio Combining scheme. OFDM symbols are taken by pairs. The precoding operation, and consequentially the receive decoding [as described in Equation (41) and Equation (42)], is applied independently to same-numbered subcarriers in two consecutive OFDM data symbols. Note that the two OFDM symbols may belong to different PHY bursts and even use different constellations. An individual PHY burst may contain any integer number of symbols. The aggregate duration of all PHY bursts following the last STC preamble or between any two STC preambles shall be a multiple of 2.

On a given pilot subcarrier, the same pilot symbol is used for the STC block. If the STC block consists of OFDM symbol \( k \) and \( k+1 \) and \( p_s \) is the pilot symbol for pilot subcarrier \( s \) as derived for OFDM symbol \( k \) from 8.3.3.4.2, then the modulation on pilot subcarrier \( s \) during OFDM symbol \( k \) shall be \( p_s \) on both antenna 0 and 1. During OFDM symbol \( k+1 \), it shall be \( -p_s \) on antenna 0 and \( p_s \) on antenna 1.

Figure 216 shows the STC scheme (note that only pilot subcarrier –88 is depicted).

**Figure 216—STC usage with OFDM**

### 8.3.8.3 STC decoding

The receiver waits for two symbols, and combines them on a subcarrier basis according to Equation (41) and Equation (42) in 8.3.8.2.
8.3.9 Channel quality measurements

8.3.9.1 Introduction

RSSI and CINR signal quality measurements and associated statistics can aid in such processes as BS selection/assignment and burst adaptive profile selection. As channel behavior is time-variant, both mean and standard deviation are defined. Implementation of the RSSI and CINR statistics and their reports is mandatory.

The process by which RSSI measurements are taken does not necessarily require receiver demodulation lock; for this reason, RSSI measurements offer reasonably reliable channel strength assessments even at low signal levels. On the other hand, although CINR measurements require receiver lock, they provide information on the actual operating condition of the receiver, including interference and noise levels, and signal strength.

8.3.9.2 RSSI mean and standard deviation

When collection of RSSI measurements is mandated by the BS, an SS shall obtain an RSSI measurement from the OFDM DL long preambles. From a succession of RSSI measurements, the SS shall derive and update estimates of the mean and the standard deviation of the RSSI, and report them via REP-RSP messages.

Mean and standard deviation statistics shall be reported in units of dBm. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from –40 dBm (encoded 0x53) to –123 dBm (encoded 0x00). Values outside this range shall be assigned the closest extreme value within the scale.

The method used to estimate a single RSSI measurement is left to individual implementation, but the relative accuracy of a single signal strength measurement, taken from a single message, shall be ± 2 dB, with an absolute accuracy of ± 4 dB. The specified accuracy shall apply to the range of RSSI values starting from 6 dB below the sensitivity level of the most robust mode or –123 dBm ( whichever is higher) up to –40 dBm. In addition, the range over which these single-message measurements are measured should extend 3 dB on each side beyond the –40 dBm to –123 dBm limits for the final averaged statistics that are reported.

One possible method to estimate the RSSI of a signal of interest at the antenna connector is given by Equation (43).

\[
RSSI = 10 \frac{G_{rt}}{10} \times 10^{4} \times \frac{1}{(2.2^{B})R} \times \left( \frac{\sum_{n=0}^{N-1} [Y_{I,Q}(k, n)]}{N} \right)^{2} \text{ mW}
\]

where

- \( B \) is the ADC precision, number of bits of ADC
- \( R \) is the ADC input resistance [Ohm]
- \( V_{c} \) is the ADC input clip level [Volts]
- \( G_{rt} \) is the analog gain from antenna connector to ADC input
- \( Y_{I,Q}(k, n) \) is the \( n^{th} \) sample at the ADC output of I or Q-branch within signal \( k \)
- \( N \) is the number of samples

The (linear) mean RSSI statistics (in mW), derived from a multiplicity of single messages, shall be updated using Equation (44).
\[
\hat{\mu}_{\text{RSSI}}[k] = \begin{cases} 
R[0] & k = 0 \\
(1 - \alpha_{\text{avg}})\hat{\mu}_{\text{RSSI}}[k-1] + \alpha_{\text{avg}}R[k] & k > 0 
\end{cases} \text{ mW} (44)
\]

where \(k\) is the time index for the message (with the initial message being indexed by \(k = 0\), the next message by \(k = 1\), etc.), \(R[k]\) is the RSSI in mW measured during message \(k\), and \(\alpha_{\text{avg}}\) is an averaging parameter specified by the BS. The mean estimate in dBm shall then be derived from Equation (45).

\[
\hat{\mu}_{\text{RSSI dBm}}[k] = 10\log(\hat{\mu}_{\text{RSSI}}[k]) \text{ dBm} \quad (45)
\]

To solve for the standard deviation in dB, the expectation-squared statistic shall be updated using Equation (46),

\[
\hat{x}^2_{\text{RSSI}}[k] = \begin{cases} 
[R[0]]^2 & k = 0 \\
(1 - \alpha_{\text{avg}})\hat{x}^2_{\text{RSSI}}[k-1] + \alpha_{\text{avg}}R[k]^2 & k > 0 
\end{cases} \text{ (mW)}^2 (46)
\]

and the result applied to Equation (47).

\[
\hat{\sigma}_{\text{RSSI dBm}} = 10\log\left(\frac{\hat{x}^2_{\text{RSSI}}[k] - (\hat{\mu}_{\text{RSSI}}[k])^2}{\hat{\mu}_{\text{RSSI}}[k]^2}\right) \text{ dBm} \quad (47)
\]

### 8.3.9.3 CINR mean and standard deviation

When CINR measurements are mandated by the BS, an SS shall obtain a CINR measurement (implementation-specific). From a succession of these measurements, the SS shall derive and update estimates of the mean and the standard deviation of the CINR, and report them via REP-RSP messages.

Mean and standard deviation statistics for CINR shall be reported in units of dB. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from a minimum of –10 dB (encoded 0x00) to a maximum of 53 dB (encoded 0x3F). Values outside this range shall be assigned the closest extreme value within the scale.

The method used to estimate the CINR of a single message is left to individual implementation, but the relative and absolute accuracy of a CINR measurement derived from a single message shall be ± 1 dB and ± 2 dB, respectively. The specified accuracy shall apply to the range of CINR values starting from the SNR of the most robust rate to 3 dB above the SNR of the least robust rate. See Table 312. In addition, the range over which these single-packet measurements are measured should extend 3 dB on each side beyond the –10 dB to 53 dB limits for the final reported, averaged statistics.

One possible method to estimate the CINR of a single message is to compute the ratio of the sum of signal power and the sum of residual error for each data sample, using Equation (48).

\[
\text{CINR}[k] = \frac{\sum_{n=0}^{N-1} |r[k,n]|^2}{\sum_{n=0}^{N-1} |r[k,n] - s[k,n]|^2} \quad (48)
\]

where \(r[k,n]\) received sample \(n\) within message \(k\); \(s[k,n]\) the corresponding detected or pilot sample (with channel state weighting) corresponding to received symbol \(n\).
The mean CINR statistic (in dB) shall be derived from a multiplicity of single messages using Equation (49).

\[
\tilde{\mu}_{\text{CINR,db}}[k] = 10\log(\mu_{\text{CINR}}[k])
\]  

(49)

where

\[
\hat{\mu}_{\text{CINR}}[k] = \begin{cases} 
\text{CINR}[0] & k = 0 \\
(1 - \alpha_{\text{avg}})\hat{\mu}_{\text{CINR}}[k - 1] + \alpha_{\text{avg}} \text{CINR}[k] & k > 0
\end{cases}
\]  

(50)

\( k \) is the time index for the message (with the initial message being indexed by \( k = 0 \), the next message by \( k = 1 \), etc.)

CINR[\( k \)] is a linear measurement of CINR (derived by any mechanism that delivers the prescribed accuracy) for message \( k \)

\( \alpha_{\text{avg}} \) is an averaging parameter specified by the BS

To solve for the standard deviation, the expectation-squared statistic shall be updated using Equation (51),

\[
\hat{x}_{\text{CINR}}^2[k] = \begin{cases} 
\text{CINR}[0]^2 & k = 0 \\
(1 - \alpha_{\text{avg}})\hat{x}_{\text{CINR}}^2[k - 1] + \alpha_{\text{avg}} \text{CINR}[k]^2 & k > 0
\end{cases}
\]  

(51)

and the result applied to Equation (52).

\[
\hat{\sigma}_{\text{CINR,db}} = 10\log([\hat{x}_{\text{CINR}}^2[k] - (\hat{\mu}_{\text{CINR}}[k])]^2) \text{ dB}
\]  

(52)

8.3.10 Transmitter requirements

All requirements on the transmitter apply to the RF output connector of the equipment. For equipment with integral antenna only, a reference antenna with 0 dBi gain shall be assumed.

8.3.10.1 Tx power level control

For an SS not supporting subchannelization, the transmitter shall support a monotonic power level control of 30 dB minimum. For an SS supporting subchannelization, the transmitter shall support a monotonic power level control of 50 dB minimum. The minimum step size shall be no more than 1 dB. The relative accuracy of the power control mechanism is \( \pm 1.5 \) dB for step sizes not exceeding 15 dB, \( \pm 3 \) dB for step sizes from 15 dB to 30 dB, and \( \pm 5 \) dB for step sizes greater than 30 dB. For a BS, the transmitter shall support a monotonic power level control of 10 dB minimum.

8.3.10.2 Transmitter spectral flatness

The average energy of the constellations in each of the \( n \) spectral lines shall deviate no more than indicated in Table 309. The absolute difference between adjacent subcarriers shall not exceed 0.4 dB.

The power transmitted at spectral line 0 shall not exceed –15 dB relative to total transmitted power.

This data shall be taken from the channel estimation step.
8.3.10.3 Transmitter constellation error and test method

To ensure that the receiver SNR does not degrade more than 0.5 dB due to the transmitter SNR, the relative constellation RMS error, averaged over subcarriers, OFDM frames, and packets, shall not exceed a burst profile dependent value according to Table 310.

Table 309—OFDM Spectral flatness

</tbody>
</table>

The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps, or an equivalent procedure (IEEE Std 802.11-2007, Clause 17 [B29]):

a) Start of frame shall be detected.
b) Transition from short sequences to channel estimation sequences shall be detected, and fine timing (with one sample resolution) shall be established.
c) Coarse and fine frequency offsets shall be estimated.
d) The packet shall be de-rotated according to estimated frequency offset.
e) The complex channel response coefficients shall be estimated for each of the subcarriers.
f) For each of the data OFDM symbols, transform the symbol into subcarrier received values, estimate the phase from the pilot subcarriers, de-rotate the subcarrier values according to estimated phase, and divide each subcarrier value with a complex estimated channel response coefficient. In the case of subchannelization transmission, the estimated channel coefficient of the nearest allocated subcarrier shall be used for those subcarriers not part of the allocated subchannels.
g) For each data-carrying subcarrier, find the closest constellation point and compute the Euclidean distance from it. In the case of subchannelization transmission, for data-carrying subcarriers not part of the allocated subchannels, the Euclidean distance shall be computed relative to 0+0j.
h) Compute the RMS average of all errors in a packet. It is given by Equation (53).

\[
\text{Error}_{\text{RMS}} = \frac{1}{N_f} \sum_{i=1}^{L_p} \sum_{j=1}^{N_f \cdot 2} \sum_{k=0}^{N_{\text{used}}/2} \left\{ (I(i,j,k) - I_0(i,j,k))^2 + (Q(i,j,k) - Q_0(i,j,k))^2 \right\}
\]

(53)

where

- \(L_p\) is the length of the packet
- \(N_f\) is the number of frames for the measurement
- \((I_0(i,j,k), Q_0(i,j,k))\) denotes the ideal symbol point of the \(i^{th}\) frame, \(j^{th}\) OFDM symbol of the frame, \(k^{th}\) subcarrier of the OFDM symbol in the complex plane
- \((I(i,j,k), Q(i,j,k))\) denotes the observed point of the \(i^{th}\) frame, \(j^{th}\) OFDM symbol of the frame, \(k^{th}\) subcarrier of the OFDM symbol in the complex plane

8.3.10.4 Transmitter channel bandwidth and RF carrier frequencies

For licensed bands, channel bandwidths allowed shall be limited to the regulatory provisioned bandwidth divided by any power of 2, rounded down to the nearest multiple of 250 kHz, resulting in a channel bandwidth no less than 1.25 MHz.

If the resulting channel bandwidth is an odd multiple of 250 kHz, then for any band for which support is claimed, the RF carrier shall only be tunable to every odd multiple of 125 kHz within that band. If the resulting channel bandwidth is an even multiple of 250 kHz, then for any band for which support is claimed, the RF carrier shall only be tunable to every even multiple of 125 kHz within that band. For FDD systems, support shall be claimed separately for UL and DL.

For example, if the regulatory provisioned bandwidth is 14 MHz between 3400 and 3414 MHz, then the allowed channelled bandwidths are those shown in Table 311.

<table>
<thead>
<tr>
<th>Channelization (MHz)</th>

</tr>
</tbody>
</table>

8.3.11 Receiver requirements

All requirements on the receiver apply to the RF input connector of the equipment. For equipment with integral antenna only, a reference antenna with 0 dBi gain shall be assumed.
8.3.11.1 Receiver sensitivity

The BER measured after FEC shall be less than $10^{-6}$ at the power levels given by Equation (54) for standard message and test conditions. If the implemented bandwidth is not listed, then the values for the nearest smaller listed bandwidth shall apply. The minimum input levels are measured as follows:

- Using the defined standardized message packet formats
- Using an AWGN channel

The receiver minimum input level sensitivity ($R_{SS}$) shall be (assuming 5 dB implementation margin and an 8 dB noise figure) as shown in Equation (54).

$$
R_{SS} = -10 \log_{10} \left( \frac{SNR \cdot N_{used} \cdot N_{subchannels}}{16} \right) + 10 \cdot \log_{10} \left( \frac{NFFT}{N_{FFT}} \right)
$$

where

$SNR_{Rx}$ is the receiver SNR (dB) per Table 312
$F_S$ is the sampling frequency (MHz) as defined in 8.3.2.2
$N_{subchannels}$ is the number of allocated subchannels (default 16 if no subchannelization is used)

Note that these SNR values are derived in an AWGN environment and assume that Reed-Solomon convolutional coding (RS-CC) is used.

Test messages for measuring Receiver Sensitivity shall be based on a continuous stream of MAC PDUs, each with a payload containing an $R$ times repeated sequence $S_{modulation}$. For each modulation, a different sequence applies:

$S_{BPSK} = [0xE4,0xB1]$
$S_{QPSK} = [0xE4, 0xB1, 0xE1, 0xB4]$
$S_{16-QAM} = [0xA8, 0x20, 0xB9, 0x31, 0xEC, 0x64, 0xFD, 0x75]$
$S_{64-QAM} = [0xB6, 0x93, 0x49, 0x2B, 0x83, 0x08, 0x96, 0x11, 0x41, 0x92, 0x01, 0x00, 0xBA, 0xA3, 0x8A, 0x9A, 0xB7, 0x01, 0x75, 0x15, 0x51, 0xD3, 0x05, 0x10, 0xDB, 0x25, 0x92, 0xF7, 0x97, 0x59, 0xF3, 0x87, 0x18, 0xBE, 0xB3, 0xCB, 0x9E, 0x31, 0xC3, 0xDF, 0x35, 0xD3, 0xFB, 0xA7, 0x9A, 0xFF, 0xB7, 0xDB] \quad (55)$
For each mandatory test message, the \((R, S_{\text{modulation}})\) tuples that shall apply are as follows:

- Short length test message payload (288 data bytes): \((144, S_{8PSK}), (72, S_{QPSK}), (36, S_{16-QAM}), (6, S_{64-QAM})\)
- Mid-length test message payload (864 data bytes): \((432, S_{8PSK}), (216, S_{QPSK}), (108, S_{16-QAM}), (18, S_{64-QAM})\)
- Long length test message payload (1488 data bytes): \((744, S_{8PSK}), (372, S_{QPSK}), (186, S_{16-QAM}), (31, S_{64-QAM})\)

The test condition requirements are: ambient room temperature, shielded room, conducted measurement at the RF port if available, radiated measurement in a calibrated test environment if the antenna is integrated, and RS FEC is enabled. The test shall be repeated for each test message length and for each \((R, S_{\text{modulation}})\) tuple as identified above, using the mandatory FEC scheme. The results shall meet or exceed the sensitivity requirements set out in Equation (54).

### 8.3.11.2 Receiver adjacent and alternate channel rejection

The receiver adjacent and alternate channel rejection shall be met over the required dynamic range of the receiver, from 3 dB above the reference sensitivity level specified in 8.3.11.1 to the maximum input signal level as specified in 8.3.11.3.

The adjacent channel rejection and alternate channel rejection shall be measured at minimum sensitivity by setting the desired signal’s strength 3 dB above the rate dependent receiver sensitivity [see Equation (54)] and raising the power level of the interfering signal until the error rate specified in 8.3.11.1 is obtained. The adjacent channel rejection and alternate channel rejection shall also be measured at maximum input level by setting the interfering channel signal strength to the receiver maximum signal level as specified in 8.3.11.3 and decreasing the power level of the desired signal until the specified error rate is obtained. In both cases, the power difference between the desired signal and the interfering channel is the corresponding C/I ratio. The interfering signal shall be a conforming OFDM signal, unsynchronized with the signal in the channel under test. The requirement shall be met on both sides of the desired signal channel. For nonadjacent channel testing, the test method is identical except the interfering channel shall be any channel other than the adjacent channel or the co-channel. For the PHY to be compliant, the minimum rejection shall exceed the values shown in Table 313.

### Table 313—Adjacent and nonadjacent channel rejection

</tbody>
</table>

### 8.3.11.3 Receiver maximum input signal

The receiver shall be capable of decoding a maximum on-channel signal of –30 dBm.

### 8.3.11.4 Receiver maximum tolerable signal

The receiver shall tolerate a maximum signal of 0 dBm without damage.
8.3.11.5 Receiver image rejection

The receiver shall provide a minimum image rejection of 50 dB. The image rejection requirement shall be inclusive of all image terms originating at the receiver RF and subsequent intermediate frequencies.

8.3.12 Frequency and timing requirements

At the BS, the transmitted center frequency, receive center frequency and the symbol clock frequency shall be derived from the same reference oscillator. At the BS the reference frequency tolerance shall be better than $\pm 8 \times 10^{-6}$ in licensed bands up to 10 years from the date of equipment manufacture.

At the SS, both the transmitted center frequency and the sampling clock frequency shall be synchronized and locked to the BS with a tolerance of maximum 2% of the subcarrier spacing for the transmitted center frequency and 5 ppm for the sampling clock frequency. In the case of subchannelization, the tolerance for transmitted center frequency shall be maximum 1% of the subcarrier spacing.

During the synchronization period, the SS shall acquire frequency synchronization within the specified tolerance before attempting any UL transmission. During normal operation, the SS shall track the frequency changes and shall defer any transmission if synchronization is lost.

All SSs shall acquire and adjust their timing so that all UL OFDM symbols arrive time coincident at the BS to a accuracy of $\pm 50\%$ of the minimum guard-interval or better.

8.4 WirelessMAN-OFDMA PHY

8.4.1 Introduction

The WirelessMAN-OFDMA PHY (Sari and Karam [B40]), based on OFDM modulation, is designed for NLOS operation in the frequency bands below 11 GHz per 1.3.4. For licensed bands, channel bandwidths allowed shall be limited to the regulatory provisioned bandwidth divided by any power of 2 no less than 1.0 MHz.

The OFDMA PHY mode based on at least one of the FFT sizes 2048 (backward compatible to IEEE Std 802.16-2004), 1024, 512, and 128 shall be supported. This facilitates support of the various channel bandwidths.

The MS may implement a scanning and search mechanism to detect the DL signal when performing initial network entry, and this may include dynamic detection of the FFT size and the channel bandwidth employed by the BS.

8.4.2 OFDMA symbol description, symbol parameters and transmitted signal

8.4.2.1 Time domain description

Inverse-Fourier-transforming creates the OFDMA waveform; this time duration is referred to as the useful symbol time $T_b$. A copy of the last $T_g$ of the useful symbol period, termed CP, is used to collect multipath, while maintaining the orthogonality of the tones. Figure 217 illustrates this structure.

The transmitter energy increases with the length of the guard time while the receiver energy remains the same (the cyclic extension is discarded), so there is a $10 \log (1 - T_g/(T_b + T_g))/\log (10)$ dB loss in $E_b/N_0$. Using a cyclic extension, the samples required for performing the FFT at the receiver can be taken anywhere over the length of the extended symbol. This provides multipath immunity as well as a tolerance for symbol time synchronization errors.
On initialization, an SS should search all possible values of CP until it finds the CP being used by the BS. The SS shall use the same CP on the UL. Once a specific CP duration has been selected by the BS for operation on the DL, it should not be changed. Changing the CP would force all the SSs to resynchronize to the BS.

8.4.2.2 Frequency domain description

The frequency domain description includes the basic structure of an OFDMA symbol.

An OFDMA symbol is made up of subcarriers, the number of which determines the FFT size used. There are several subcarrier types, as follows:

- Data subcarriers: for data transmission
- Pilot subcarriers: for various estimation purposes
- Null carrier: no transmission at all, for guard bands and DC carrier

The purpose of the guard bands is to enable the signal to naturally decay and create the FFT “brick wall” shaping.

In the OFDMA mode, the active subcarriers are divided into subsets of subcarriers, each subset is termed a subchannel. In the DL, a subchannel may be intended for different (groups of) receivers; in the UL, a transmitter may be assigned one or more subchannels, several transmitters may transmit simultaneously. The subcarriers forming one subchannel may, but need not be adjacent. The concept is shown in Figure 218.

The symbol is divided into logical subchannels to support scalability, multiple access, and advanced antenna array processing capabilities.

---

Figure 217—OFDMA symbol time structure

Figure 218—OFDMA frequency description (3 channel schematic example)
8.4.2.3 Primitive parameters

The following four primitive parameters characterize the OFDMA symbol:

— **BW**: The nominal channel bandwidth.

— **N<sub>used</sub>**: Number of used subcarriers (which includes the DC subcarrier).

— **n**: Sampling factor. This parameter, in conjunction with **BW** and **N<sub>used</sub>** determines the subcarrier spacing and the useful symbol time. This value is set as follows: for channel bandwidths that are a multiple of 1.75 MHz, then **n** = 8/7; else, for channel bandwidths that are a multiple of any of 1.25, 1.5, 2, or 2.75 MHz, then **n** = 28/25; else, for channel bandwidths not otherwise specified, then **n** = 8/7.

— **G**: This is the ratio of CP time to “useful” time. The following values shall be supported: 1/32, 1/16, 1/8, and 1/4.

8.4.2.4 Derived parameters

The following parameters are defined in terms of the primitive parameters of 8.4.2.3:

— **N<sub>FFT</sub>**: Smallest power of two greater than **N<sub>used</sub>**

— Sampling frequency: **f<sub>s</sub>** = \( \text{floor}(n \cdot \text{BW}/8000) \times 8000 \)

— Subcarrier spacing: \( \Delta f = f_s / N_{FFT} \)

— Useful symbol time: \( T_b = 1/\Delta f \)

— CP time: \( T_g = G \cdot T_b \)

— OFDMA symbol time: \( T_s = T_b + T_g \)

— Sampling time: \( T_b / N_{FFT} \)

8.4.2.5 Transmitted signal

Equation (56) specifies the transmitted signal voltage to the antenna, as a function of time, during any OFDMA symbol.

\[
s(t) = \text{Re} \left( j^{2 \pi f_c t} e^{(N_{used} - 1)/2} \sum_{k=-\frac{(N_{used} - 1)}{2}}^{\frac{(N_{used} - 1)}{2}} c_k e^{j2\pi k\Delta f(t - T_g)} \right)
\]

where

- **t** is the time, elapsed since the beginning of the subject OFDMA symbol, with \( 0 < t < T_s \)

- **c<sub>k</sub>** is a complex number; the data to be transmitted on the subcarrier whose frequency offset index is \( k \), during the subject OFDMA symbol. It specifies a point in a QAM constellation.

- **T<sub>g</sub>** is the guard time

- **T<sub>s</sub>** is the OFDMA symbol duration, including guard time

- **\( \Delta f \)** is the subcarrier frequency spacing
8.4.3 OFDMA basic terms definition

8.4.3.1 Slot and data region

A slot in the OFDMA PHY requires both a time and subchannel dimension for completeness (subchannels are defined in 8.4.6.) and is the minimum possible data allocation unit.

The definition of an OFDMA slot depends on the OFDMA symbol structure, which varies for UL and DL, for FUSC and PUSC, and for the distributed subcarrier permutations and the adjacent subcarrier permutation.

- For DL FUSC (defined in 8.4.6.1.2.2) and DL optional FUSC (defined in 8.4.6.1.2.3), one slot is one subchannel by one OFDMA symbol.
- For DL PUSC (defined in 8.4.6.1.2.1), one slot is one subchannel by two OFDMA symbols.
- For UL PUSC (defined in 8.4.6.2.1 and 8.4.6.2.5) and for DL TUSC1 and TUSC2 (defined in 8.4.6.1.2.4 and 8.4.6.1.2.5), one slot is one subchannel by three OFDMA symbols.
- For the adjacent subcarrier permutation (defined in 8.4.6.3), one slot is one subchannel by two, three, or six OFDMA symbols.

In OFDMA, a data region is a two-dimensional allocation of a group of contiguous subchannels, in a group of contiguous OFDMA symbols. All the allocations refer to logical subchannels. A two-dimensional allocation may be visualized as a rectangle, such as the $4 \times 3$ rectangle shown in Figure 219.

![Figure 219—Example of a data region that defines an OFDMA allocation](image)

8.4.3.2 Segment

A segment is a subdivision of the set of available OFDMA subchannels (that may include all available subchannels). One segment is used for deploying a single instance of the MAC.

8.4.3.3 Permutation zone

Permutation zone is a number of contiguous OFDMA symbols, in the DL or the UL, that use the same permutation formula. The DL subframe or the UL subframe may contain more than one permutation zone.

8.4.3.4 OFDMA data mapping

MAC data shall be processed as described in 8.4.9 and shall be mapped to an OFDMA data region (see 8.4.3.1) for DL and UL using the algorithms defined below.

DL:

a) Segment the data into blocks sized to fit into one OFDMA slot.
b) Each slot shall span one subchannels in the subchannel axis and one or more OFDMA symbols in the time axis, as per the slot definition in 8.4.3.1 (see Figure 220 for an example). Map the slots so that the lowest numbered slot occupies the lowest numbered subchannel in the lowest numbered OFDMA symbol.

c) Continue the mapping so that the OFDMA subchannel index is increased. When the edge of the data region is reached, continue the mapping from the lowest numbered OFDMA subchannel in the next available symbol.

UL:

The UL mapping consists of two steps. In the first step, the OFDMA slots allocated to each burst are selected. In the second step, the allocated slots are mapped.

Step 1—Allocate OFDMA slots to bursts.

1) Segment the data into blocks sized to fit into one OFDMA slot.
2) Each slot shall span one subchannel in the subchannel axis and one or more OFDMA symbols in the time axis, as per the slot definition in 8.4.3.1 (see Figure 221 for an example). Allocate the slots so that the lowest numbered slot occupies the lowest numbered OFDMA symbol in the lowest numbered subchannel.
3) Continue allocating such that the OFDMA symbol index is increased (skipping allocations made with UIUC=0, UIUC=11 (Extended-2 UIUC) with Type=8, 12, 13; see 8.4.5.4). When the edge of the UL zone (which is marked with Zone IE) is reached, continue allocating from the lowest numbered OFDMA symbol in the next available subchannel.
4) An UL allocation is created by selecting an integer number of contiguous slots, according to the ordering of items d) through f). This results in the general Burst structure shown by the gray area in Figure 221.

Step 2—Map OFDMA slots within the UL allocation.

5) Map the slots so that the lowest numbered slot occupies the lowest numbered subchannel in the lowest numbered OFDMA symbol.
6) Continue the mapping so that the subchannel index is increased. When the last subchannel is reached, continue the mapping from the lowest numbered subchannel in the next OFDMA symbol that belongs to the UL allocation. The resulting order is shown by the arrows in Figure 221.

The subchannels referred to in this subclause are logical subchannels, before subchannel renumbering in the DL, and before applying the rotation scheme (8.4.6.2.6) and the mapping indicated by UL allocated subchannels bitmap in UCD for the UL.

Figure 220 and Figure 221 illustrate the order in which OFDMA slots are mapped to subchannels and OFDMA symbols.
Figure 220—Example of mapping OFDMA slots to subchannels and symbols in the DL (in PUSC mode)
In licensed bands, the duplexing method shall be either FDD or TDD. FDD SSs may be full-duplex (FDD) or half-duplex (H-FDD). The FDD BS shall support both SS types concurrently. In license-exempt bands, the duplexing method shall be TDD.

### 8.4.4 TDD frame structure

When implementing a TDD system, the frame structure is built from BS and SS transmissions. Each frame in the DL transmission begins with a preamble followed by a DL transmission period and an UL transmission period. In each frame, the TTG and RTG shall be inserted between the DL and UL and at the end of each frame, respectively, to allow the BS to turn around.

---

**Figure 221—Example of mapping OFDMA slots to subchannels and symbols in the UL**
Figure 222 shows an example of an OFDMA frame (with only mandatory zone) in TDD mode.

**Figure 222—Example of OFDMA frame (with only mandatory zone) in TDD mode**

### 8.4.4.2 FDD frame structure

Base stations of OFDMA FDD systems shall operate in full duplex mode. SSs shall be either full duplex (FDD) or half duplex (H-FDD). The FDD frame structure supports both FDD and H-FDD SS types. The frame structure supports a coordinated transmission arrangement of two groups of H-FDD SSs (Group-1 and Group-2) that share the frame at distinct partitions of the frame.

Figure 223 and Figure 224 show the frame structure of an OFDMA FDD system that supports the concurrent operation of H-FDD and FDD SSs. The DL frame contains two subframes. DL Subframe 1 comprises a preamble symbol, a MAP region (MAP1) and data symbols (DL1). DL Subframe 2 comprises a MAP region (MAP2) and data symbols (DL2).

The space between the two DL subframes is occupied by a gap DL Gap (see Figure 223), the size of which shall be an integer number of symbols (0, 1, 2, 3). Optionally, as shown in Figure 224, this gap may also include the residual frame time, DL residue (the frame duration minus the total time occupied by the frame symbols). The number of symbols in DL Gap and the location of DL residue shall be signaled in the DCD, in both DL subframes, using the “FDD DL gap” TLV (see 11.4.1 Table 575). The BS shall not change the location and value of DL residue during operation.

The UL frame contains two subframes, UL2 and UL1 (in this order). Figure 223 and Figure 224 show the timing relationship of the UL subframes relative to the DL subframes. The four parameters TTG1, TTG2, RTG1 and RTG2 are announced in the DCD messages (see Table 575) and they shall be sufficiently large to accommodate the H-FDD SSs transmit receive switching time plus the round trip propagation delay.
Group-1 H-FDD SSs listen to DL Subframe 1 and transmit in uplink subframe UL1. Group-2 H-FDD SSs listen to DL Subframe 2 and transmit in uplink subframe UL2. No uplink transmission by any H-FDD SS is allowed during the preamble transmission. All FDD SSs may transmit during the preamble transmission.

The MAP regions—MAP1 and MAP2—are independent and include FCH, DL-MAP and UL-MAP, the definitions of which are provided in 8.4.4.4, 8.4.5.3, and 8.4.5.4 respectively.

![Generic OFDMA FDD frame structure supporting H-FDD MS in two groups with residual at the end of the frame](image-url)
Figure 224—Generic OFDMA FDD frame structure supporting H-FDD MS in two groups with residual between the downlink subframes

Figure 225 and Figure 226 illustrate the time relevance of the MAPs in Group 1 and Group 2.

Figure 225—Time relevance of DL-MAP and UL-MAP for H-FDD group 1
8.4.4.2.1 Group Switching

In FDD, for H-FDD MSs, the BS shall be able to switch a user (MS) from group-1 to group-2, or vice versa at its discretion. To effectuate a group switch, the BS shall use any one of the following:

a) H-FDD Group Switch IE (8.4.5.3.28)

b) DL HARQ Chase Subburst IE
c) DL HARQ IR CTC Subburst IE
d) DL HARQ IR CC Subburst IE
e) Subburst IEs of the Persistent HARQ DL MAP IE
f) Subburst IEs of the Persistent HARQ UL MAP IE

When using the H-FDD Group Switch IE method, the BS shall use the Group Indicator field to signal the H-FDD group index that the MS should be associated with. If the Group Indicator field is not equal to the current H-FDD MS’s group index, the mobile station shall switch to the group whose index is indicated by the Group Indicator field.

When an MS is instructed to switch to the opposite group, it shall deem any existing periodic CQICH allocations and any persistent allocation as being de-allocated by the BS.

The BS may request the MS to explicitly acknowledge a group switch instruction, in which case the BS shall assign a one-time MAP ACK channel. For items b), c), and d), the one-time CQICH channel shall be allocated via setting the LSB #0 of the Dedicated DL Control Indicator to 1 and using the Allocation Index field to indicate the location.

When the H-FDD Group Switch IE is used for signaling a group switch, a one-time CQICH channel may be assigned in that IE (see 8.4.5.3.28). In case the BS includes a one-time CQICH allocation in the IE that contains the group switch instruction, the MS shall acknowledge reception of the instruction—with a MAP ACK command, as described in 8.4.11.16—in the assigned CQICH channel.

If the group switch completion time TLV is included in the UCD message and the MS cannot join the new group within the group switch completion time as broadcasted in the TLV, the MS shall go to Group 1 and initiate an uplink communication with the BS. The BS shall interpret such communication as an indication from the MS that it failed to execute the group switch instruction.
After the MS receives a group switch instruction in frame $n$, the MS shall switch to the new group and decode the downlink subframe in frame $n + H\text{-FDD\_Group\_Switch\_Delay} + m$, where $m$ denotes the current group number (1 or 2) and $H\text{-FDD\_Group\_Switch\_Delay}$ is specified in the UCD (H-FDD Group Switch Delay). The MS may ignore the downlink subframe of the current group in frame $n + H\text{-FDD\_Group\_Switch\_Delay} + 1$ (the subframe immediately preceding the transition). See Figure 227. After switching groups, the MS should initiate an uplink communication with the BS to confirm the success of group switch operation.

To avoid signaling overhead to re-define the PSC for H-FDD users after every group switch, the use of the “Sleep mode follows MAP relevance” capability (see 11.16.2) is recommended.

8.4.4.2.2 Frame partition signaling

In H-FDD operation, the BS shall indicate the number of symbols in DL Subframe 1 of the current frame (Figure 223) using the “No OFDMA Symbols” field in DL-MAP1 of the current frame (see 6.3.2.3.2). Additionally, the BS shall indicate the number of symbols in DL Subframe 2 of the next frame, using the “No OFDMA Symbols” field in DL-MAP2 of the current frame.

For the UL, the BS shall indicate, in the “No. OFDMA symbols” in UL-MAP1 and UL-MAP2, the size of UL1 of the next frame and the size of UL2 of the next-next ($n+2$) frame respectively. Thus, DL-MAP and UL-MAP in frame $n$ provide partition information for frame $n+1$ and $n+2$.

If an H-FDD MS misses two or more consecutive MAP messages (due to MAP decoding errors, sleep mode, etc.), the H-FDD MS may no longer have valid frame partition information. When a H-FDD MS no longer has valid frame partition information, the MS shall listen to MAP1 in order to receive updated partition information.

---

Figure 227—H-FDD Group transition scenarios
The frame parameters broadcast by the BS shall allow the SS to locate DL Subframe 2 using any of the following formulas.

NOTE—PS index value 1 is the first PS of the Preamble symbol.

\[
\text{Index of first PS of DL Subframe 2} = (\text{Symbols\_Frame} - \text{Symbols\_DL2}) \times \text{PS\_1Symbol} + Z + 1
\]
\[
= (\text{Symbols\_DL1} + \text{DL\_gap}) \times \text{PS\_1Symbol} + Z + 1
\]
\[
= (1 + \text{Symbols\_UL2}) \times \text{PS\_1Symbol} + \text{TTG2} + \text{RTG2} + 1
\]

Number of symbols in DL Subframe 2
\[
= \text{Symbols\_DL2}
\]
\[
= \text{Symbols\_Frame} - \text{Symbols\_DL1} - \text{DL\_gap}
\]

See 8.4.4.2.4 and 8.4.4.2.5 for more information on DCD and UCD content in FDD/H-FDD.

**8.4.4.2.3 Full Duplex Support**

Two alternative solutions may be used as defined in 8.4.4.2.3.1 and 8.4.4.2.3.2.

**8.4.4.2.3.1 Full Duplex Support with FDD paired allocation IE**

The BS may allocate resources in both H-FDD groups to full duplex mobile stations using the FDD paired allocation IE as described in 8.4.5.4.29.

**8.4.4.2.3.2 Full Duplex Support with aggregated HARQ channels**

Full duplex mobile stations may negotiate aggregated HARQ channels with the base station using the Aggregated HARQ Channels TLV. If the mobile station and base station negotiate aggregated HARQ channels, then these HARQ channels shall be treated as a paired set of HARQ channels for transmission and reception of bursts. The two HARQ channels in the paired set are denoted the first HARQ channel and the second HARQ channel (ACID\(_1\) and ACID\(_2\) in the Aggregated HARQ Channels TLV).

If the base station transmits an IE containing the first HARQ channel from an aggregated pair in the MAP of group 1 of frame \(K\), then the BS shall transmit an IE containing the second HARQ channel from an aggregated pair in the MAP of group 2 of frame \(K\). If the BS transmits an IE containing the first HARQ channel from an aggregated pair in the MAP of group 2 of frame \(K\), then the BS shall transmit an IE
containing the second HARQ channel from an aggregated pair in the MAP of group 1 of frame \(K+1\). The FDD MS monitors the MAP of group 1 and the MAP of group 2 to determine its allocation.

For DL operation, the BS shall separate a single burst into the resources corresponding to the first and second HARQ channels at the physical layer, and the MS shall aggregate the resources corresponding to the first and second HARQ channels at the physical layer as a single burst prior to decoding.

For UL operation, the MS shall separate a single burst into the resources corresponding to the first and second HARQ channels at the physical layer, and the BS shall aggregate the resources corresponding to the first and second HARQ channels at the physical layer as a single burst prior to decoding.

The total number of slots used for the burst shall be set to the number of slots assigned for the first HARQ channel plus the number of slots assigned for the second HARQ channel. The burst shall be mapped to the entire set of slots in the H-FDD group corresponding to the first HARQ channel before being mapped to the slots in the opposite H-FDD group corresponding to the second HARQ channel.

The base station shall set the modulation and coding indications (DIUC, Repetition Coding Indication, \(N_{EP}\)) and the HARQ channel indications (\(AI_{SN}, SPI\)) for the bursts corresponding to the aggregated HARQ channels to the same value.

### 8.4.4.2.4 DCD

For a particular configuration change count, the DCD message transmitted in H-FDD group 1 shall be equal to the DCD message transmitted in H-FDD group 2. In a given frame, the DCD count in the DL-MAPs of both groups shall be the same.

### 8.4.4.2.5 UCD

For a particular configuration change count, the UCD message transmitted in H-FDD group 1 shall be equal to the UCD message transmitted in H-FDD group 2. The UCD count in the UL-MAP of group 2 of frame \(N\) shall be equal to the UCD count in the UL-MAP of group 1 of frame \(N+1\).

### 8.4.4.3 OFDMA Frame Parameters and Operations

SS allowances shall be made by a SSRTG and by a SSTTG. The BS shall not transmit DL information to a station later than (SSRTG + RTD) before the beginning of its first scheduled UL allocation in any UL subframe and shall not transmit DL information to it earlier than (SSTTG – RTD) after the end of the last scheduled UL allocation, where RTD denotes round-trip delay. In addition, the SS should be allowed to receive the DL preamble for each frame that contains DL data for it by assuring the period specified above does not overlap with the preamble. If the BS transmits the UL_initial_transmit_timing TLV in the UCD, the SSs transmit timing shall be referenced to the value indicated by this TLV. Otherwise, the SSs transmit timing shall be referenced to the ‘UL Allocation Start Time’ value specified by the UL-MAP. The parameters SSRTG and SSTTG are capabilities provided by the SS to BS upon request during network entry (see 11.8.3.1).

Subchannel allocation in the DL may be performed in the following ways: partial usage of subchannels (PUSC) where some of the subchannels are allocated to the transmitter and full usage of the subchannels (FUSC) where all subchannels are allocated to the transmitter. The FCH shall be transmitted using QPSK rate 1/2 with four repetitions using the mandatory coding scheme (i.e., the FCH information shall be sent on four subchannels with successive logical subchannel numbers) in a PUSC zone. The FCH contains the DL frame prefix as described in 8.4.4.4, and specifies the length of the DL-MAP message that immediately follows the DL frame prefix and the repetition coding used for the DL-MAP message.
The transitions between modulations and coding take place on slot boundaries in time domain (except in AAS zone) and on subchannels within an OFDMA symbol in frequency domain.

The OFDMA frame may include multiple zones (such as PUSC, FUSC, PUSC with all subchannels, optional FUSC, AMC, TUSC1, and TUSC2), the transition between zones is indicated in the DL-Map by the STC_DL_Zone IE (see 8.4.5.3.4) or AAS_DL_IE (see 8.4.5.3.3). No DL-MAP or UL-MAP allocations can span over multiple zones. Figure 228 depicts the OFDMA TDD frame with multiple zones.

The PHY parameters (such as channel state and interference levels) may change from one zone to the next. More than one DL or UL zone may be defined for each configuration (e.g., permutation, STC mode, PermBase, etc). For example, zones may be used for defining partitions in time for an FDD/H-FDD system.

The following restrictions apply to DL allocations:

a) The maximum number of DL zones is 8 in one DL subframe.
b) For each SS, the maximum number of bursts to decode in one DL subframe is 64. This includes all bursts without CID or with CIDs matching the SS’s CIDs.
c) For each MS, the maximum number of bursts transmitted concurrently and directed to the MS is limited by the value specified in Max_Num_Bursts TLV (including all bursts without CID or with CIDs matching the MSs CIDs). Bursts transmitted concurrently are bursts that share the same OFDMA symbol. Before the MS completes capability exchange, the BS shall transmit data to the MS in the first concurrent data burst per symbol.

If the BS allocates more bursts or zones, then the SS is required to decode the first bursts/zones until the limit is reached.

The precedence of UL and DL transmissions for H-FDD mode is defined as follows:

1) For FDD/H-FDD operation, overlapping allocations are defined as DL and UL allocations in which the time difference from the end of the DL allocation to the beginning of the UL allocation, measured at the MS antenna port, is less than SSRTG, or the time difference from the end
of the UL allocation to the beginning of the DL allocation, measured at the MS antenna port, is less than SSTTG. For UL control channels (UL ranging/BW-request, FAST-Feedback, ACKCH region, sounding, etc.), the overlapping allocation applies to the region, i.e., a downlink allocation that overlaps a region is considered to overlap all slots and opportunities in the region.

2) In H-FDD, overlapping allocations of bursts explicitly directed to the MS (by basic CID in the DL/UL map) are not allowed.

The number of symbols in an STC zone (not including the midamble) shall divide by the number of symbols in any MIMO matrix used in the zone. In addition, the STC zone shall include at least one full period of the pilot pattern defined for the relevant permutation and the number of antennas.

### 8.4.4.4 DL frame prefix

The DL_Frame_Prefix is a data structure transmitted at the beginning of each frame and contains information regarding the current frame and is mapped to the FCH. Table 314 defines the structure of DL_Frame_Prefix except for the case of 128-FFT.

<table>

**Used subchannel bitmap**

A bitmap indicating which groups of subchannel are used on the first PUSC zone and on PUSC zones in which ‘Use All SC’ field is set to ‘0’ in STC_DL_Zone_IE(). A value of 1 means used by this segment, and ‘0’ means not used by this segment.
Repetition_Coding_Indication
Indicates the repetition code used for the DL-MAP. Repetition code may be 0 (no additional repetition), 1 (one additional repetition), 2 (three additional repetitions) or 3 (five additional repetitions).

Coding_Indication
Indicates the FEC encoding code used for the DL-MAP. The DL-MAP shall be transmitted with QPSK modulation at FEC rate 1/2. The BS shall ensure that DL-MAP (and other MAC messages required for SS operation) are sent with the mandatory coding scheme often enough to ensure uninterrupted operation of SS supporting only the mandatory coding scheme.

DL-Map_Length
Defines the length in slots of the burst which contains only DL-MAP message or compressed DL-MAP message and compressed UL_MAP, if it is appended, that follows immediately the DL frame prefix after repetition code is applied.

The subchannel index of the six subchannel groups is shown in Table 315.

Before being mapped to the FCH, the 24-bit DL frame prefix shall be duplicated to form a 48-bit block, which is the minimal FEC block size.

</table>

Before being mapped to the FCH, the 12-bit DL frame prefix shall be repeated four times to form a 48-bit block, which is the minimal FEC block size.

8.4.4.5 Allocation of subchannels for FCH and DL-MAP and logical subchannel numbering

In PUSC, any segment used shall be allocated at least the same number of subchannels as in subchannel group #0. For FFT sizes other than 128, the first 4 slots in the DL part of the segment contain the FCH as defined in 8.4.4.1. These slots contain 48 bits modulated by QPSK with coding rate 1/2 and repetition coding of 4. For 128-FFT, the first slot in the DL part of the segment is dedicated to FCH, and repetition is not applied. The basic allocated subchannel sets for segments 0, 1, and 2 are subchannel group #0, #2, and #4, respectively. Figure 229 depicts this structure.

After decoding the DL_Frame_Prefix message within the FCH, the SS has the knowledge of how many and which subchannels are allocated to the PUSC segment. In order to observe the allocation of the subchannels in the DL as a contiguous allocation block, the subchannels shall be renumbered. For the first PUSC zone, the renumbering shall start from the FCH subchannels (renumbered to values 0…11) and then continue numbering the subchannels in a cyclic manner to the last allocated subchannel and from the first allocated subchannel to the FCH subchannels. Figure 230 gives an example of such renumbering for segment 1. For other PUSC zones in which the Use All SC field is set to 1 or that are defined by AAS_DL_IE() renumbering shall be performed starting from subchannel \((N_{subchannels}/3)\times PRBS_ID\), where PRBS ID is specified in the STC DL Zone IE or AAS_DL_IE(). For other PUSC zones in which the Use All SC field is set to 0, the renumbering shall be the same as in the first PUSC zone. For downlink AMC permutation, the subchannel renumbering shall start from 0 and shall be done in increasing order of frequency index of the used physical bands, as described in ‘DL AMC allocated physical bands bitmap’ in the DCD.
Figure 229—FCH subchannel allocation for all 3 segments
For UL, in order to observe the allocation of the subchannels as a contiguous allocation block, the subchannels shall be renumbered. The renumbering shall start from the lowest numbered allocated subchannel (renumbered to value 0) and continue up to the highest numbered allocated subchannel, skipping nonallocated subchannels. Figure 231 gives an example of such renumbering for segment 1. For uplink AMC permutation, the subchannel renumbering shall start from 0 and shall be done in increasing order of frequency index of the used physical bands, as described in ‘UL AMC allocated physical bands bitmap’ in the UCD.
The DL-MAP of each segment shall be mapped to the slots allocated to the segment in a frequency-first order, starting from the slot after the FCH (subchannel 4 in the first symbol, after renumbering) and continuing to the next symbols if necessary. The FCH of segments that have no subchannels allocated (unused segments) shall not be transmitted, and the respective slots may be used for transmission of MAP and/or data of other segments.

8.4.4.6 UL transmission allocations

The allocation for a user UL transmission is a number of subchannels over a number of OFDMA symbols. The basic allocation structure is a slot, as defined in 8.4.3.1.

The framing structure used for the UL includes an allocation for ranging and an allocation for data transmission. The MAC sets the length of the UL framing and the UL mapping.

In the UL, the BS shall not allocate to any SS more than one UL-MAP IE with data burst profile UIUC (1–10) in a single frame. In the UL, the BS shall not allocate to any MS more than one mini-subchannel allocation in a single frame. These limitations do not apply to HARQ data allocation regions.

For TDD mode, the BS shall not allocate more than three ranging allocation IEs (UIUC 12) per frame:

- One for initial ranging/HO ranging (Dedicated Ranging Indicator bit in UL-MAP IE is set to 0 and Ranging Method is set to 0b00 or 0b01)
— One for BR/periodic ranging (Dedicated Ranging Indicator bit in UL-MAP IE is set to 0 and Ranging Method is set to 0b10 or 0b11)
— One for initial ranging for the paged MS, location measurement and/or coordinated association (Dedicated Ranging Indicator bit in UL-MAP IE is set to 1)

For FDD/H-FDD mode, the BS may allocate up to 2 ranging regions of each type (up to 6 regions altogether).

Rectangular allocations made with UIUC = 0, 11 (Extended-2 UIUC) with Type = 8, 12, 13 shall not break the UL tile structure, shall not span over multiple zones, and shall conform to the following rules:

a) In each subchannel, the size of each continuous group of OFDMA symbols remaining after allocation of UIUC = 0, 11 (Extended-2 UIUC) with Type = 8, 12, 13 regions shall be a multiple of three OFDMA symbols. For UIUC = 12, the sum of ranging allocations (in units of OFDMA symbols) shall be a multiple of 3 symbols.

b) The slot boundaries in all subchannels shall be aligned, i.e., if a slot starts in symbol \( k \) in any subchannel, then no slots are allowed to start at symbols \( k + 1, k + 2 \) at any other subchannel.

c) The number of UL symbols (excluding AAS preambles and Sounding zone (UIUC=13)) per zone shall be an integer multiple of slot duration. Data bursts, Fast Feedback and ACK channels shall always start on a slot boundary.

Figure 232 depicts examples of correct and incorrect allocations of regions with UIUC = 0, 11 (Extended-2 UIUC) with Type = 8, 12, 13. Each rectangle is an UL subframe (or zone). Regions 1, 2, and 3 are correct allocations, while regions 4 and 5 are incorrect allocations.

![Figure 232—Example of rectangular allocation rules](image-url)
8.4.4.7 Optional AAS support

AAS support is indicated by the AAS_DL_IE and AAS_UL_IE in the downlink and uplink broadcast maps. The AAS_IE specifies an AAS zone, which is defined as a contiguous block of OFDMA symbols that has a defined permutation and preamble structure. Multiple AAS zones can be supported within a frame. Each AAS zone may or may not contain an optional Diversity-Map Scan zone. AAS Operation without the optional Diversity-Map Scan zone is referred to as Basic AAS Mode.

8.4.4.7.1 AAS frame structure

An AAS DL zone begins on the specified symbol boundary and consists of all subchannels until the start of the next zone or end of frame. The two highest numbered subchannels of the DL frame may be dedicated at the discretion of the BS for the AAS diversity map zone in PUSC, FUSC, and optional FUSC permutation.

The AAS Diversity-MAP zone shall be used only with FFT sizes greater than or equal to 512.

In the AMC permutation, the first and last subchannels of the AAS DL zone may be dedicated at the discretion of the BS for the AAS Diversity-MAP Zone. When subchannels are used for a diversity map zone, they shall not be allocated in the normal DL-MAP message. These subchannels shall be used to transmit the AAS-DLFP() whose physical construction is shown in Figure 233. In the case that the AAS Diversity-MAP zone is not included in the AAS zone, these subchannels may be used for ordinary traffic and may be allocated in DL-MAP messages.

A 2-bin-by-3-symbol tile structure shall be used for all AMC permutations in an AAS zone, including the optional AAS Diversity-MAP zone.

Figure 233—Example of allocation for AAS-DLFP

A 2-bin-by-3-symbol tile structure shall be used for all AMC permutations in an AAS zone, including the optional AAS Diversity-MAP zone.
In the AAS zone, the same antenna beam pattern shall be used for all pilot subcarriers and data subcarriers in a given AMC subchannel.

In an AAS zone defined with the PUSC permutation, the SS may assume that the entire major group is beamformed so that the channel may vary slowly within the major group over the entire duration of the zone.

The AAS portion in the DL (or UL) may be transmitted either by the FUSC/PUSC permutation or by the optional AMC permutation. Figure 234 shows an example of a DL subframe for each of these two possible variations.

![Figure 234—AAS Diversity-MAP frame structure](image)

### 8.4.4.7.2 Optional Diversity-Map scan

The purpose of the AAS-DLFP is to provide a robust transmission of the required BS parameters to enable SS initial ranging, as well as SS paging and access allocation. This is achieved through using a highly robust form of modulation and coding (namely QPSK-1/2 rate with 2 repetitions). The start of an AAS-DLFP is marked by an AAS DL preamble. The AAS-DLFPs transmitted within the AAS Diversity-MAP Zone may, but need not, carry the same information. Different beams may be used within the AAS Diversity-MAP Zone; however, each AAS DL preamble and associated AAS-DLFP shall be transmitted on the same beam.

The UL and DL AAS zones are defined by the UL and DL extended AAS-IE in the broadcast map. In the case that an SS cannot successfully decode the broadcast maps, the SS shall scan for the DLFP messages and utilize private maps within the AAS zone. It is assumed that all AAS subscribers will be able to determine the IDcell used in the selection of the DL preamble at the beginning of the DL frame. This IDcell shall be
used as the DL_PermBase for the AAS zone. The UL_PermBase for the UL zone referred to by the initial ranging allocation in the AAS-DLFP shall be that provided in the UCD message. AAS subscribers that cannot detect the AAS DL IE transmitted in the DL-MAP, which specifies the boundaries and permutation of AAS DL zones, shall search over the possible permutations (PUSC/FUSC/AMC) and starting symbol to detect the AAS-DLFP. The permutation for the AAS UL zone is specified by a field in the AAS-DLFP.

The AAS-DLFP supports the ability to transmit a compressed DL-MAP IE. This allocation message can point to a broadcast DL-MAP that is beamformed or can be used to “page” a specific SS that cannot receive the normal DL-MAP. Once the initial allocations are provided to the user, private DL-MAPs and UL-MAPs can be sent on a beamformed transmission to the user at the highest modulation and highest coding rate that can be supported by the link. The AAS-DLFP also has an UL initial ranging allocation for AAS subscribers. The AAS-DLFP is not randomized.

The preamble length specified by the Downlink_Preamble_Config field should be limited to an integer number of slot durations for the DL PUSC permutation. Further, this field determines the preamble duration for the allocation pointed to by the DL Comp IE in the AAS-DLFP and shall be consistent with the preamble lengths described in the AAS DL IE messages.

The contents of the AAS-DLFP() payload is described by Table 317.

The structure for AAS Comp DL IE is described in Table 318.

8.4.4.7.3 AAS diversity scan map network entry procedure

The AAS network entry utilizing the DLFP involves the following procedure:

— The AAS-SS synchronizes frame timing and frequency to the frame-start DL preamble.
— For AAS-SS at cell edge, which cannot decode the FCH or broadcast DL-MAP and UL-MAP messages, they will search for the AAS-DLFP on the AAS Diversity-MAP Zone. This search will need to span the possible subchannel permutations.
— The AAS-SS may receive necessary messages such as the DCD and UCD pointed to by allocations made from the AAS-DLFP using the Broadcast CID. These messages may be transmitted using beam-pattern diversity to increase the link budget.
— Once the AAS-SS decodes the DCD and UCD it should perform initial ranging on the interval pointed to by the best-received AAS-DLFP.
— The AAS-SS may receive a ranging response message through a DL-MAP allocation pointed to by an AAS-DLFP with the Broadcast CID.
— The AAS-SS may receive initial DL allocations through a DL-MAP allocation pointed to by the AAS-DLFP with either Broadcast CID or specific CID.
— Subsequent allocations can be managed with private DL-MAP and UL-MAP allocations.

8.4.4.7.4 AAS preambles

AAS preambles are used to provide training information in both UL and DL AAS zones. All data allocations (UIUC 1-10, DIUC 0-12) and the optional AAS DLFP in an AAS zone are preceded by an AAS preamble.

UL and DL allocations are made exclusive of the AAS preamble. In the DL, a 2D allocation burst is preceded by the appropriate DL AAS preamble. In the UL, a 1D allocation is preceded by the appropriate AAS preamble. The absolute slot offset for the UL AAS allocation indicates the first data slot, which is preceded by the appropriate AAS preamble. If an UL allocation wraps at the end of the AAS zone, the data allocation does not include the symbols required for the initial AAS zone preambles.

In case the UL AAS zone length is equal to the number of symbols assigned to the AAS preamble, then no data slots are transmitted in the zone. In this case, the Slot Offset field in the UL-MAP IE shall be interpreted

as the logical subchannel from which to start transmitting preambles. The Duration field in the UL-MAP IE shall be interpreted as the number of subchannels on which to send the preamble.

The optional AAS-DLFP is preceded by an AAS DL preamble of one symbol duration. All other DL bursts with DIUC 0-12 within an AAS DL zone have a preamble whose duration is specified by the Downlink_Preamble_Config fields of the AAS DL IE. This field shall be consistent with the same field of the AAS-DLFP if present. In the case the AAS DL zone is using the PUSC permutation, the Downlink_Preamble_Config field shall always be set to an integer number of slot durations (i.e., 0 or 2 symbols).

An UL preamble is inserted at the start of an UL data allocation with UIUC 1–10 and whenever such an UL allocation wraps from the end of an AAS zone to the beginning. The first Uplink_Preamble_Config symbols of the UL AAS zone are reserved for UL AAS preambles. On a given subchannel, an UL AAS preamble will be inserted into these symbols by the SS devices who is allocated the slot following the preamble (or following a UIUC 0,12,13 region if it directly follows the preamble). Any UL preamble inserted in an AAS zone in a location other than the first Uplink_Preamble_Config symbols shall be 3 symbols in duration.

The absolute slot offset field in the UL-Map IE corresponds to the first data slot of an allocation, which is preceded by the appropriate number of symbols for the UL AAS preamble. The absolute slot offset will count from the first subchannel slot, counting all slots in an AAS zone including any UIUC 0,12,13 regions. The slot offset will not include the first Uplink_Preamble_Config preamble symbols at the start of the AAS zone.

The duration of an UL AAS zone minus the reserved UL preamble symbols and any UIUC 0,12,13 allocations shall be an integer number of slots. To insure that UL tile structures are not broken due to an allocation wrapping, the following restrictions hold:

- When used in an AAS zone, a UIUC 0,12,13 region shall be a multiple of three symbols in duration.
- An UL AAS zone shall consist of an integer number of slots plus the number of UL AAS preamble symbols as defined in by the Uplink_Preamble_Config field of the UL AAS IE and AAS-DLFP.
— UL AAS zone duration = $N \times 3 + \text{Uplink}_\text{Preamble}_\text{Config}$ symbols.
— Fast-feedback channels shall be allocated an integer number of slots.

Figure 235 shows a legal UL AAS zone with an UIUC 12,13 allocation that is an integer number of slots in duration.

![Diagram of UL AAS allocation with integer number of slots in duration]

The structure of the preambles is as specified in 8.4.4.7.4.1 and 8.4.4.7.4.2 for the DL and UL, respectively. The preamble may be either time or frequency shifted according to a preamble shift index as defined in 8.4.5.3.11 and 8.4.5.4.12. The preamble shift index shall be set by the PHY MOD DL IE and PHY MOD UL IE, for DL and UL, respectively. The preamble shift index shall also be set by the AAS beam index carried by the AAS-DLFP(), in which case it shall apply to all subsequent DL allocations until a PHY MOD DL IE is received. The BS shall ensure that all shift index specifications for an allocation (e.g., in private maps, AAS-DLFP, broadcast maps) are consistent. When using the cyclic time-shifted or frequency-shifted preamble defined in 8.4.5.3.11 and 8.4.5.4.12, beams that use the same subchannels at the same time instance shall be configured to use a different preamble shift index.

### 8.4.4.7.4.1 AAS DL preamble

A basic AAS DL preamble is formed by concatenating the sequences from the three carrier sets defined in 8.4.6.1.1. Let the PN sequence for the $m$-th preamble carrier set ($m = 0, 1, 2$) defined in 8.4.6.1.1 have length $N$ bits. The $k$-th bit of the basic AAS preamble sequence $P$ is given by Equation (57).

$$P_k = W_n (m \mod 3) \quad (57)$$

where
\[ m = \left\lfloor \frac{k}{N} \right\rfloor \mod 3 \]
\[ n = k \mod N \]
\[ W_n(m) \text{ is the } n\text{-th bit of the PN sequence for the } m\text{-th preamble carrier-set defined in 8.4.6.1.1} \]

The preamble sequence shall correspond to a IDcell equal to \((ID_c + 16) \mod 32\) (where \(ID_c\) is the IDcell determined from the DL preamble). The bits \(P_k\) shall be mapped to values consistent with the specification in 8.4.6.1.1 (0 mapped to +1, 1 mapped to –1).

The AAS preamble sequence length is \(N_{used}\) bits and it shall be mapped starting from the first usable subcarrier, according to the permutation. The DC carrier shall not be modulated and the corresponding bit in the constructed preamble sequence shall be discarded.

The AAS preamble used for the burst shall be a subset of this basic preamble sequence corresponding to the subcarriers used by the burst’s subchannels. In the AMC allocation, the basic AAS preamble occupies nine subcarriers in each bin of the subchannels. The number of symbols occupied by the preamble is set by the Downlink_Preamble_Config field in the AAS_DL_IE(). The AAS preamble is formed by copying the basic preamble onto the consecutive preamble symbols. The AAS preamble shall be placed, for each subchannel, starting from the first OFDMA symbol for that subchannel that belongs to the burst.

DL pilot locations are shifted forward with the burst allocation in time in the AMC zone with the following rules: pilot index = 9\(k + 3m + 1\) where \(k\) is a bin index and \(m\) = symbol index mod 3. The symbol index starts at zero for each AAS zone and corresponds to the first symbol in the AAS zone (if AAS preamble is not present) or the first symbol following the AAS preamble (if AAS preamble is present).

### 8.4.4.7.4.2 AAS UL preamble

The basic AAS UL preamble is formed by the method defined in 8.4.4.7.4.1 using the IDcell (as determined from the preamble). This subset shall correspond to the subcarriers used by the burst’s subchannels. In the AMC allocation, the basic AAS preamble occupies nine subcarriers in each bin of the subchannels. The number of symbols occupied by the preamble is set by the Uplink_Preamble_Config field in the AAS_UL_IE(). The AAS preamble is formed by copying the basic preamble onto the consecutive preamble symbols. The AAS preamble shall be placed, for each subchannel, starting from the first OFDMA symbol for that subchannel that belongs to the burst.

Any UL allocation that wraps from the last OFDMA symbol of the AAS zone to the first OFDMA symbol shall have a preamble inserted in the first \(N\) OFDMA symbols of the AAS zone, where \(N\) is the number of AAS preamble symbols for the burst defined by the Uplink_Preamble_Config field of either the AAS UL IE or the AAS-DLFP.

The Tx power level of UL AAS preamble is equal to that of data subcarrier determined by Equation (131) or Equation (132), as appropriate, in 8.4.10.3, when the required \((C/N)\) value of the current transmission, excluding code repetition factor, is between the predefined lower bound and the predetermined upper bound. Otherwise, the Tx power level of UL AAS preamble is boosted or reduced. The predefined LowerBound\_AAS\_PREAMBLE and UpperBound\_AAS\_PREAMBLE are broadcast in the UCD TLV. Thus, Tx power level of AAS preamble can be determined as shown in Equation (58).
where

\[ P_{\text{Data}} \] is Tx power level (dBm) per subcarrier for current data transmission determined by Equation (135) in 8.4.10.3

\( (C/N) \) is required normalized C/N of the modulation/FEC rate for the current transmission in Table 514

\( R \) is the number of repetitions for the modulation/FEC rate

When SS does not have enough power to boost up AAS preamble, the power of AAS preamble is set equal to data symbol power. The power control of the UL AAS preamble is normally disabled by setting the initial values of LowerBound_{AAS_PREAMBLE} and UpperBound_{AAS_PREAMBLE} equal to –32 dB, 31.75 dB, respectively. The SS that does not support preamble power control set the AAS preamble power equal to that of data symbols.

8.4.5 Map message fields and IEs

8.4.5.1 DL-MAP PHY Synchronization field

The format of the PHY Synchronization field of the DL-MAP message, as described in 6.3.2.3.2 or Compressed_DL-MAP, as defined in 8.4.5.6, is given in Table 319. The frame duration codes are given in Table 320. The frame number is incremented by one each frame and eventually wraps around to zero.

<table>
<thead>
<tr>
<th>Table 319—OFDMA PHY Synchronization Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
</tr>
<tr>
<td>PHY_synchronization_field()</td>
</tr>
<tr>
<td>Frame Duration Code</td>
</tr>
<tr>
<td>Frame Number</td>
</tr>
</tbody>
</table>

A BS shall generate DL-MAP messages in the format shown in Table 40, including all of the following parameters:

Frame number
The frame number is incremented by 1 MOD 2^{24} each frame.

Frame Duration Code
The frame duration code values are specified in Table 320.
8.4.5.2 Frame duration codes

Table 320 defines the various frame durations that are allowed. The frame durations defined in the table indicate the periodicity of the DL frame start preamble in both FDD and TDD cases.

Table 320—OFDMA frame duration ($T_f \text{ms}$) codes

<table>
<thead>
<tr>
<th>Code (N)</th>
<th>Frame duration (ms)</th>
<th>Frames per second</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Reserved</td>
<td>N/A</td>
</tr>

</tr>
<tr>
<td>8</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>9–255</td>
<td>Reserved</td>
<td></td>
</tr>
</tbody>
</table>

Note that the frame durations indicated in Table 320 typically are not integer multiples of one OFDMA symbol duration. Therefore some time padding may be necessary between the last useful OFDMA symbol of a frame and the beginning of the next frame. In addition, in the TDD case, note that the RTG and TTG guard intervals shall be included in a frame. Both RTG and TTG shall be no less than 5 μs in duration.

8.4.5.3 DL-MAP IE format

The OFDMA DL-MAP IE defines a two-dimensional allocation pattern as defined in Table 321.

</tr>
</tbody>
</table>
DIUC
DIUC used for the burst.

CID
The connection identifier that represents the assignment of the IE to a broadcast, multicast, or unicast address.

OFDMA Symbol offset
The offset of the OFDMA symbol in which the burst starts, measured in OFDMA symbols from the DL symbol in which the preamble is transmitted with the symbol immediately following the preamble being offset 1. The symbol offset shall follow the normal slot allocation within a zone so that the difference between OFDMA symbol offsets for all bursts within a zone is a multiple of the slot length in symbols.

Subchannel offset
The lowest index OFDMA subchannel used for carrying the burst, starting from subchannel 0.

Boosting
Power boost applied to the allocation’s data subcarriers. The field shall be zero in an AAS zone with AMC permutation or in a zone with AMC or PUSC-ASCA permutation using dedicated pilots.

No. OFDMA Symbols
The number of OFDMA symbols that are used (fully or partially) to carry the DL PHY burst. The value of the field shall be a multiple of the slot length in symbols.

No. of subchannels
The number of subchannels with subsequent indexes, used to carry the burst.

Repetition Coding Indication
Indicates the repetition code used inside the allocated burst. Repetition shall be used only for DIUC indicating QPSK modulation.

The subchannels offsets referred to in all formats of DL-MAP IE are logical subchannels, before subchannel renumbering in the DL.

8.4.5.3.1 DIUC allocation

Table 322 defines the DIUC encoding that shall be used in the DL-MAP IEs.

<table>
<thead>
<tr>
<th>DIUC</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–12</td>
<td>Different burst profiles</td>
</tr>
<tr>
<td>13</td>
<td>Gap/PAPR reduction</td>
</tr>
<tr>
<td>14</td>
<td>Extended-2 DIUC IE</td>
</tr>
<tr>
<td>15</td>
<td>Extended DIUC</td>
</tr>
</tbody>
</table>

DIUC = 0 shall have burst profile parameters that are the same as those used for transmission of the DL-MAP message.

DIUC = 13 may be used for allocation of Subchannels for PAPR reduction schemes. DIUC = 13 may also be used by the BS to create coverage enhancing safety zones. This is intended to provide reduced interference zones within the coverage area of the BS. The reduced interference zones are useful when the BS interfere with other BS. In such situations, the reduced interference zones may be used by the interfered BS to transmit data to SS that are registered with it, which would otherwise suffer from interference.

The SS shall ignore the received signal in the GAP/PAPR reduction region.
8.4.5.3.2 DL-MAP Extended IE format

A DL-MAP IE entry with a DIUC = 15 indicates that the IE carries special information and conforms to the structure shown in Table 323. A station shall ignore an extended IE entry with an extended DIUC value for which the station has no knowledge. In the case of a known extended DIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

8.4.5.3.2.2 DL-MAP Extended-2 IE encoding format

A DL-MAP IE entry with a DIUC = 14 indicates that the IE carries special information and conforms to the structure shown in Table 325. A station shall ignore an extended-2 IE entry with an extended-2 DIUC value for which the station has no knowledge. In the case of a known extended-2 DIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

The Unspecified Data field shall be padded with bits set to zero to get an integer number of bytes, specified by Length, in the data field of the IE.

8.4.5.3.3 AAS DL IE format

Within a frame, the switch from non-AAS to AAS-enabled traffic is marked by using the extended DIUC = 15 with the AAS_DL_IE() (see Table 329). The AAS DL IE defines a DL AAS zone that spans continuous OFDMA symbols until terminated by a Zone Switch IE, another AAS DL IE, or the end of the DL frame.
Multiple AAS zones can exist within the same frame. For the HARQ MAP, the last AAS IE is relevant until the beginning of the broadcast region if defined in the HARQ Format Configuration IE. When used, the CID in the DL-MAP_IE() shall be set to the Broadcast CID. All DL bursts in the AAS portion of the frame may be preceded by an AAS preamble based on the Downlink_Preamble_Config field in the AAS_DL_IE(). The preamble is defined in 8.4.4.7.4.1.

Permutation

Defines the permutation used within the DL AAS zone.

DL_PermBase

Permutation base for specified DL AAS zone.

OFDMA Symbol offset

The offset of the OFDMA symbol in which the AAS zone starts, measured in OFDMA symbols from beginning of the current DL frame.

Downlink_preamble_config

Defines the number of DL AAS preambles to be used before each DL burst in the AAS zone.

Following an AAS IE indicating AMC permutation, the AMC type shall be 2x3 (2 bins by 3 symbols).
Figure 236 shows the burst allocations in the DL AAS zone.

![Burst allocations in DL AAS zone](image)

### 8.4.5.3.4 STC DL Zone IE format

In the DL-MAP, a BS may transmit DIUC = 15 with the STC_DL_Zone_IE() to indicate that the subsequent allocations shall use a specific permutation and/or use a specific Tx diversity mode. The DL frame shall start in PUSC mode with no Tx diversity. Allocations subsequent to this IE shall use the permutation and Tx diversity mode it instructs, until the next STC DL Zone IE, AAS DL IE or MBS_MAP_IE with MBS permutation zone defined = 1. Allocation for a STC-capable SS shall be done through either DL_MAP_IE() or any one of the MIMO-related IEs (MIMO_DL_Basic_IE(), MIMO_DL_Enhanced_IE(), MIMO_DL_Chase_HARQ_subburst_IE, MIMO_DL_IR_HARQ_subburst_IE, MIMO_DL_IR_HARQ_for_CC_subburst_IE, or MIMO_DL_STC_HARQ_subburst_IE). If DL_MAP_IE() is used, the matrix indicator in STC_DL_Zone_IE() shall be used for the allocation with the number of individually encoded streams being 1. If any one of the MIMO-related IEs is used, the matrix indicator in these IEs shall override the matrix indicator in STC_DL_Zone_IE(). A DL zone can be a coordinated zone between the serving BS and all its neighbor BSs that has the same zone boundary, the same zone permutation type e.g., PUSC, STC PUSC, AMC, and STC AMC, and the same values for the parameters, Use All SC and Dedicated Pilots. Within a coordinated DL zone, all the allocations shall have the parameter “boosting” set to 0b000, i.e., not boosted. A frame can have zero, one, or multiple coordinated DL zones. The first PUSC zone can also be a coordinated DL zone. When the first PUSC zone is a coordinated zone, serving BS coordinates with its neighbor BSs have the same zone boundary and use the same “used-subchannel bitmap.” The format for the STC DL Zone IE is shown in Table 330.

1: Boosting (3 dB) |
| **2/3 antennas select**      | 1          | 0: STC using 2 antennas  
1: STC using 3 antennas  
Selects 2/3 antennas when STC = 0b01 |
| **Dedicated Pilots**         | 1          | 0: Pilot symbols are broadcast  
1: Pilot symbols are dedicated. An MS should use only pilots specific to its burst for channel estimation |
| **Reserved**                 | 4          | Shall be set to zero                                                 |
Permutation
Indicates the permutation that shall be used by the transmitter for allocations following this IE. Permutation changes are only allowed on a zone boundary. The IDcell indicated by the IE shall be used as the basis of the permutation (see 8.4.6.1).

Use All SC
When set, this field indicates transmission on all available subchannels. For FUSC permutation, transmission is always on all subchannels.

STC
Indicates the STC mode that shall be used by the transmitter for allocations following this IE (see 8.4.8). All allocations with STC = 0b00 shall be transmitted with non-STC pilot pattern. All allocations with STC not set to 0b00 shall be transmitted with the corresponding pilot pattern in 8.4.8. The STC mode change is allowed only on a zone boundary.

DL_PermsBase
DL Permutation base for the specified DL zone. When the zone defined by this STC_DL_Zone_IE() is a DL coordinated zone, the DL_PermsBase field shall be set to the 5 LSBs of IDcell as indicated by the frame preamble.

PRBS_ID
Values: 0..2. Refer to 8.4.9.4.1. When the zone defined by this STC_DL_Zone_IE() is a DL coordinated zone, the PRBS_ID field shall be set to mod(segment number + 1, 3) as indicated by the frame preamble.

Use All SC
Indicates if all subchannels are used. Applies to PUSC only. When set to 0, do not use all subchannels. When set to 1, use all subchannels. When the zone defined by this STC_DL_Zone_IE() is a DL coordinated zone, the Use All SC field shall be set to the same value as that in the corresponding DL coordinated zones of all its neighbor BSs.

Dedicated Pilots
When the data allocations are precoded/beamformed, then setting the Dedicated Pilots bit to 1 means the pilot symbols are precoded/beamformed in the same way as are the corresponding data subcarriers. In this case, an MS should use only the pilots that are specific to its allocation for channel estimations. In addition, a BS shall toggle CID-Switch IE() such that INC_CID = 1 in all non-HARQ DL-MAP IEs that allocate dedicated pilot zones.

For the PUSC permutation, the pilot symbols belonging to a major group shall be precoded/beamformed along with all of the data allocations made within the major group. For the FUSC or optional FUSC permutation, all of the pilot symbols and data subcarriers within an OFDM symbol shall be precoded/beamformed. The minimum time duration of any allocation in a DL STC zone with dedicated pilots is equal to the pilot period.

For backward compatibility, for the FUSC or optional FUSC permutation, multiple SS units that do not support dedicated pilots shall not be allocated in TD zones in which pilots are dedicated. However, a single legacy SS unit can be allocated to a TD zone in which the pilots are dedicated as long as no other SS units are also allocated to that TD zone. For the PUSC permutation, only a single legacy SS can be allocated to one or more major groups and only when the major groups extend across the entire zone.

Allocations with single antenna pilot pattern can coexist with allocations with multiple antennas pilot pattern in AMC STC zones with dedicated pilots. All allocations with the STC field not set to 0b00 and Dedicated Pilots set to 1 shall transmit the pilots using the pattern (see 8.4.6.1.2 for one antenna and see 8.4.8 for multiple antennas) corresponding to the number of streams instead of the actual number of transmit antennas. By default, the number of streams shall be equal to the number of antennas specified by the STC Zone Switch IE and may be overridden by the burst allocations given in the Num_Streams field of the CL_MIMO_DL_Enhanced_IE or Dedicated_MIMO_DL_Control_IE.

When the zone defined by this STC_DL_Zone_IE() is a DL coordinated zone, the Dedicated Pilots field shall be set to the same value as that in the corresponding DL coordinated zones of all its neighbor BSs.
Permutation
Indicates the permutation that shall be used by the transmitter for allocations following this IE. Permutation changes are only allowed on a zone boundary. The DL PermBase indicated by the IE shall be used as the basis of the permutation.

Midamble presence
When set, midamble shall be transmitted in the first symbol of the zone with the corresponding antenna configuration specified in the STC zone IE (see 8.4.8.5).

This IE should not be used within SUB-DL-UL-MAP.

8.4.5.3.5 Channel Measurement IE

An extended IE with an extended DIUC = 0x00 is issued by the BS to request a channel measurement report (see 6.3.15). The IE includes an 8-bit Channel Nr value as shown in Table 331.

<table>
<thead>

8.4.5.3.6 Data Location In Another BS IE

In the DL-MAP, a BS may transmit DIUC = 15 with the Data_Location_in_Another_BS_IE() to indicate that data are transmitted to the SS through another BS. This IE shall be sent right after the IE defining the same data received in the current BS, but it may be sent alone without the IE defining the same data received in the current BS only if the data are to be transmitted in the current frame.

<table>

</tbody>
</table>
### 8.4.5.3.7 CID Switch IE

In the DL-MAP, a BS may transmit DIUC = 15 with the CID-Switch_IE() to toggle the inclusion of the CID parameter in DL-MAP allocations. The DL-MAP and SUB-DL-UL-MAP shall begin in the mode where CIDs are not included. The first appearance of the CID-Switch_IE() shall toggle the DL-MAP mode to include CIDs. Any subsequent appearance of the CID-Switch_IE() shall toggle the DL-MAP CID inclusion mode.

The format for the DL CID Switch IE is shown in Table 333.

8.4.5.3.8 MIMO DL Basic IE format

In the DL-MAP, a MIMO-enabled BS may transmit DIUC = 14 with the MIMO_DL_Basic_IE() to describe DL allocations assigned to MIMO-enabled SSs. The MIMO mode indicated in the MIMO_DL_Basic_IE() shall only apply to the allocations indicated in the IE. The format for the MIMO DL Basic IE is shown in Table 334. The allowed combinations of number of antennas, matrices, number of encoded streams, and CIDs are listed in Table 335.

**Num.Region**

This field indicates the number of the regions defined by the OFDMA Symbol Offset, Subchannel Offset, Boosting, No. OFDMA Symbols, and No. Subchannels fields in this IE. The actual number of assigned regions is this field value plus 1.

**Matrix_indicator**

The values of these 2 bits indicate the STC matrix (see 8.4.8.1.4).

**Num_layer**

Number of individually encoded streams allocated in the region. The layer is defined as a separate coding/modulation path.
Layer_index
This field specifies the layer index.

Table 335 defines the modes of operation specified by MIMO_DL_Basic_IE() and MIMO_DL_Enhanced_IE(). For each information element, the table details the number of antennas (as indicated by the latest STC_DL_Zone_IE()), the type of matrix, the number of encoded streams (i.e., the number of different CIDs stated in the Num_layers “for” loop in Table 334), and the implicit type and rate of coding. The cases of either Broadcast CID or (INC_CID == 0) correspond to single CID rows, but should be decoded by all SSs on a BE basis. An SS that does not support decoding of multiple overlapping bursts shall attempt to decode the first burst relevant to it, according to the stream ordering. If Dedicated Pilots is set to 1, all references to the number of Tx antennas in this subclause apply to the number of streams.

</tbody>
</table>
Vertical encoding
Indicates transmitting a single FEC-encoded stream over multiple antennas. The number of encoded streams is always 1.

Horizontal encoding
Indicates transmitting multiple separately FEC-encoded streams over multiple antennas. The number of encoded streams is more than 1.

Rate
The number of QAM symbols signaled per array channel use.

8.4.5.3.9 MIMO DL Enhanced IE format

In the DL-MAP, a MIMO-enabled BS may transmit DIUC = 14 with the MIMO_DL_Enhanced_IE(), as shown in Table 336, to describe DL allocations assigned to MIMO-enabled SSs, each identified by the CQICH_ID previously assigned to the SS. The MIMO mode indicated in the MIMO_DL_Enhanced_IE() shall only apply to the allocations indicated in the IE. The allowed combinations of number of antennas, matrices, number of encoded streams, and CIDs are listed in Table 335.

**Num Region**

This field indicates the number of the regions defined by OFDMA Symbol Offset, Subchannel Offset, Boosting, No. OFDMA Symbols, and No. Subchannels fields in this IE. The actual number of assigned regions is this field value plus 1.

**Matrix_indicator**

The values of these 2 bits indicate the STC matrix (see 8.4.8.1.4).

**CQICH_ID**

This is the CQICH_ID assigned to an SS in the CQICH_Alloc_IE(). The CQICH_ID is used to uniquely identify an SS that is assigned a CQICH.

**Num_layers**

Number of individually encoded streams allocated in the region. The layer is defined as a separate coding/modulation path.

**Layer_index**

This field specifies the layer index.

**8.4.5.3.10 HARQ and Sub-MAP Pointer IE**

This IE shall only be used by a BS supporting HARQ of SUB-DL-MAP for MSs supporting HARQ. There shall be at most four HARQ MAP Pointer IEs in the DL-MAP. There shall be at most 3 SUB-DL-UL-MAP pointer IEs per frame, as specified in 6.3.2.3.55. Table 337 shows the format for the HARQ and Sub-MAP Pointer IE.

When the MAP message pointed by this pointer IE includes any MAP IE for an MS that is not in either sleep mode or idle mode, the bit index corresponding to $[(\text{Basic CID of the MS}) \mod n]$ in this CID Mask field shall be set to 1. Otherwise, it shall be set to 0. |

DIUC
Indicates the burst profile used for the HARQ MAP message or Sub-DL-UL-MAP message.

No. Slots
The number of OFDMA slots allocated for the burst containing a HARQ MAP message or Sub-DL-UL-MAP message. The HARQ MAP message, if any, shall immediately follow the Compressed MAP with the number of the slots allocated for the HARQ MAP message. The specification on the allocation of Sub-DL-UL-MAPs is described in 6.3.2.3.55.

Repetition Coding Indication
Indicates the repetition code used inside the allocated burst.

MAP Version
Indicates the version of the pointed MAP, that is, the HARQ MAP or Sub-DL-UL-MAP.
### 8.4.5.3.11 DL-MAP Physical Modifier IE

The Physical Modifier Information Element indicates that the subsequent allocations shall utilize a preamble, which is either cyclically delayed in time or cyclically rotated in frequency. The physical modifier type defined in this IE applies to all the subsequent allocations until terminated by a Zone_Switch_IE, AAS_DL_IE, a SUB-DL-UL-MAP or the end of the DL subframe. This IE applies to operation in AAS mode.

In the case when the preamble is cyclically delayed in time by $K$ samples, the preamble will contribute a component $s'(t)$ to the transmitted waveform as defined in Equation (59). This IE applies to operation in AAS mode.

$$s'(t) = \Re\left\{ e^{\frac{2\pi f_c t}{c}} \sum_{m=-(N_{used}^1-1)/2}^{(N_{used}^1-1)/2} c_m e^{2\pi m\Delta f(t-T_g-K/F_s)}\right\}$$  \hspace{1cm} (59)

where

- $c_m$ are the preamble tone values
- $t$ is the time, elapsed since the beginning of the OFDMA symbol, with $0 < t < T_s$

The PHYMOD DL IE can appear anywhere in the DL-MAP, and it shall remain in effect until another PHYMOD DL IE is encountered, or until the end of the DL-MAP.

In the case when the preamble is cyclically shifted in frequency, the preamble subcarriers will be shifted so that

$$C_{New,K} = (C_{Original} + 5 \times K) \mod N_{Used}$$  \hspace{1cm} (60)

where

- $C_{New,K}$ is the new subcarrier index
- $C_{Original}$ is the original subcarrier index
- $K$ is the frequency shift index indicated in the PHYMOD DL IE

The format for the DL-MAP Physical Modifier IE is shown in Table 338.

### 8.4.5.3.12 MBS MAP IE

In the DL-MAP, a BS may transmit DIUC = 14 with the MBS_MAP_IE() to indicate when the next data for a multicast and broadcast service flow will be transmitted. The offset value is associated with a CID value, and indicates the frame that the next data will be transmitted in by using the CID value. (See Table 339.) The MBS MAP message allocation parameters shall be included in the MBS MAP IE at regular intervals and if the MBS MAP message allocation parameters change. MBS MAP IE is used to specify the MBS permutation zone. When an MBS permutation zone exists in a frame, BS shall transmit MBS_MAP_IE with

</tbody>
</table>

### Preamble Modifier Type
This parameter defines whether the preamble will be cyclically shifted in time or in frequency.

### Preamble frequency shift index
This parameter effects the cyclic shift of the preamble in frequency axis, as defined by Equation (60).

### Preamble Time Shift Index
This parameter defines how many samples of cyclic shift shall be introduced into the preamble symbols. The unit of cyclic shift depends on the subchannel permutation to ensure the frequency-domain orthogonality between the different preambles in the same subchannel.
MBS permutation zone defined = 1. The MBS permutation zone shall not use Adjacent subcarrier permutation.

When a BS needs to transmit Emergency Service Message in an MBS region, the BS shall transmit an MBS_MAP_IE() with MBS permutation zone defined = 1 and Existence of Emergency Service Message = 1. If there is MBS_MAP_IE in a DL-MAP message, MS shall decode it and check whether Emergency Service Message(s) will be transmitted or not through an MBS permutation zone. If the MS supporting the CS type used for ES detects the existence of Emergency Service Message(s) in the MBS region, the MS shall decode the MBS-MAP message in order to identify the MBS data burst on which MAC PDU containing Emergency Service Message(s) will be transmitted.

</table>
MBS permutation zone defined
Specifies method of allocation and location of MBS data bursts. If this value is 1, an MBS permutation zone is defined in the frame and MBS data burst allocations occur via MBS MAP message located in the MBS permutation zone. If this value is 0, a single MBS data burst allocation is specified directly by the MBS MAP IE.

Next MBS_MAP_IE Frame Offset
The Next MBS_MAP_IE Frame Offset value is the lower 8 bits of the frame number in which the BS shall transmit the next MBS MAP IE frame.

The burst carrying MBS MAP message shall be located at the first subchannel and first OFDMA symbol of the DL permutation zone designated for the MBS zone that is specified by the MBS MAP IE. This burst shall be located in the same frame as the MBS MAP IE that specifies it. The location of this DL permutation zone designated for the MBS zone within the frame is specified by ‘OFDMA Symbol Offset’ in MBS MAP IE.

The MS should read the DL MAP for any frame in which it expects to receive MBS bursts or MBS MAP messages to capture any possible change in the location of MBS permutation zone.

8.4.5.3.13 DL PUSC Burst Allocation in Other Segment IE
In the DL-MAP, a BS may transmit DIUC = 15 with the DL_PUSC_Burst_Allocation_in_Other_Segment_IE() to indicate that data is transmitted to the MS in other segment through other BS. (See Table 340.)

8.4.5.3.14 HO Anchor Active DL MAP IE

This MAP IE is in the DL-MAP of active non-anchor BS and indicates the burst from Anchor BS. When an MS receives an HO Anchor Active DL-MAP IE on DL-MAP message from an active non-anchor BS, it can decode a data burst transmitted from Anchor BS by using the anchor preamble in HO Anchor Active DL-MAP IE. (See Table 341.)

8.4.5.3.16 HO CID Translation MAP IE

The HO burst from active non-anchor BS is indicated by the MAP IE in DL-MAP of that BS with an Active CID. The Active CID is the CID assigned by the active non-anchor BS to translate the CID given by the Anchor BS.

Because the CID is different from the anchor CID, the CID Translation MAP IE should provide translation of the Active CID into the Anchor CID. This translation IE is transmitted by Active non-anchor BS and applied on both DL and UL IEs. The translation is valid only in the current frame. (See Table 343.)

8.4.5.3.19 UL Noise and Interference Level IE format

For the open-loop power control, UL interference and noise level shall be broadcast to MSs in the given BS coverage by BS. UL interference and noise level IE broadcast the UL interference and noise level (dBm) estimated in BS. All the UL interference and noise level are quantized in 0.5 dBm steps from −150 dBm (encoded 0x00) to −22.5 dBm (encoded 0xFF). (See Table 346.)

</tbody>
</table>
The UL interference and noise level that is indicated in the latest IE shall be used if necessary. The MS that supports open loop power control shall decode the UL noise and interference level IE even if it is in closed loop power control mode and save the values for future use (i.e., BS changes the MS’s power control mode to open loop). The BS should ensure that the MS has had a chance to receive the fields required for proper power control mode change in the UL noise and interference IE by properly setting the start-frame field in the PMC-RSP message to point after the frame that contains a transmission of the noise and interference IE following the MS’s network entry (the transmission of the UL noise and interference level IE might be before the frame in which the PMC-RSP was sent). After the first reception of the UL noise and interference IE, the MS may use the same noise and interference levels until it receives updated noise and interference levels. If the MS is in open loop power control mode and receives an UL allocation before a successful reception of any noise and interference IE, the MS may transmit by using the transmission power level calculated with Equation (132), where the noise and interference levels are estimated from the last transmission power level in closed loop using the equation for the corresponding UIUC.

8.4.5.3.20 Dedicated DL Control IE

Dedicated DL Control IE contains additional control information for each subburst in the Table 350. Because each subburst may have its own control information format dependent on the MS capability, the length of the Dedicated DL Control IE is variable. (See Table 347.)

SDMA Control Info

The Dedicated DL Control IE with SDMA Control Info = 1 shall be present within the first subburst allocation of each layer of SDMA allocations (including the first layer). Each SDMA layer has its own pilot pattern (layer \( n \) uses the pilot pattern defined for antenna \( n \), see 8.4.8). When the SDMA control info is present, the OFDMA Symbol offset and Subchannel offset shall be reset to the beginning of the two dimensional data region defined in the HARQ DL MAP IE.

For allocations specified in an AAS zone with PUSC permutation, the Num SDMA Layers value shall be identical in all Dedicated DL Control IEs that describe allocations in the same major group.

8.4.5.3.20.1 Reduced CID IE

Table 348 presents the format of reduced CID. BS may use reduced CID instead of basic CID or multicast CID to reduce the size of HARQ MAP message. The type of reduced CID is determined by BS considering the range of basic CIDs of SS connected with the BS and specified by the RCID_Type field of the Format Configuration IE.

The reduced CID is composed of 1 bit of prefix and \( n \)-bits of LSB of CID of SS. The prefix is set to 1 for the Broadcast CID or Multicast Polling CID and set to 0 for basic CID. The reduced CID cannot be used instead of Transport, Primary Management, or Secondary Management CID.
Figure 237 shows the decoding of reduced CID when the RCID_Type is set to 1.

- Normal 16 bits CID

**Prefix**
- A value of one indicates that 11 bits RCID for broadcast and multicast follows the prefix. Otherwise, the n-bits RCID for basic CID follows the prefix. The value of n is determined by the RCID_Type field in Format Configuration IE.

**RCID n**
- n-bits LSB of CID
8.4.5.3.20.2 Skip IE

This IE may be sent by BS in the mandatory DL-MAP as a broadcast IE. This IE is used to indicate to mobility enabled MS (negotiated through capability exchange in REG-REQ and REG-RSP, defined in 11.7.12.1) whether to process subsequent IEs following the Skip IE. There are two modes of operation. At the beginning of each DL-MAP, the processing of IEs is always enabled. When a Skip IE is encountered, and if Mode is set to 1, the mobility enabled MS may skip the processing of all subsequent IEs in the DL-MAP. However, when a Skip IE with Mode set to 0 is encountered, the mobility enabled MS may disable the processing of subsequent IEs until the next Skip IE is encountered in the DL-MAP. When the next Skip IE with Mode set to 0 is encountered, the MS shall enable the processing of subsequent IEs. This process continues until the end of the DL-MAP. (See Table 349.)

</tr>
</tbody>
</table>
8.4.5.3.21 HARQ DL MAP IE

The following modes of HARQ shall be supported by the HARQ DL MAP IE:

a) Chase combining HARQ for all FEC types (HARQ Chase). In this mode, the burst profile is indicated by a DIUC.

b) Incremental redundancy HARQ with CTC (HARQ IR). In this mode, the burst profile is indicated by the parameters $N_{EP}, N_{SCH}$.

c) Incremental redundancy HARQ for convolutional code (HARQ CC-IR).

The IE may also be used to indicate a non-HARQ transmission when ACK disable $= 1$.

The HARQ DL MAP IE defines one or more two-dimensional data regions (a number of symbols by a number of subchannels). These allocations are further partitioned into bursts, termed subbursts, by allocating a specified number of slots to each burst. All subbursts of a data region shall only support one of the HARQ modes. The number of slots is indicated by duration or $N_{SCH}$ fields. The slots are allocated in a frequency-first order, starting from the slot with the smallest symbol number and smallest subchannel, and continuing to slots with increasing subchannel number. When the edge of the allocation is reached, the symbol number is increased by a slot duration, as depicted in Figure 238. Each subburst is separately encoded.

![Figure 238—HARQ DL allocation](image)

The enhanced feedback 6-bit channel type or mandatory feedback channel type shall be used for CQI channels allocated through any of the DL HARQ subburst IEs.

Each HARQ Map IE and subburst IE shall be nibble-aligned. When there is an if-else clause, regardless of whether the if clause or the else clause is executed, the resulting Map IE shall be nibble-aligned. When there
is a loop, nibble-alignment shall be required before the loop starts and inside the loop. (See Table 350 and Table 351.)

Group Indicator
If the Group Indicator field is not equal to the current H-FDD group index that the MS is associated with, the MS shall switch to the group index indicated by the Group Indicator field. BS can request explicit acknowledgement from MS by setting the LSB #0 of the Dedicated DL Control Indicator to 1 in this IE, in which case MS shall use the assigned CQICH channel indicated in Allocation Index field (see 8.4.4.2.1).

</tr>
</tbody>
</table>
When an MS encounters a MIMO HARQ burst allocation with Dedicated MIMO DL Control Indicator set to 1 in the current subburst IE, the information in Dedicated MIMO DL Control IE shall override the information 1) in STC DL zone IE (e.g., matrix type indication) for the current DL zone, and 2) in the previous Dedicated MIMO DL Control IE in the same subburst IE. In addition, this information is used for all following subburst allocations with Dedicated MIMO DL Control Indicator = 0 until the next occurrence of the Dedicated MIMO DL control IE in the same subburst IE.

For MIMO HARQ allocation specified in the MIMO DL Chase HARQ Subburst IE, MIMO DL IR HARQ Subburst IE, or the MIMO DL IR HARQ for CC Subburst IE, each layer shall be allocated its associated ACK channel. The number of ACK channels associated with the subburst IE may be greater than \( N_{\text{sub burst}} \).

For each multi-SS subburst (MU Indicator = 1), if the dedicated pilot bit is set to 1 in the STC Zone IE (8.4.5.3.4) for the zone in which the subburst allocations are being made, \( N_{\text{layer}} \) for this subburst selects the pilot format for the subburst by interpreting \( N_{\text{layer}} \) as the number of Tx antennas (as defined in 8.4.8), and the SS with the first RCID shall be assigned the pilot pattern corresponding to antenna 1, of 8.4.8, the second to the pilot pattern corresponding to antenna 2, and so on. (See Table 355, Table 356, and Table 357.)

</table>
When the Rectangular subburst Indication field is set, this indicates that all subburst allocations are time-first rectangular allocations that are “Duration” number of subchannels x “Number of Symbols.” When this indicator is set, the “Duration” field specified in the subburst IE indicates the number of sub-channels for each rectangular allocation. The time duration of all rectangular allocations is always “Number of Symbols” defined in the HARQ_DL_MAP_IE(). Each subburst is separately encoded. This rectangular indicator bit is only valid for AMC allocations and all allocations with dedicated pilots. When this field is clear, subbursts shall be allocated in frequency-first manner and the duration field reverts to the default operation.

This IE is used to support the STC subpacket retransmission.

### 8.4.5.3.21.1 Dedicated MIMO DL Control IE format

Dedicated DL Control IE for MIMO contains additional control information for each subburst. Because each subburst may have its own control information format dependent on the MS capability, the length of the Dedicated DL Control IE for MIMO is variable. (See Table 358.)
