Control header

Four bits are used to indicate the following control information. If the first bit is set to 1, this means that MIMO Control information follows. If the second bit is set to 1, this IE shall contain CQI control information. Other bits are reserved for future extension. CQICH Control Info=1 shall be used only if MU indicator (as defined in Table 356) equals zero.

N_layer

Specifies the number of layers contained in this burst. The layer is defined as a separate coding/modulation path.

Matrix Indicator

This field indicates MIMO matrix for the burst. For all single stream allocations with dedicated pilots (Dedicated Pilots = 1 and Num_Streams = 1), Matrix indicator field shall be set to 0b11.

Period

Informs the SS of the period of CQI reports. A CQI feedback is transmitted on the CQICH every $2^p$ frames.

Frame Offset

Informs the SS when to start transmitting reports. The SS starts reporting at the frame number which has the same 3 LSBs as the specified Frame Offset. If the current frame is specified, the SS shall start reporting in eight frames.

Duration

Indicates when the SS should stop reporting unless the CQICH allocation is refreshed beforehand. If Duration is set to 0b0000, the BS shall deallocate the CQICH. If Duration is set to 0b1111, the CQICH is allocated indefinitely and the SS should report until it receives another MAP IE with Duration set to 0b0000.

Allocation Index

Indicates position from the start of the CQICH region.

Feedback Type

Indicates the type of feedback content on the allocated CQICH from SS. Its mapping shall be

- 0b000 = Fast DL measurement/Default Feedback with antenna grouping
- 0b001 = Fast DL measurement/Default Feedback with antenna selection
- 0b010 = Fast DL measurement/Default Feedback with reduced codebook
- 0b011 = Quantized precoding weight feedback
- 0b100 = Index to precoding matrix in codebook
- 0b101 = Channel Matrix Information
- 0b110–0b111 = Reserved

8.4.5.3.22 DL HARQ ACK IE

The DL HARQ ACK IE is used by BS to send HARQ acknowledgment to UL HARQ-enabled traffic. The bit position in the bitmap is determined by the order of the HARQ-enabled UL bursts in the UL-MAP. The frame offset $j$ between the UL burst and the HARQ ACK-BITMAP is specified by “HARQ_ACK_Delay_for UL Burst” field in the DCD message. For example, when an MS transmits a HARQ-enabled burst at frame $i$ and the burst is the $n$-th HARQ-enabled burst in the MAP, the MS should receive HARQ ACK at $n$-th bit of the BITMAP which is sent by the BS at frame $(i+j)$.

The existence of this IE shall be optional.

If the HARQ ACK BITMAP is omitted, the HARQ MS should retain the transmitted HARQ burst and retransmit it when the BS request retransmission with AI_SN. This IE may only exist in the DL-MAP message or the compressed DL-MAP message. (See Table 359.)

<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Bitmap
Includes HARQ ACK information for HARQ-enabled UL bursts. The size of the BITMAP shall be equal or larger than the number of HARQ-enabled UL bursts. Each byte carries 8 ACK indications ordered from LSB (smallest index ACK channel) to MSB. An acknowledgement bit shall be 0 (ACK) if the corresponding UL packet has been successfully received; otherwise, it shall be 1 (NAK).

8.4.5.3.23 Enhanced DL MAP IE

The Enhanced DL Map IE may be used for BS to indicate to the MS the DL resource allocation based on the channel definition specified in the DL channel definition TLV in the DCD. (See Table 360.)

**Num.Region**
A field that indicates the number of the regions defined by OFDMA_Symbol_offset, Subchannel_offset, Boosting, No._OFDMA_Symbols and No._subchannels in this IE.

**Matrix_indicator**
The values of these 2 bits indicate the STC matrix (see 8.4.8).

**Antenna Grouping Index**
A field that indicates the index of the antenna grouping index.

**Antenna Selection Index**
A field that indicates the index of the selected antenna.

**Codebook Precoding Index**
A field that indicates the index of the precoding matrix in the codebook.

**Num_stream**
The value of these 2 bits plus one indicate the number of MIMO transmission streams.

**Stream_index**
A field that specifies the stream index.

| Period (p)            | 3          | A CQI feedback is transmitted on the CQI channels indexed by the (CQI Channel Index) by the SS in every 2^p frames |

Table 363—AAS SDMA DL IE format (continued)
In an AAS zone with PUSC permutation, all AAS SDMA DL IEs that define allocations in a given major group shall contain the same value for the Number of Users field. In AAS zone with PUSC, user $n$ uses the pilot pattern as defined for antenna $n$ in 8.4.8.

### 8.4.5.3.27 PUSC ASCA Allocation IE

In the DL-MAP, a BS may transmit DIUC = 15 with the PUSC_ASCA_Alloc_IE() to indicate that data is transmitted to a PUSC-ASCA supporting MS using the PUSC-ASCA permutation. (See Table 364.)

8.4.5.3.28 H-FDD Group Switch IE

In FDD, for H-FDD MS, H-FDD Group Switch IE, as shown in Table 365, may be used by the BS to signal one or more MS to switch H-FDD groups.

<table>
<thead>

</tbody>
</table>
Group Indicator

The MS shall compare the Group Indicator field to its current H-FDD group index and if the values are not identical, the MS shall switch to the group as indicated by the Group Indicator field (see 8.4.4.2.1)

CQICH Allocation Included

If the CQICH Allocation Included field is set to 1, the MS shall respond with an acknowledgement of the group change, using the assigned CQICH channel indexed by the Allocation Index (see 8.4.4.2.1)

8.4.5.3.29 Persistent HARQ DL MAP Allocation IE

Downlink persistent allocations are used by the BS to make downlink time-frequency resource assignments which repeat periodically. The logical time-frequency resource assigned using the Persistent HARQ DL MAP IE repeats at a periodic interval. For downlink persistent allocations, the BS transmits the Persistent HARQ DL MAP IE, with the mode field set to one of the following values:

- 0b0000: Persistent DL Chase HARQ
- 0b0001: Persistent DL Incremental redundancy HARQ for CTC
- 0b0010: Persistent DL Incremental redundancy HARQ for Convolutional Code
- 0b0011: Persistent MIMO DL Chase HARQ
- 0b0100: Persistent MIMO DL IR HARQ
- 0b0101: Persistent MIMO DL IR HARQ for Convolutional Code
- 0b0110: Persistent MIMO DL STC HARQ

The Persistent HARQ DL MAP IE may be used for non persistent allocations by setting the persistent flag in the subburst IE to 0.

788
Mode

Indicates the mode in this HARQ region
0b0000: Persistent DL Chase HARQ
0b0001: Persistent DL Incremental redundancy HARQ for CTC
0b0100: Persistent MIMO DL IR HARQ
0b0101: Persistent MIMO DL IR HARQ for Convolutional Code
0b0110: Persistent MIMO DL STC HARQ
0b0111 to 0b1111: Reserved

Subburst IE Length

8 Length, in nibbles, to indicate the size of the subburst IE in this HARQ mode. The MS may skip DL HARQ Subburst IE if it does not support the HARQ mode. However, the MS shall decode NACK Channel field from each DL HARQ Subburst IE to determine the UL ACK channel it shall use for its DL HARQ burst

Table 366—Persistent HARQ DL MAP allocation IE (continued)
Persistent Region ID
The identifier of specific Persistent HARQ region. The operation commanded by the IE is applied to subbursts in the region.

Change Indicator
The change indicator can be set to 0 or 1. It is used by MSs to decide if they can resume using their DL persistent allocations. See 6.3.26.4.5 for details.

<td>—</td>
</tr>
<tr>
<td>Dedicated DL control IE()</td>
<td>variable</td>
<td>—</td>
</tr>
<tr>
<td>}</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>
The allocation flag shall be set to 1 if the subburst IE is allocating time-frequency resources and shall be set to 0 if the subburst IE is de-allocating resources.

**Resource Shifting Indicator**

If the resource shifting indicator is set to ‘1’, the MS shall shift its persistent resource position by the accumulated slots as indicated by de-allocation commands with slot offsets smaller than its own.

**Retransmission Flag**

The Retransmission Flag shall be set to 0 if the de-allocation occurs in \( K \), where \( K \) is the current frame and shall be set to 1 if the de-allocation occurred in frame \( K - \text{allocation period} \). The MS, who correctly received the DL-MAP in frame \( K - \text{allocation period} \), shall ignore the deallocation command with Retransmission Flag equal to 1. The MS, who failed to receive the DL-MAP in frame \( K - \text{allocation period} \), shall process the deallocation command with Retransmission Flag equal to 1.

The BS is allowed to retransmit de-allocation commands with the retransmission flag not set. This may cause the MS to receive a duplicated de-allocation command. The MS shall ignore a de-allocation command for which it does not have a corresponding persistent resource allocation.

**Persistent Flag**

The persistent flag shall be set to 1 if the assignment is persistent and shall be set to 0 if the assignment is non-persistent.

**Slot Offset**

The slot offset shall be set to the first slot in the time-frequency resource assignment with respect to the lowest numbered OFDM symbol and the lowest numbered subchannel in the HARQ region.

**Duration Indicator**

Duration Indicator flag determines whether or not Duration is specified for a subburst. If this flag is 1, it indicates that Duration is explicitly assigned for a subburst. Otherwise, the subburst has the same Duration as the previous subburst. This flag shall be 1 for the first subburst in a HARQ region.

**Duration**

Duration specifies the size (# slots) of an allocation/de-allocation in a HARQ region.

**Allocation Period and N_ACID Indicator**

If Allocation Period and N_ACID Indicator is 1, it indicates that allocation period and Number of ACID (N_ACID) is explicitly assigned for this subburst. Otherwise, this subburst will use the same allocation period and N_ACID as the previous subburst. This flag shall be 1 for the first subburst in a HARQ region.

**Allocation Period**

The allocation period value shall be set to \((ap-1)\) where \( ap \) is the period of the persistent allocation, in units of frames. For example, as illustrated in Figure 239, if \( ap=0b00011 \), then the period of the persistent allocation is four frames, and the time-frequency resource assignment is valid in frames \( N, N+4, N+8 \), etc.

---

<th>Size (bit)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Padding</td>
<td>variable</td>
<td>Padding to nibble; shall be set to 0</td>
</tr>
</tbody>
</table>

---
The values of ACID field (N0) and N_ACID field (N) are used together to specify an implicit cycling of HARQ channel identifiers as follows. N0 is used as the HARQ channel identifier corresponding to the first occurrence of the persistent allocation. For each next allocation this value is incremented modulo (N + 1).

As illustrated in Figure 240, if N_ACID = 0b011 (meaning Num_HARQ_Chan = 4), and if ACID = 2, the HARQ channel identifier follows the pattern 2, 3, 4, 5, 2, 3, 4, 5, etc.

**ACID**

The ACID field shall be set to the initial value of HARQ channel identifier as described above.

**AI_SN**

The AI_SN field value shall be set to the initial ARQ identifier sequence number for each HARQ channel. The AI_SN toggles between 0 and 1 for each particular HARQ channel. For example, if the period equals 4 frames, N_ACID = 0b011, ACID = 2, and AI_SN = 0, the ACID follows the pattern 2, 3, 4, 5, 2, 3, 4, 5, etc, and the AI_SN follows the pattern 0, 0, 0, 0, 1, 1, 1, 1, etc.

**ACK channel**

The ACK channel field shall be set to the number of the ACK channel within the HARQ ACK Region. The mobile station shall use the indicated ACK channel for transmitting acknowledgment information for each packet received using the time-frequency resource referred to by this persistent allocation.

**MAP NACK Channel Index**

The MAP NACK channel index is persistently allocated within the Fast Feedback region. The mobile station shall use the indicated MAP NACK channel to report MAP decoding error in frames where it has a persistent resource allocation assigned. When MAP NACK Channel Index = 0b111111, it indicates NO MAP NACK channel is assigned to this allocation.

**MAP ACK Channel Index**

The MAP ACK channel is allocated non-persistently within the Fast Feedback region. The mobile station shall use the indicated MAP ACK channel to report successful receipt of the persistent allocation IE. If the allocation flag is set to 0, when MAP ACK Channel Index = 0b111111, it indicates NO MAP ACK channel is assigned to this deallocation.

8.4.5.3.30 Power Boosting IE

In the DL-MAP, BS may transmit the Power Boosting IE, as shown in Table 374, to signal the update of power boosting information for persistent allocations assigned to MSs by the Persistent HARQ DL MAP IE.
The power boosting information in the Power Boosting IE shall be applied to persistent allocation associated with the R_CID and ACID in the Power Boosting IE.

8.4.5.4 UL-MAP IE format

The OFDMA UL-MAP IE defines UL bandwidth allocations. UL bandwidth allocations are specified either as block allocations (subchannel by symbol) with an absolute offset or as an allocation with duration in slots with either a relative or absolute slot offset. Block allocations are used for fast feedback (UIUC = 0), HARQ ACK CH region (UIUC-11 (Extended-2 UIUC) with Type = 8), CDMA ranging and BR allocations (UIUC = 12) as well as PAPR/safety zone allocations (UIUC = 13). Slot allocations are used for all other UL bandwidth allocations. For UL allocations in non-AAS zones, the starting position for the allocation is determined considering the prior allocations appearing in the UL-MAP. For UL allocations in an AAS UL zone, the starting position is included in the UL IE indicating an absolute slot offset from the beginning of the AAS zone. If an OFDMA UL-MAP IE with UIUC = 0 or UIUC = 11, (Extended-2) with Type = 8 or UIUC = 12 or UIUC = 13 exists, it shall always be allocated first. In FDD/H-FDD, if uplink allocation is made for FDD MSs in the other UL Group (that is, the UL Group different from the UL-MAP belongs to), OFDMA UL-MAP IE with UIUC 11 with Type = 13 shall be used to notify that allocation.

For the first OFDMA UL-MAP IE with UIUC other than 0, UIUC = 11 (Extended-2) with Type = 8, UIUC = 12, or UIUC = 13, the allocation shall start at the lowest numbered nonallocated subchannel on the first nonallocated OFDMA symbol defined by the Allocation Start Time field of the UL-MAP message that is not allocated with UIUC = 0 or UIUC = 11 (Extended-2) with Type = 8 or UIUC = 12 or UIUC = 13 (see Figure 221 for an example). These IEs shall represent the number of slots provided for the allocation. For allocations not in an AAS zone, each allocation IE shall start immediately following the previous allocation and shall advance in the time axis. If the end of the UL zone has been reached, the allocation shall continue at the next subchannel at first OFDMA symbol allocated to that zone that is not allocated with UIUC = 0 or UIUC = 11 (Extended-2) with Type = 8 or UIUC = 12 or UIUC = 13. A UIUC shall be used to define the type of UL access and the burst type associated with that access. A burst descriptor shall be specified in the UCD for each UIUC to be used in the UL-MAP. For further details on allocations in an UL AAS zone, see 8.4.4.7.
The format of the UL-MAP IE is defined in Table 376.

</tbody>
</table>
CID
The CID shall be the SS’s Basic CID for UIUC 1–10, 11 or 15, when appropriate, and the broadcast or multicast CID for UIUC 0 and 11–15.

UIUC
UIUC used for the burst.

OFDMA symbol offset
The offset of the OFDMA symbol in which the burst starts, the offset value is defined in units of OFDMA symbols and is relevant to the Allocation Start Time field given in the UL-MAP message.

Subchannel offset
The lowest index subchannel used for carrying the burst, starting from subchannel 0.

No. OFDMA symbols
The number of OFDMA symbols that are used to carry the UL burst.

No. subchannels
The number of subchannels with subsequent indices.

Duration
Indicates the duration, in units of OFDMA slots, of the allocation.

Repetition coding indication
Indicates the repetition code used inside the allocated burst. Repetition shall be used only for UIUC indicating QPSK modulation.

When a ranging region (UIUC = 12) is present in the UL subframe, and the SS is in ranging backoff state, it shall count the ranging opportunities present in the ranging region. Only ranging allocations allocated in permutation zones supported by the SS and matching the type of backoff the SS (ranging or BR) shall be considered as containing relevant ranging opportunities.

The subchannel offsets in all formats of UL-MAP IE are referred to logical subchannels before applying the mapping indicated by UL subchannel’s bitmap in UCD and rotation scheme (see 8.4.6.2.6) for the UL.

For SUB-UL-DL-MAPs, the current UL zone is automatically reset to the UL zone containing the OFDMA symbol whose offset is specified in the SUB-DL-UL-MAP. The current UL zone is thereafter updated whenever an UL-MAP IE contains an explicit OFDMA symbol offset.
Some control regions may be defined in UCD via FastFeedback Region TLV, HARQ ACK Region TLV, Ranging Region TLV and Sounding Region TLV. These control regions include:

- Initial/HO ranging region, Periodic Ranging/BW request region (UIUC = 12)
- FastFeedback region (UIUC = 0)
- DL HARQ ACK region (UIUC = 11 (Extended 2 UIUC with Type = 8))
- UL Sounding region (UIUC = 13 with Sounding Zone bit = 1)

These UCD TLVs specify a data region within UL subframe and frame numbers of UL MAP where the corresponding control region IE would appear, however when such a control region is specified by a UCD TLV, the corresponding control region IE does not need to appear in the UL MAP. The frame numbers of UL MAP are described by periodicity and phase so that MS can identify the numbers as sum of phase and integer multiples of periodicity. The actual UL subframes where MS transmit UL signals are further delayed by UL Allocation Start Time of UL MAP.

If certain TLV is present in UCD messages with certain value of the Configuration Change Count, the corresponding allocation shall be valid in all UL subframes specified by UL MAP messages with the same value of Configuration Change Count.

If UL MAP allocates one or more of the regions defined via UIUC=0, UIUC=11 (extended 2 UIUC with type=8), UIUC=12 or UIUC=13, these UIUC allocations override the corresponding allocations of the periodic regions defined by UCD in the specific frame.

### 8.4.5.4.1 UIUC allocation

Table 377 defines the UIUC encoding that shall be used in the UL-MAP_IE().

<table>
<thead>
<tr>
<th>UIUC</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>PAPR reduction allocation, safety zone, Sounding Zone</td>
</tr>
<tr>
<td>14</td>
<td>CDMA Allocation IE</td>
</tr>
<tr>
<td>15</td>
<td>Extended UIUC</td>
</tr>
</tbody>
</table>

The UIUC = 0 is used for allocation of fast-feedback channel region. There shall not be more than one UL-MAP IE with UIUC = 0 for a UL frame. The UIUC = 13 is used for allocation of Subchannels for PAPR reduction schemes. The data subcarriers within these subchannels may be used by all SSs to reduce PAPR of their transmissions. Alternatively, it can also be used by the BS to create coverage enhancing safety zones for UL. This is intended to provide reduced interference zones within the coverage area of the SS. The reduced interference zones are useful when the SS in the neighboring BS are near the cell edge and interfering with SS in the current BS. In such situations, the reduced interference zones may be used by the SS in the neighboring BS so that the SS in the current BS do not suffer from interference.
The CDMA allocation UIUC provides (among other things) a function similar to the initial ranging UIUC used in other PHY options; therefore, instructions that relate to messages transmitted in the initial ranging UIUC shall apply to messages transmitted in the CDMA allocation UIUC as well.

### 8.4.5.4.2 PAPR Reduction/Safety Zone/Sounding Zone Allocation IE

Table 378 defines the PAPR Reduction/Sounding Zone/Safety Zone Allocation IE. This IE is identified by UIUC = 13. When a UIUC 13 allocation is used to define a Sounding Zone, it shall occupy one or more entire OFDMA symbol(s) and be located in the last symbol(s) of a permutation zone.

#### Table 378—PAPR Reduction/Safety Zone/Sounding Zone Allocation IE format

</tbody>
</table>

**OFDMA symbol offset**

The offset of the OFDMA symbol in which the PAPR reduction/safety zone starts. The offset value is defined in units of OFDMA symbols and is relevant to the Allocation Start Time field given in the UL-MAP message.

**Subchannel offset**

The lowest index subchannel that is used for the PAPR reduction/safety zone, starting from subchannel 0. For Sounding Zone allocations this field is unused and its value shall be set to zero.

**No. OFDMA symbols**

The number of OFDMA symbols that are used for the UL PAPR reduction/safety zone.

**Number of subchannels/SZ Shift Value**

The number of subchannels with subsequent indexes that are used for the PAPR reduction/safety zone. For Sounding Zone allocations this field defines the shift value (u) used for decimation offset and cyclic shift index.

### 8.4.5.4.3 CDMA Allocation UL-MAP IE format

Table 379 defines the UL-MAP IE for allocation of bandwidth to a user that requested bandwidth using a CDMA request code. This IE is identified by UIUC =14.

**Repetition coding indication**
Indicates the repetition code used inside the allocated burst.

**Frame Number Index**
Identifies the frame in which the CDMA code to which this message responds was transmitted. The 4 LSBs of the frame number are used as the frame number index.

**Ranging Code**
Indicates the CDMA code sent by the SS.

**Ranging Symbol**
Indicates the OFDMA symbol used by the SS.

**Ranging subchannel**
Identifies the ranging subchannel used by the SS to send the CDMA code.

**BW request mandatory**
Indicates whether the SS shall include a BR in the allocation.

### 8.4.5.4.4 UL-MAP Extended IE

#### 8.4.5.4.4.1 UL-MAP Extended IE format

A UL-MAP IE entry with a UIUC = 15 indicates that the IE carries special information and conforms to the structure shown in Table 380. A station shall ignore an extended IE entry with an extended UIUC value for which the station has no knowledge. In the case of a known extended UIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

Table 381 defined the encoding for extended UIUC that shall be used by UL-MAP Extended IEs.
8.4.5.4.4.2 UL-MAP Extended-2 IE format

A UL-MAP IE entry with a UIUC = 11 indicates that the IE carries special information and conforms to the structure shown in Table 382. A station shall ignore an Extended-2 IE entry with an extended-2 UIUC value for which the station has no knowledge. In the case of a known extended-2 UIUC value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

The Unspecified Data field shall be padded with bits set to zero to get an integer number of bytes, specified by Length, in the data field of the IE.

8.4.5.4.4.3 UL-MAP Extended-3 IE format

A UL-MAP IE entry with an Extended-2 UIUC = 0x5 indicates that the IE carries special information and conforms to the structure shown in Table 384. A station shall ignore an Extended-3 IE entry with an extended-3 UIUC value for which the station has no knowledge. In the case of a known extended-3 UIUC
value but with a length field longer than expected, the station shall process information up to the known length and ignore the remainder of the IE.

The Unspecified Data field shall be padded with bits set to zero to get an integer number of bytes, specified by Length, in the data field of the IE.

**8.4.5.4.5 Power Control IE format**

When a power change for the SS is needed, the extended UIUC = 15 may be used with the subcode 0x00 and with 8-bit power control value as shown in Table 386. The power control value is an 8-bit signed integer expressing the change in power level (in 0.25 dB units) that the SS should apply to correct its current transmission power.

The CID used in the IE should be the Basic CID of the SS.

**Table 386—OFDMA Power Control IE**

### Power measurement frame

The 8 LSB of the frame number in which the BS measured the power corrections referred to in the message.

#### 8.4.5.4.6 AAS UL IE format

Within a frame, the switch from non-AAS to AAS-enabled traffic is marked by using the extended UIUC = 15 with the AAS_UL_IE() to indicate that the subsequent allocation shall be for AAS traffic. The AAS UL IE defines a UL AAS zone that spans continuous OFDMA symbols of length defined by the AAS zone Length field. Multiple UL AAS zones can exist within the same frame. When used, the CID in the UL-MAP_IE() shall be set to the Broadcast CID. All UL bursts in the AAS portion of the frame may be preceded by an AAS preamble based on the indication in the AAS_UL_IE(). The preamble is defined in 8.4.4.7.4.2. Table 387 shows the format for the AAS UL IE.

</tr>
</tbody>
</table>
**Permutation**
Defines the permutation used within the UL AAS zone.

**UL_PermBase**
Permutation base for specified UL AAS zone.

**OFDMA Symbol offset**
The symbol offset of the UL AAS zone. This is referenced to the Allocation Start Time field in the UL-MAP.

**Uplink_preamble_config**
Defines the number of UL AAS preambles to be used before each UL burst in the AAS zone.

Following an AAS IE indicating AMC permutation, the AMC type shall be 2x3 (2 bins by 3 symbols).

### 8.4.5.4.7 UL Zone Switch IE format

In the UL-MAP, a BS may transmit UIUC = 15 with the UL_Zone_IE() to indicate that the subsequent allocations shall use a specific permutation. A UL_Zone_IE() may appear ahead of all UL Allocation IEs and indicate the permutation of the first and the following slots. If a UL_Zone_IE() does not appear ahead of all UL Allocation IEs, the UL frame shall start in PUSC mode with UL_PermBase as indicated in the UCD message. Allocations subsequent to this IE shall use the permutation it instructs. No burst allocation or ranging channel allocation shall span multiple zones. Table 388 shows the format for a UL Zone IE.

In FDD/H-FDD, the UL Zone Switch IE can be included in the FDD_Paired_Allocation_IE(). If the UL Zone Switch IE is included in the FDD_Paired_Allocation_IE(), it indicates the configuration of the uplink zone in the other UL Group (that is, the UL Group different from the UL-MAP belongs to). UL-MAP IEs following the UL Zone Switch IE included in the FDD_Paired_Allocation_IE() shall indicate uplink allocations made in the other UL Group. If the zone permutation of the last uplink zone in the first subframe (UL Group2) and that of the first uplink zone in the second subframe (UL Group1) are the same, BS may enable uplink burst allocation made over two consecutive subframes in the same frame by setting H-FDD Over_subframe Allocation = 1. If the gap in-between two uplink subframes (UL_gap) is multiple of uplink slot duration, BS may set H-FDD Inter-UL_gap Allocation = 1 for the last uplink zone in UL Group2 to indicate F-FDD MS that the uplink allocation shall be made up to the slots in the UL_gap.

</tbody>
</table>
OFDMA symbol offset
The offset of the OFDMA symbol in which the zone starts, the offset value is defined in units of OFDMA symbols and is relevant to the Allocation Start Time field given in the UL-MAP message.

Permutation
Indicates the permutation that shall be used by the transmitter for allocations following this IE. Permutation changes are only allowed on a zone boundary. The UL_PermBase indicated by the IE shall be used as the basis of the permutation (see 8.4.6.2.2 and 8.4.6.2.3).

Use All SC indicator
When the Use All SC indicator bit is set to 0, subchannels indicated by the allocated subchannel bitmap in UCD shall be used. Otherwise, all subchannels shall be used. This field shall be ignored in zones other than PUSC and O-PUSC.

This IE should not be used within SUB-DL-UL-MAP.
8.4.5.4.8 Mini-Subchannel Allocation IE

The Mini-Subchannel Allocation IE is used for subdividing subchannels into mini-subchannels. This IE uses the extended UIUC = 15 with the subcode 0x01 with the structure shown in Table 389. The CID in the UL-MAP when using the mini-subchannel allocation IE shall be set to the Broadcast CID.

Table 389—Mini-Subchannel Allocation IE format

</tr>
</tbody>
</table>

**Ctype**
- Defines M, the number of mini-subchannels allocated by this IE.

**Duration**
- Defines the allocation duration in OFDMA slots. The duration shall be an integer multiple of M.

**CID(j)**
- CID to use for mini-subchannel with index j.

**UIUC(j)**
- UIUC to use for mini-subchannel with index j. Allowed values are 1–10.

**Repetition(j)**
- Indicates the repetition code used inside the allocated burst for mini-subchannel with index j.
8.4.5.4.9 Fast-Feedback Allocation IE

The Fast-feedback Allocation IE is used to specify allocations for the fast-feedback slots. Fast-feedback slots are mapped to the region marked by UIUC = 0 in the UL-MAP, in a frequency-first order, as shown in Figure 241.

Figure 241—Mapping order of fast-feedback messages to the fast-feedback region

The fast-feedback region shall be allocated using the Fast-Feedback Allocation IE as defined in Table 390.

Table 390—Fast-Feedback Allocation IE format

</tbody>
</table>
8.4.5.4.10 MIMO UL Basic IE format

In the UL-MAP, a MIMO-enabled BS may transmit UIUC = 15 with the MIMO_UL_Basic_IE() to indicate the MIMO mode of the UL allocations described in this IE (see Table 391). The MIMO mode indicated in the MIMO_UL_Basic_IE() shall only apply to the UL allocation within the IE. This IE may be used either for a MIMO-enabled SS or for an SS that supports only collaborative SM. The IE may also be used to assign allocations in AAS zones to AAS-enabled SSs that are capable of collaborative SM.

Table 391—MIMO UL Basic IE format

</tbody>
</table>
Num_assign
This field specifies the number of assignments in this IE. The actual number of assigned bursts is this field value plus 1.

MIMO_Control
MIMO_Control field specifies the MIMO mode of the corresponding UL burst.

Table 392 summarizes the modes of operation specified by MIMO_UL_Basic_IE(). For each mode, it details the following:

- Number of antennas
- Values of Collaborative_SM_indication and MIMO_control
- Number of different CIDs stated in the appropriate case of the “if” statement
- Implicit type and rate of coding

Table 392—MIMO UL Basic IE operation modes

</tbody>
</table>
Vertical coding
Indicates transmitting the same coded stream over multiple antennas.

Rate
The number of QAM symbols signaled per array channel use.

8.4.5.4.11 CQICH Allocation IE Format

CQICH_Alloc_IE() is introduced to dynamically allocate or deallocate a CQICH to an SS. Once allocated, the SS transmits channel quality information on the assigned CQICH on subsequent frames until the SS receives a CQICH_Alloc_IE() to deallocate the assigned CQICH or until the MS receives a sleep control message (MOB_SLP-RSP, RNG-RSP or DL sleep control extended subheader) with Stop_CQI_Allocation_Flag = 1. It is up to BS to decide whether CQI reported in sleep mode can be of use. Capability of using Stop_CQI_Allocation_Flag for de-allocating CQI channel is optional for the BS. An MS in sleep mode (during the unavailability interval) shall not transmit on the assigned CQICH. If, while in sleep (with traffic triggered wakening flag = 1), the MS transmits a bandwidth request with respect to a connection belonging to the Power Saving Class, the MS shall continue to transmit on the CQI allocated to it. An MS in sleep mode during the availability interval shall continue to transmit on the CQICH slots allocated to the MS. An example is given in Figure 242.

Figure 242—CQI transmissions during sleep mode

While in the scanning interval, an MS may transmit its allocated CQICH slots (see Table 393).

Table 393—CQICH Allocation IE format

</tbody>
</table>
The SS starts reporting at the frame of which the number has the same 3 LSB as the specified frame offset. If the current frame is specified, the SS should start reporting in eight frames. Channel Quality Information reported by a MS in Frame \( n \) pertains to measurements collected in previous frames up to and including Frame \( n-1 \), but excluding Frame \( n \). The first CQICH report following the CQICH allocation IE may contain invalid CQI data if the CQICH report is sent in the frame immediately following the frame in which the CQICH allocation IE was received.

A CQI feedback is transmitted on the CQI channels for \( 10 \times 2^d \) frames. If \( d = 0 \), the CQI-CH is deallocated. If \( d = 0b111 \), the SS should report until the BS command for the SS to stop.

Update to CINR report configuration is included.

</table>
CQICH_ID

The CQICH_ID identifies the combination of fast feedback channel, Report Configuration and MIMO Permutation Feedback Cycle created by this IE.

Period(p), Frame offset, and Duration(d)

If the MS received the CQICH_Alloc_IE in frame #N, the MS should transmit periodic reports in every 2^p frames starting from frame #M_{first} to frame #M_{last}, where #M_{first} is the first frame number (excluding frame #N) with the 3 LSB equal to the 3 bits in Frame offset and where

#M_{last} = (#M_{first} + 10 \times 2^d - 1) \mod 2^{24}.

Report configuration included

Indicates whether an update to the report configuration exists in the IE. A value of 0 indicates that the SS shall use the configuration defined in the last received CQICH_Alloc_IE with the same CQICH_ID.

Report type

Indicates whether the CINR metric shall be reported on the preamble (0) or on a permutation zone (1).

Averaging parameter included

Indicate whether a new averaging parameter \( \alpha_{avg} \) for physical CINR reports exists in the IE. A value of 0 indicates that the SS shall perform physical CINR measurements using the last known averaging parameter.

MIMO_permutation_feedback_cycle

This field specifies the MIMO and permutation mode fast-feedback cycle. See 8.4.11.3 for fast-feedback channel payload encoding for MIMO and permutation feedback. When MIMO_permutation_feedback_cycle is not equal to 0b00, the MIMO and permutation mode indication shall transmitted at certain CQICH frames instead of the normal CQI value.
For MIMO-capable SSs, the BS may allocate one or multiple CQICH channels to the SS in UL_MAP. If one CQICH channel is allocated, the SS shall report the average post-processing SNR. If multiple CQICH channels are allocated, the SS shall report post-processing SNR of individual layers, and the order of CQICH channel allocation shall match the order of layer index.

8.4.5.4.12 UL-MAP Physical Modifier IE

For an SS that supports the AAS option (see 8.4.4.7), the Physical Modifier IE indicates that the subsequent allocations shall utilize a preamble, which is either cyclically rotated in frequency or cyclically delayed [see Equation (59) and Equation (60)]. The PHYMOD UL IE can appear anywhere in the UL map, and it shall remain in effect until another PHYMOD UL IE, a Zone-Switch-IE, AAS-UL-IE or SUB-DL-UL-MAP is encountered, or until the end of the UL map. When BS schedules more than one UL transmission for an SS it shall guarantee that the preamble modifier is the same for all UL bursts of the SS (see Table 524).

</tbody>
</table>
Preamble Modifier Type

This parameter defines whether the preamble will be cyclically shifted in time or in frequency.

Preamble frequency shift index

This parameter effects the cyclic shift of the preamble in frequency axis, as defined by Equation (60).

Preamble Time Shift Index

This parameter defines how many samples of cyclic shift shall be introduced into the preamble symbols. The unit of cyclic shift depends on the subchannel permutation to ensure the frequency-domain orthogonality between the different preambles in the same subchannel.

8.4.5.4.13 UL Allocation Start IE

The UL Allocation Start IE indicates the start offset of all subsequent UL allocation including allocation done by UL-MAP IE and extended UL-MAP IE. When this IE is included in UL-MAP or SUB-DL-UL-MAP, an SS shall determine all subsequent UL allocations based on the start offset defined in this IE except when the UL allocation already specified a start offset. This IE shall be supported by all SS. (See Table 395.)

If H-FDD UL Subframe Indicator is set to '0', the UL Allocation Start IE indicates the starting offset in the UL subframe (Group) that the UL-MAP including this UL Allocation Start IE is associated with. BS shall not use UL Allocation Start IE with H-FDD UL Subframe Indicator = 1 to an MS without capability of Full-Duplex (FDD), which is negotiated using SBC-REQ/RSP.

For FDD/H-FDD, if the UL Allocation Start IE with H-FDD UL Subframe Indicator = 1 is included in the FDD_Paired_Allocation_IE(), the UL Allocation Start IE indicates the starting offset in the other UL subframe (Group) in the same frame, that is, the starting offset in the other H-FDD UL Group; namely, the one not associated with the UL-MAP in which the current UL Allocation Start IE is included.

Shall be set to zero for TDD and H-FDD only MS in FDD/H-FDD. |

### 8.4.5.4.14 CQICH Enhanced Allocation IE format

CQICH_Enhanced_Alloc_IE() is introduced to dynamically allocate or deallocate a CQICH to an SS. This IE shall only be used with enhanced fast-feedback channel in 8.4.11.4 and primary/secondary fast-feedback channel in 8.4.11.12. Once allocated, the SS transmit feedback information of the specified type on the assigned CQICH with the determined period, until the SS receives a CQICH_Enhanced_Alloc_IE() to deallocate the assigned CQICH. (See Table 396.)

</tr>
</tbody>
</table>
Frame offset
The SS starts reporting at the frame of which the number has the same 3 LSB as the specified frame offset. If the current frame is specified, the SS should start reporting in eight frames.
Information reported by an SS in Frame  is a pertains to measurements collected in previous frames up to and including Frame  but excluding Frame  .
The first CQICH report following the CQICH Enhanced allocation IE may contain invalid data if the report is sent in the frame immediately following the frame in which the CQICH Enhanced allocation IE was received.
Duration (=d)
A CQI feedback is transmitted on the CQI channels for  frames.
If  == 0b000, the CQICH is deallocated.
If  == 0b111, the MS should report until the BS command for the MS to stop.
CQICH_Num
Number of CQICHs assigned to this CQICH_ID is (CQICH_Num +1) for  .
for (i = 0; i < CQICH_Num+1; i++) {
  Feedback Type
  0b000–0b010: Fast DL measurement/Default Feedback depending on CQICH types

  CQICH Type
  0b000: 6-bit CQI
  0b001: 18-bit CQI
  0b010: 3-bit CQI (even)
  0b011: 3-bit CQI (odd)
  0b100: 6-bit CQI (primary)
  0b101: 10-bit CQI (primary + secondary)
  0b110: 6-bit CQI (even)
  0b111: 6-bit CQI (odd)
  STTD indication
  This field is only valid for CQICH Type = 0b000.
  0 – CQICH is transmitted using normal 6 bit format
  1 – CQICH is transmitted using STTD in PUSC (see Figure 263) }
Feedback Type

For CQICH type = 0b000, 0b001 or 0b100:
- 0b000 = Fast DL measurement/Default Feedback with antenna grouping
- 0b001 = Fast DL measurement/Default Feedback with antenna selection
- 0b010 = Fast DL measurement/Default Feedback with reduced codebook

When the MS transmits the feedback of S/N using 5 LSBs of 6 bits on it assigned CQICH, the MSB is set to 0 (see 8.4.11.5). MS may transmit, on its assigned CQICH, the feedback information specified in 8.4.11.7.

For CQICH type = 0b010 or 0b011:
- 0b000 = Antenna grouping (see Table 525 of 8.4.11.7)
- 0b001 = Antenna selection (see Table 526 of 8.4.11.7)
- 0b010 = Reduced codebook (see Table 527 of 8.4.11.7)

For CQICH type = 0b101:
- 0b000 = Fast DL measurement (see 8.4.11.1 and 8.4.11.5)
- 0b001 = Default Feedback with antenna grouping (see Table 518 of 8.4.11.3)
- 0b010 = Antenna selection and reduced codebook (see Table 519 of 8.4.11.3)
- 0b011 = Quantized precoding weight feedback (see Figure 297 of 8.4.11.2)

When Feedback type = 0b100 and CQICH type = 0b101, primary CQICH is assigned for index to precoding matrix in codebook while secondary CQICH is assigned for CINR.

When Feedback type = 0b110 and CQICH type = 0b101, 10 bits CQI consists of primary CQICH(6 bits) and Secondary CQICH(4 bits) from MSB to LSB. The first bit of MSB is '0' if MS transmits 6 bit PMI or '1' if MS transmits 3 bit PMI. The remaining 9 bits indicate the below information.

If MS transmits 6 bit PMI, 6 bit PMI + 1 bit differential CINR per band for the 3 best bands (from MSB to LSB).
If MS transmits 3 bit PMI, 3 bit PMI + 1 bit differential CINR per band for the 3 best bands + 3 bits (set to zero) (from MSB to LSB).

When Feedback type = 0b100 and CQICH Type = 0b001 (18 bit CQI), MS feeds back for all 3 bands in the band bitmap in the order of lowest numbered band to highest.
When Feedback type = 0b110 and CQICH Type = 0b001 (18 bit CQI), 2 bands are fed back (Nr_Precoders_feedback = 2). The first group of 6 bits carries the lowest AMC band 6-bit PMI, the second group of 6 bits carries the second AMC band 6-bit PMI, and the third group of 6 bits carries the 2-bit CINR of the 2 AMC band.

For Feedback type = 0b110 (index to precoding matrix in codebook), mapping into each group of 6 bits (CQICH types 0b000, 0b100, 0b110 or 0b111):

- 3 bit PMI mapped to MSB plus 1 bit RI plus 2 bit differential CINR as LSB

Mapping of the 2 bit differential CINR is as follows:

| 00 | -3 dB |
| 01 | -1 dB |
| 10 |  1 dB |
| 11 |  3 dB |

where

- PMI is precoding matrix index
- RI is rank information

8.4.5.4.15 UL PUSC Burst Allocation in Other Segment IE

In the UL-MAP, a BS may transmit UIUC = 15 with the UL_PUSC_Burst_Allocation_in_Other_Segment_IE() to define UL bandwidth allocation in other segment. (See Table 397.)

<table>

Num_Assign
A field that specifies the number of assignments in this IE. The actual number of assigned bursts is this field value plus 1.

Matrix_Indicator
A field that specifies the MIMO mode of UL burst. For MS with dual antenna it indicates STC Matrix and for MS with single antenna it is skipped.

Pilot Pattern Indicator
A field that indicates pilot patterns to MS with single antenna or to MS with dual antenna (see 8.4.8.1.5).

8.4.5.4.19 OFDMA Fast Ranging IE format

A Fast Ranging IE may be placed in the UL-MAP message by a BS to provide a non-contention-based initial ranging opportunity. The Fast Ranging IE shall be placed in the extended UIUC within a UL-MAP IE.
The format of the IE is PHY dependent as shown in Table 401.

- **UIUC**
  - UIUC used for the burst.
- **Duration**
  - Indicates the duration, in units of OFDMA slots, of the allocation.
- **Repetition coding indication**
  - Indicates the repetition code used inside the allocated burst.
- **HO ID indicator**
  - An indicator to indicate whether HO ID or MAC Address is being used to identify an MS during HO.
- **HO ID**
  - An identifier assigned to an MS for use during initial ranging to the selected target BS.

### 8.4.5.4.20 UL-MAP Fast Tracking IE

In the UL-MAP, a BS may transmit UIUC = 15 with the UL-MAP_Fast_Tracking_IE() to provide fast power, time and frequency indications/corrections to MSs that have transmitted in the frame before the previous frame.
The CID used in the IE shall be a Broadcast CID. (See Table 402.)

</tr>
</tbody>
</table>

The UL Fast Tracking IE is an optional field in the UL-MAP. When this IE is sent it provides an indication about corrections that should be applied by MSs that have transmitted in the frame before the previous UL frame. Each Indication byte shall correspond to one unicast allocation-IE or sub-IE that has specified an allocation of an UL transmission in the UL-MAP transmitted 2 frames before the previous frame. The order of the indication bytes shall be the same as the order of the unicast allocation IE in the UL-MAP.

The response time for corrections following receipt of this IE shall be equal to Ranging Response Processing Time as defined in 10.1.
8.4.5.4.21 Anchor BS Switch IE

The Anchor BS Switch IE may be sent by a BS to indicate to one or more MS(s) to switch to a new specified Anchor BS at specific action time, or to cancel the switch. The Anchor BS Switch IE can also be used to allocate CQICH at the new Anchor BS. (See Table 403.)

8.4.5.4.22 HARQ UL-MAP IE

The following modes of HARQ shall be supported by the HARQ UL-MAP IE:

a) Chase combining HARQ for all FEC types (HARQ Chase). In this mode, the burst profile is indicated by a UIUC.

b) Incremental redundancy HARQ for CTC (HARQ IR). In this mode, the burst profile is indicated by the parameters $N_{EP}$, $N_{SCH}$.

c) Incremental redundancy HARQ for convolutional code (HARQ CC-IR).

The IE may also be used to indicate a non-HARQ transmission when ACK disable=1.

The HARQ UL MAP IE defines one or more bursts. Each burst is separately encoded.

When Allocation Start Indication is 1, the HARQ UL-MAP IE indicates the starting symbol and subchannel of the allocation. The starting symbol and subchannel shall indicate a valid slot location after the last allocation in the uplink zone in the UL subframe. The slots are allocated in a time-first order (as specified in 8.4.5.4). The starting symbol and subchannel are relevant only in the context of the HARQ UL-MAP IE in which they appear. Allocations made without the starting symbol and subchannel of the allocations specified (such as HARQ UL-MAP IE with Allocation Start Indication 0, or regular UL-MAP IE) shall immediately follow the last allocation in the uplink zone and shall advance in the time axis. (See Table 404 through Table 408.)

For FDD/H-FDD, if the HARQ UL-MAP IE with H-FDD UL Subframe Indicator = 1 is included in the FDD_Paired_Allocation_IE(), the “OFDMA Symbol Offset” and “Subchannel Offset” fields in HARQ UL-MAP IE indicates the starting symbol and subchannel of the allocation in the other UL subframe (Group) in the same frame, that is, the UL Group different from that the UL-MAP including the current HARQ UL-MAP IE is associated with.

If H-FDD UL Subframe Indicator is set to '0', the HARQ UL-MAP IE indicates the starting symbol and subchannel of the allocation in the UL subframe (Group) that the UL-MAP including this HARQ UL-MAP IE is associated with. BS shall not use UL Allocation Start Indication = 1 with H-FDD UL Subframe Indicator=1 to an MS without capability of Full-Duplex (FDD), which is negotiated using SBC-REQ/RSP.

Length
A field that indicates the following control information.

Control Information
Variable size control information.

SDMA control information
The Dedicated UL Control IE with SDMA Control Info = 1 shall be present within the first subburst allocation of each layer of SDMA allocations. When the SDMA control info is present, the OFDMA Symbol offset and Subchannel offset shall be reset to the Start OFDMA Symbol offset and Start Subchannel offset of the HARQ UL MAP IE. The specified pilot pattern for PUSC (see 8.4.8.1.5) or for AMC (see 8.4.8.4.1) is used for all subburst allocations until the next occurrence of SDMA Control Info or until the end of the current HARQ UL MAP IE. The information specified in this SDMA control info is first applied to the same subburst allocation that contains the Dedicated UL Control IE.
8.4.5.4.22.2 Dedicated MIMO UL Control IE format

Dedicated MIMO UL Control IE contains additional control information for each subburst. (See Table 413.)

8.4.5.4.23 HARQ ACK Region Allocation IE

This IE may be used by the BS to define a UL region to include one or more ACK channel(s) for HARQ supporting MS. The IE format is shown in Table 414. The slots in the ACKCH region are divided into two half-slots. The first half-slot is composed of tiles 0, 2, 4; the second half-slot is composed of tiles 1, 3, 5. In the ACKCH Region, ACK channel 2n is the first half of slot n; ACK channel (2n+1) is the second half of slot n. The slot number n is increased first along the subchannel axis until the end of the ACKCH region, and then along the time axis.

The HARQ-enabled MS that receives HARQ DL burst at frame $i$ should transmit the ACK signal through the ACK channel in the ACKCH region at frame $(i+j)$. The frame offset $j$ is defined by the “HARQ ACK Delay for DL Burst” field in the UCD message. Due to different frame numbering, an H-FDD user in Group 2 shall transmit the ACK signal through the ACK channel in the ACKCH region at frame $(i+j+1)$.

The half-subchannel offset in the ACKCH Region is determined by the order of HARQ-enabled DL burst in the DL MAP. For example, when an MS receives a HARQ-enabled burst at frame $i$, and the burst is the $n$-th HARQ-enabled burst among the HARQ related IEs, the MS should transmit HARQ ACK at $n$-th half-subchannel in ACKCH Region that is allocated by the BS at frame $(i+j)$.

For TDD mode, at most one ACK region per frame may be defined. For FDD/H-FDD mode, at most two ACK regions per frame may be defined (by using up to two HARQ ACK Region Allocation IE-s or TLV-s). If more than one ACK region is defined, the index of the ACK region associated with each burst is specified in a HARQ DL MAP IE and/or a OFDMA SUB-DL-UL-MAP message. The MS accumulates the ACKCH index separately for each ACK region.

Each SS should specify support of “UL ACK” channel (see 11.8.3.5.11).
When the ACK Disable bit is set (in DL HARQ IR CTC Subburst IE format), no ACK channel is allocated for the subburst. (See Table 414.)

<tr>
<td>Specify the start symbol offset, the start subchannel offset, the number of allocated symbols, and the number of subchannels for the HARQ acknowledgement region respectively.</td>
</tr>
</tbody>
</table>

HARQ ACK Region Allocation IE may override fast-feedback region. This means that when the HARQ ACK Region Allocation IE indicates the same region that is allocated for CQICH, then the region shall be used for HARQ ACK region. In the case that the Fast-feedback region is overridden by an HARQ ACK region, the whole HARQ ACK region shall reside within the Fast-feedback region. The BS and MS shall treat the overridden part of the Fast-feedback region as an HARQ ACK region. The original CQICH allocation offsets remain unchanged. When allocating Fast-feedback slots, the BS shall skip the slots in the overridden region.

8.4.5.4.24 UL Sounding Command IE

UL Sounding Command IE is defined in Table 464 (in 8.4.6.2.7.1).

8.4.5.4.25 AAS SDMA UL IE format

8.4.5.4.26 Feedback Polling IE

This IE may be used by BS to schedule feedback header transmission by the MS. When the Dedicated UL Allocation bit is set to 1, a dedicated UL allocation shall be included in this IE. The dedicated UL allocation shall be used by the MS to transmit feedback header at the designated feedback header transmission frame defined by this IE. When the Dedicated UL Allocation bit is set to 0, no dedicated UL allocation shall be included. Instead, at the designated transmission frame defined by this IE, the MS shall compose the feedback header and the BS shall include a dedicated UL allocation for the transmission using normal UL MAP IE. (See Table 416).

Feedback type
See Table 17.

Duration
In OFDMA slots (see 8.4.3.1).

Period (p)
The UL resource region is dedicated to an MS in every $2^p$ frame.

Dedicated UL Allocation
0: No dedicated UL resource is allocated in feedback polling IE. BS shall provide UL allocation for the feedback header transmission at each designated transmitting frame defined by this IE.
1: Dedicated UL resource is included.

OFDMA symbol offset
The offset of OFDMA symbol in which the burst starts, measured in OFDMA symbols from beginning of the designated transmission UL frame for feedback header.

Subchannel offset
The lowest index OFDMA subchannel used for carrying the burst, starting from subchannel 0.

Allocation Duration (d)
The allocation is valid for $4^{(d-1)}$ frame starting from the frame defined by Frame offset
If $d == 0b000$, the dedicated allocation is deallocated.
If $d == 0b111$, the dedicated resource shall be valid until the BS commands to deallocate the dedicated allocation.
8.4.5.4.27 Uplink Power Control Bitmap IE

This IE defines uplink power control correction bitmaps (UL_PC_Bitmap_IE). The value in the Power Control Bitmap is the change that MS applies to its transmit power by changing the offset value. (See Table 417).

8.4.5.4.28 Persistent HARQ UL MAP Allocation IE

Uplink persistent allocations are used by the base station to make uplink time-frequency resource assignments which repeat periodically. The logical time-frequency resource assigned using the Persistent HARQ UL MAP IE repeats at a periodic interval. Uplink persistent allocations are not compatible with the HARQ ACK bitmap.

The Persistent HARQ UL MAP IE may be used for non persistent allocations by setting the persistent flag in the subburst IE to 0.

Resource Shifting Indicator

If the resource shifting indicator is set to 1, the MS shall shift its persistent resource position by the accumulated slots as indicated by de-allocation commands with slot offsets smaller than its own.

Persistent Region ID

The identifier of specific Persistent HARQ region. The operation commanded by the IE is applied to subbursts in the region.

Change Indicator

The change indicator can be set to 0 or 1. It is used by MSs to decide if they can resume using their UL persistent allocations. See 6.3.26.4.5 for details.

<tr>
<td>ACK Disable</td>
<td>1</td>
<td>When ACK Disable == 1, the allocated subburst does not require an ACK to be transmitted by the BS in the HARQ ACK BITMAP (see 8.4.5.3.22). In this case, no bit position is allocated for the subburst in the HARQ ACK BITMAP. For TDD SS, for the burst, MS shall not perform HARQ retransmission and ignore ACID, AI_SN and SPIID, which shall be set to 0 by BS if they exist. For FDD SS, the BS may set the ACID to a value other than 0 if that ACID is listed in the Aggregated HARQ Channels TLV. The CRC shall be appended at the end of each subburst regardless of the ACK disable bit.</td>
</tr>
<tr>
<td>Padding</td>
<td>variable</td>
<td>Padding to nibble; shall be set to 0.</td>
</tr>
</tbody>
</table>

Allocation flag
The allocation flag shall be set to 1 if the subburst IE is allocating time-frequency resources and shall be set to 0 if the subburst IE is de-allocating resources.

Retransmission Flag
The Retransmission Flag shall be set to 0 if the de-allocation occurs in K, where K is the relevant frame and shall be set to 1 if the de-allocation occurred in frame $K - \text{allocation period}$. The MS, who correctly received the UL-MAP in the frame relevant to frame $K - \text{allocation period}$, shall ignore the deallocation command with Retransmission Flag equal to 1. The MS, who failed to receive the UL-MAP in the frame relevant to frame $K - \text{allocation period}$, shall process the deallocation command with Retransmission Flag equal to 1.

The BS is allowed to retransmit de-allocation commands with the retransmission flag not set. This may cause the MS to receive a duplicated de-allocation command. The MS shall ignore a de-allocation command for which it does not have a corresponding persistent resource allocation.

Persistent Flag
The persistent flag shall be set to 1 if the assignment is persistent and shall be set to 0 if the assignment is non-persistent.

Slot Offset
The slot offset shall be set to the first slot in the time-frequency resource assignment. The slot offset is defined with respect to the lowest numbered slot of the UL subframe if an allocation start indication is not included in this IE, and the slot offset is defined with respect to the indicated OFDM symbol offset and subchannel offset if an allocation start indication is included in this IE.

Allocation Period
The allocation period value shall be set to $(ap - 1)$ where ap is the period of the persistent allocation, in units of frames.
N_ACID
The values of ACID field (N0) and N_ACID field (N) are used together to specify an implicit
cycling of HARQ channel identifiers as follows. N0 is used as the HARQ channel identifier
Corresponding to the first occurrence of the persistent allocation. For each next allocation this
value is incremented modulo (N + 1)

MAP NACK Channel Index
The MAP NACK channel index is persistently allocated within the Fast Feedback region. The
Mobile station shall use the indicated MAP NACK channel to report MAP decoding error in
frames where it has a persistent resource allocation assigned. When MAP NACK Channel
Index = 0b111111, it indicates NO MAP NACK channel is assigned to this allocation.

MAP ACK Channel Index
The MAP ACK channel is allocated non-persistently within the Fast Feedback region. The
Mobile station shall use the indicated MAP ACK channel to report successful receipt of the per-
sistent allocation IE. If the allocation flag is set to 0, when MAP ACK Channel Index =
0b111111, it indicates NO MAP ACK channel is assigned to this deallocation.

ACID
The ACID field shall be set to the initial value of HARQ channel identifier as described above.

AI_SN
The AI_SN field value shall be set to the initial ARQ identifier sequence number for each
HARQ channel. The AI_SN toggles between 0 and 1 for each particular HARQ channel. For
example, if the period equals 4 frames, N_ACID = 0b011, ACID = 2, and AI_SN = 0, the
ACID follows the pattern 2, 3, 4, 5, 2, 3, 4, 5, etc, and the AI_SN follows the pattern 0, 0, 0, 0,
1, 1, 1, 1, etc.

8.4.5.4.29 FDD Paired Allocation IE

When one or more FDD UL allocations are made in the other UL Group (that is, the UL Group different from the group to which the current UL-MAP belongs) in the generic FDD/H-FDD frame, the extended UIUC = 11 shall be used with the subcode 0x13 to notify FDD MSs of their allocation. H-FDD MSs shall ignore the FDD Paired Allocation IE. (See Table 426.)

8.4.5.5 Burst profile format

Table 427 defines the format of the Downlink Burst Profile TLV, which is used in the DCD message (6.3.2.3.1). The DL burst profile is encoded with a type of 1, an 8-bit length, and a 4-bit DIUC. The DIUC field is associated with the DL burst profile and thresholds. The DIUC value is used in the DL-MAP message to specify the burst profile to be used for a specific DL burst.

</table>
DIUC/UIUC for mandatory CC shall be referred to the Downlink/Uplink Burst Profile with type = 1. If there is no DL(UL) burst profile with type of 153(202), MSs shall refer to DL(UL) burst profile with type of 1. The burst transmitted without CID in the DL-MAP IE shall be encoded using DIUC specified in the DL burst profile with type of 1. This capability is determined by SBC-REQ/RSP (see 11.8.3.5.14).

MAP IEs that do not contain a CID or that contain broadcast/multicast CIDs shall always use type 1 DIUC (see Table 427).

### 8.4.5.6 Compressed maps

In addition to the standard DL-MAP and UL-MAP formats described in 6.3.2.3.2 and 6.3.2.3.4, the DL-MAP and UL-MAP may conform to the format presented in 8.4.5.6.1 and 8.4.5.6.2. The presence of the compressed DL-MAP format is indicated by the contents of the most significant three bits of the first data byte. The first three bits overlay the HT, EC, and most significant bit of Type field in a generic MAC header. When this combination of three bits is set to 110 (an invalid combination for a standard header in the downlink), the compressed DL-MAP format is present. A compressed UL-MAP shall only appear after a compressed DL-MAP. The presence of a compressed UL-MAP is indicated by a bit in the compressed DL-MAP data structure.

The compressed map shall occur directly after the DL Frame Prefix, or can be used as a private map in an AAS zone. When located after the DL Frame Prefix, the burst containing the Compressed DL-MAP (and appended UL-MAP) shall not contain any other messages and shall be mapped to slots in the same manner as the DL-MAP. When located in an AAS zone, the private map can be pointed to by a broadcast map, the AAS DLFP message, or another private map in a previous frame. Other restrictions of private maps include the following:

- The private map shall be the first message in a PHY burst.
- Private maps are only allowed to use unicast CID values.
- Allocations pointed to by a private map must occur within the same AAS zone as the private map.
- Both UL and DL allocations included in the private map are relative to the next frame + frame offset value negotiated with the SS (see 11.8.3.5.6).

When a private map chain is started that has UL IE, an AAS UL IE shall be included in the first UL map so the AAS zone information is known by the SS. This information only needs to be included in the first private map of a private map chain, or after any parameters in the AAS zone is changed. The DL zone information is expected to be static for the duration of the private map chain; however, a AAS DL IE can be included to change the DL AAS zone parameters. The private map is an optional feature that can be negotiated between the SS and BS. In addition, there is a capability bit to indicate if an SS can support private map chains. This is to support applications that utilize private maps but do not require chains.
8.4.5.6.1 Compressed DL-MAP

The compressed DL-MAP format is presented in Table 431. The message presents the same information as the standard format with one exception. In place of the DL-MAP’s 48-bit Base Station ID parameter, the compressed format provides a subset of the full value. When the compressed format is used, the full 48-bit Base Station ID parameter shall be published in the DCD.

</table>
Compressed map indicator
A value of binary 11 in this field indicates the map message conforms to the compressed format described here. A value of binary 00 in this field indicates the map message conforms to the standard format described in 6.3.2.3.2. Any other value is an error.

UL-MAP appended
A value of 1 indicates a compressed UL-MAP (see 8.4.5.6.2) is appended to the current compressed DL-MAP data structure.

Map message length
This value specifies the length of the compressed map message(s) beginning with the byte containing the Compressed map indicator and ending with the last byte of the compressed DL-MAP message if the UL-MAP appended bit is not set or the last byte of the UL-MAP compressed message if the UL-MAP appended bit is set. The length includes the computed 32-bit CRC value.

PHY Synchronization
This field holds frame number and frame duration information. See 8.4.5.1 and Table 319.

DCD Count
Matches the value of the configuration change count of the DCD, which describes the DL burst profiles that apply to this map.

Operator ID
This field holds the 8 LSBs of the 24 MSBs of the 48-bit Base Station ID parameter.

Sector ID
This field holds the 8 LSBs of the 48-bit Base Station ID parameter.

DL IE count
This field holds the number of IE entries in the following list of DL-MAP IEs.

A CRC-32 value shall be appended to the end of the compressed map(s) data. The CRC is computed across all bytes of the compressed map(s) starting with the byte containing the compressed map indicator through the last byte of the map(s) as specified by the map message Length field. The CRC calculation is the same as that used for standard MAC messages.

In case the UL-MAP is not appended to the DL-MAP, the UL-MAP (if such exists) message shall be always transmitted on the burst described by the first DL-MAP IE of the DL-MAP.
8.4.5.6.2 Compressed UL-MAP

The compressed UL-MAP format is presented in Table 432. The message may only appear after a compressed DL-MAP message to which it shall be appended. The message presents the same information as the standard format with the exception that the generic MAC header is omitted.

</tr>
</tbody>
</table>

Frame Number  
The 8 LSBs of the frame number in which to start the measurement.

Number of Frames  
The number of frames over which to measure.

Measurement Data Type  
Indicates the type of data on which the measurement is carried out. If the Measurement Data Type field entry is set to 1, the measurement is carried out over all DL bursts for this SS during the period, which is indicated by Frame Number and Number of Frames. The measurement thereby extends over the DL bursts as a whole, including AAS DL preambles.

Feedback Request Counter  
Increases every time an AAS-FBCK-REQ is sent to the SS. Individual counters shall be maintained for each SS. The value 0 shall not be used.

Frequency measurement resolution  
Indicates the frequency measurement points on which to report. Measurement points shall be on the frequencies corresponding to the negative subcarrier offset indices $-N_{used}/2 + n$ times the indicated subcarrier resolution and corresponding to the positive subcarrier offset indices $N_{used}/2 - n$ times the indicated subcarrier resolution where $n$ is a positive integer. In case of measurement on the DL data (value 1 of the Measurement Data Type field), only the frequencies occurring in the allocations of the addressed SS shall be reported.

The format of the AAS Feedback Response message body is shown in Table 434.

Feedback Request Counter  
Counter from the AAS-FBCK-REQ messages to which this is the response. The value 0 indicates that the response is unsolicited. In this case, the measurement corresponds to the preceding frame.

Re(Frequency_value[i]) and Im(Frequency_value[i])  
The real (Re) and imaginary (Im) part of the mean measured complex amplitude on the frequency measurement point (low to high frequency) in signed integer fixed point format ($[\pm][2 \text{ bits}].[5 \text{ bits}]$).
RSSI mean value
The mean RSSI as measured on the element pointed to by data measurement type, frame number and number of frames in the corresponding request. The RSSI is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.

CINR mean value
The mean CINR as measured on the element pointed to by data measurement type, frame number, and number of frames in the corresponding request. The CINR is quantized as described in 8.3.9.2. When the AAS feedback response is unsolicited, this value corresponds to preceding frame.

8.4.5.8 Optional reduced AAS private maps
Reduced AAS private maps are based upon the compressed map format, however they are specifically designed to support a single unicast IE per map. Their use is identical to compressed private maps, however, fields have been removed that are not require to support a single IE. The reduced AAS private map shall be pointed to by a broadcast map or private compressed map, which shall define the values of several fields that shall be constant for the duration of the private map chain. The behavior of the compressed map fields that are not present in the reduced AAS private map are described below:

a) Frame Duration. Acquired by the map that initiated the private map chain. Assumed constant for the duration of the private map chain.
b) Frame Number. Acquired by the map that initiated the private map chain. Counted by the SS for the duration of the private map chain.
c) DCD Count. Optionally included. Only required if DCD count changes.
d) Operator ID. Acquired by the map that initiated the private map chain. Assumed constant for the duration of the private map chain.

e) **Sector ID.** Acquired by the map that initiated the private map chain. Assumed constant for the duration of the private map chain.

f) **CID.** Only required in first map of private map chain.

g) **UCD Count.** Optionally included. May be sent in the first UL map of private map chain. If not included, the last received UCD Count shall be used.

h) **Allocation Start Time.** Optionally defined by Private Map Allocation Start Time, which may be sent in the first UL map of private map chain. If not included, the UL subframe start time is assumed to be static and defined by the last received Allocation Start Time in an UL map.

### 8.4.5.9 Reduced AAS private maps

#### 8.4.5.9.1 Reduced AAS private DL-MAP

The reduced AAS private DL-MAP format is presented in Table 435. The reduced AAS private DL-MAP message eliminates the fields that are not relevant since the message is targeted to a single CID. The DL_PermBase of the zone containing the assigned DL allocation is assumed to have the same value as the zone in which the compressed private DL-MAP message is located.

</table>

A CRC 16-CCITT, as defined in ITU-T Recommendation X.25, shall be included at the end of each reduced private map. The CRC is computed across all bytes of the reduced map, including the appended UL map if included, starting with the byte containing the compressed map indicator through the last byte of the map including padding.

The “DL Frame Offset” and “UL Frame Offset” fields define the latency between the Reduced Private Map and the DL or UL allocation made by the Reduced Private Map. This is valid for all values of the “Periodicity” field. A Reduced Private Map with Periodicity = 00 indicates single allocation or termination of a periodic chain of private map allocations if such chain is established.
8.4.5.9.2 Reduced AAS private UL-MAP

The reduced AAS private UL-MAP format is presented in Table 436. The message may only appear after a reduced AAS private DL-MAP message to which it shall be appended.

</table>
8.4.6 OFDMA subcarrier allocations

For OFDMA, $F_s = \text{floor}(n \times BW/8000) \cdot 8000$ where $n$ is the sampling factor which is dependent on bandwidth. Subtracting the guard tones from $N_{FFT}$, one obtains the set of “used” subcarriers $N_{\text{used}}$. For both UL and DL, these used subcarriers are allocated to pilot subcarriers and data subcarriers. However, there is a difference between the different possible zones. For FUSC and PUSC, in the DL, the pilot tones are allocated first; what remains are data subcarriers, which are divided into subchannels that are used exclusively for data. For PUSC in the UL, the set of used subcarriers is first partitioned into subchannels, and then the pilot subcarriers are allocated from within each subchannel. Thus, in FUSC, there is one set of common pilot subcarriers, and in PUSC of the DL, there is one set of common pilot subcarriers in each major group. However, in PUSC of the UL, each subchannel contains its own set of pilot subcarriers.

8.4.6.1 Downlink (DL)

The DL can be divided into a three-segment structure. A preamble begins the transmission. This preamble uses one of the three carrier-sets specified in 8.4.6.1.1.

Figure 243 illustrates the DL transmission basic structure.
8.4.6.1.1 Preamble

The first symbol of the DL transmission is the preamble. For each FFT size, three different preamble carrier-sets are defined, differing in the allocation of subcarriers. Those subcarriers are modulated using a boosted BPSK modulation with a specific pseudo-noise (PN) code.

The preamble carrier-sets are defined using Equation (61).

\[ PreambleCarrierSet_n = n + 3k \]  

(61)

where

- \( PreambleCarrierSet_n \) specifies all subcarriers allocated to the specific preamble
- \( n \) is the designating number of the preamble carrier-set indexed 0, 1, and 2
- \( k \) is a running index. 0-567 for 2K-FFT, 0-283 for 1024-FFT, 0-142 for 512-FFT, and 0-35 for 128-FFT

Each segment uses a preamble composed of a single carrier-set in the following manner:

- Segment 0 uses preamble carrier-set 0.
- Segment 1 uses preamble carrier-set 1.
- Segment 2 uses preamble carrier-set 2.

In the case of segment 0, the DC carrier will not be modulated at all, and the appropriate PN will be discarded. Therefore, the DC carrier shall always be zeroed.

Each segment eventually modulates each third subcarrier. As an example, Figure 244 depicts the preamble of segment 1 in the case of the 2048-FFT. In this figure, subcarrier 0 corresponds to the first subcarrier used in the preamble symbol.
In the case of 2048-FTT, the PN series modulating the preamble carrier-set is defined in Table 437. The series modulated depends on the segment used and IDcell parameter. The defined series shall be mapped onto the preamble subcarriers in ascending order. In the case of 2048-FTT, Table 437 includes the PN sequence in an hexadecimal format. The value of the PN is obtained by converting the series to a binary series ($W_k$) and mapping the PN starting from the MSB of each symbol to the LSB (0 mapped to +1 and 1 mapped to –1). For example, for Index = 0 and Segment = 0, $W_k = 110000010010...$, and the mapping shall follow: –1 –1 +1 +1 +1 +1 +1 –1 +1 +1 −1 +1 ...).

In the case of 2048-FTT, the preamble symbol will include 86 guard band subcarriers on each side of the spectrum.

For 1024-FFT size, the PN series modulating the preamble carrier-set is defined in Table 438. For the preamble symbol, there will be 86 guard band subcarriers on each side of the spectrum.

For 512-FFT size, the PN series modulating the preamble carrier-set is defined in Table 439. However, in this case, the final bit of the 144-bit series shown in each row of the table shall be discarded, so that the series used is 143 bits long. For the preamble symbol, there will be 42 guard band subcarriers on the left (lower-frequency) side and 41 guard band subcarriers on the right (higher-frequency) side of the spectrum.

For 128-FFT size, the PN series modulating the preamble carrier-set is defined in Table 440. For the preamble symbol, there will be 10 guard band subcarriers on each side of the spectrum.

The modulation used on the preamble is defined in 8.4.9.4.3.1.

Table 440—Preamble modulation series per segment and IDcell for the 128-FFT mode (continued)
8.4.6.1.1 Common SYNC symbol (optional)

In every fourth DL transmission frame, the last OFDM symbol is the common SYNC symbol; it can be transmitted by the BSs in the 1024-/512-/128-FFT modes by antenna #0. The mapping of the common SYNC sequence to the common SYNC symbol subcarrier is defined by using the following formula:

\[
Common\_SYNC\_Carrier\_Set = N_{LEFT-FFT} + 2k - 1
\]

where

\[k\]

is the number of the running index \(1 \ldots \left(\frac{N_{FFT} - N_{LEFT-FFT} - N_{RIGHT-FFT} - 1}{2}\right)\), where \([x]\) denotes the smallest integer number greater than \(x\).

\(N_{LEFT-FFT}\) and \(N_{RIGHT-FFT}\)

are the numbers of guard subcarriers of the left band and right band of FFT size \(N_{FFT}\) respectively. The values of \(N_{LEFT-FFT}\) and \(N_{RIGHT-FFT}\) for 1024-/512-/128-FFT modes are listed in Table 438, Table 439, and Table 440, and the DC carrier shall always be zeroed.

The common SYNC symbol is defined by frequency domain as shown in Figure 245, and the time domain illustration is shown in Figure 246.

The same common SYNC symbol is transmitted by all BSs across the network synchronously.

8.4.6.1.1.2 Common SYNC symbol sequence

The common SYNC sequences are listed in Table 441. The defined sequences shall be mapped onto the common SYNC symbol subcarriers in ascending order. The sequences in Table 438 are in an hexadecimal format, and the value of the sequences should be converted to binary sequences (0 mapped to +1 and 1 mapped to −1). The converted binary sequences are mapped onto the corresponding subcarriers from the MSB to the LSB.
8.4.6.1.2 Symbol structure

8.4.6.1.2.1 Symbol structure for PUSC

The symbol structure is constructed using pilots, data, and zero subcarriers. The symbol is first divided into basic clusters and zero carriers are allocated. Pilots and data carriers are allocated within each cluster. Table 442 summarizes the parameters of the symbol structure.

Figure 247 depicts the cluster structure.

![Cluster structure diagram](image)

Figure 247—Cluster structure

Figure 247 shows subcarriers from left to right in order of increasing subcarrier index. For the purpose of determining PUSC pilot location, odd and even symbols are counted from the beginning of the current zone. The first symbol in the zone is even. The preamble shall not be counted as part of the first zone.

8.4.6.1.2.1.1 DL subchannels subcarrier allocation in PUSC

The carrier allocation to subchannels is performed using the following procedure:

a) Dividing the subcarriers into the number of clusters \( N_{\text{clusters}} \) physical clusters containing 14 adjacent subcarriers each (starting from carrier 0). The number of clusters, \( N_{\text{clusters}} \), varies with FFT sizes. See Table 442, Table 443, Table 444, and Table 445 for details.

b) Renumber the physical clusters into logical clusters. If the physical clusters are placed in the first DL zone or \textit{Use All SC} = 0 in the STC_DL_Zone_IE, then \( \text{LogicalCluster} = \text{RenumberingSequence}(\text{PhysicalCluster}) \). Otherwise, \( \text{LogicalCluster} = \text{RenumberingSequence}((\text{PhysicalCluster}) + 13 \times \text{DL_PermBase}) \mod N_{\text{clusters}} \).

\[
\text{LogicalCluster} = \begin{cases} 
\text{RenumberingSequence}(\text{PhysicalCluster}) & \text{First DL zone, or Use All SC = 0} \\
\text{RenumberingSequence}((\text{PhysicalCluster}) + 13 \times \text{DL_PermBase}) \mod N_{\text{clusters}} & \text{otherwise} 
\end{cases}
\]

In the first PUSC zone of the DL (first DL zone) and in a PUSC zone defined by STC_DL_Zone_IE() with Use All SC = 0, the default renumbering sequence is used for logical cluster definition. For all other cases, DL_PermBase parameter in the STC_DL_Zone_IE() or AAS_DL_IE() shall be used.

c) Allocate logical clusters to groups. The allocation algorithm varies with FFT sizes.

1) For FFT size = 2048: Dividing the clusters into six major groups, group 0 includes clusters 0–23, group 1 includes clusters 24–39, group 2 includes clusters 40–63, group 3 includes clusters 64–79, group 4 includes clusters 80–103, and group 5 includes clusters 104–119. These groups may be allocated to segments. If a segment is being used, then at least one group shall be allocated to it. (By default, group 0 is allocated to sector 0, group 2 is allocated to sector 1, and group 4 is allocated to sector 2.)

2) For FFT size = 1024: Dividing the clusters into six major groups, group 0 includes clusters 0–11, group 1 includes clusters 12–19, group 2 includes clusters 20–31, group 3 includes clusters 32–39, group 4 includes clusters 40–51, and group 5 includes clusters 52–59. These groups may be allocated to segments. If a segment is being used, then at least one group shall be allo-
cated to it. (By default, group 0 is allocated to sector 0, group 2 is allocated to sector 1, and group 4 is allocated to sector 2.)

3) For FFT size = 512: Dividing the clusters into three major groups (labeled 0, 2, and 4), group 0 includes clusters 0–9, group 2 includes clusters 10–19, and group 4 includes clusters 20–29. These groups may be allocated to segments. If a segment is being used, then at least one group shall be allocated to it. (By default, group 0 is allocated to sector 0, group 2 is allocated to sector 1, and group 4 is allocated to sector 2.)

4) For FFT size = 128: Dividing the clusters into three major groups (labeled 0, 2, 4), group 0 includes clusters 0–1, group 2 includes clusters 2–3, group 4 includes clusters 4–5. These groups may be allocated to segments. If a segment is being used, then at least one group shall be allocated to it. (By default, group 0 is allocated to sector 0, group 2 is allocated to sector 1, and group 4 is allocated to sector 2.)

d) Allocating subcarriers to subchannel in each major group is performed separately for each OFDMA symbol by first allocating the pilot carriers within each cluster and then taking all remaining data carriers within the symbol and using the same procedure described in 8.4.6.1.2.2.2. The parameters vary with FFT sizes.

1) For FFT size = 2048: Use the parameters from Table 442, with basic permutation sequence 12 for even-numbered major groups and basic permutation sequence 8 for odd-numbered major groups, to partition the subcarriers into subchannels containing 24 data subcarriers in each symbol.

2) For FFT size = 1024: Use the parameters from Table 443, with basic permutation sequence 6 for even-numbered major groups and basic permutation sequence 4 for odd-numbered major groups, to partition the subcarriers into subchannels containing 24 data subcarriers in each symbol.

3) For FFT size = 512: Use the parameters from Table 444, with basic permutation sequence 5 for even-numbered major groups, to partition the subcarriers into subchannels containing 24 data subcarriers in each symbol.

4) For FFT size = 128: Use the parameters from Table 445 to partition the subcarriers into subchannels containing 24 data subcarriers in each symbol.

Note that the preamble IDcell is used for the first PUSC zone in Equation (63). Otherwise, the DL_PermBase parameter in the STC_DL_Zone_IE() or AAS_DL_IE() shall be used in the equation. The subcarrier indexing within each group shall start from 0, where 0 is the lowest number subcarrier in the lowest numbered logical cluster belonging to the group.

8.4.6.1.2.2 Symbol structure for FUSC

The symbol structure is constructed using pilots, data, and zero subcarriers. The symbol is first allocated with the appropriate pilots and with zero subcarriers, and then all the remaining subcarriers are used as data subcarriers (these will be divided into subchannels).

There are two variable pilot-sets and two constant pilot-sets. In FUSC, each segment uses both sets of variable/constant pilot-sets. In STC mode (see 8.4.8), each antenna uses half of the pilot set resources compared to that of non-STC mode. Table 446 summarizes the parameters of the symbol.

</tbody>
</table>
The Variable set of pilots embedded within the symbol of each segment shall obey the following rule:

\[
PilotsLocation = VariableSet#x+6 \cdot (FUSC\_SymbolNumber \mod 2) \tag{62}
\]

where \(FUSC\_SymbolNumber\) counts the FUSC symbols used in the current zone starting from 0.
Figure 248 depicts as an example of the symbol allocation for segment 0 on the first symbol.

![Figure 248—DL symbol structure for segment 0 on first symbol using FUSC](image)

8.4.6.1.2.2.1 DL subchannels subcarrier allocation

Each subchannel is composed of 48 subcarriers. The subchannel indices are formulated using a Reed-Solomon series and are allocated out of the data subcarriers domain. The data subcarriers domain includes $48 \times 32 = 1536$ subcarriers, which are the remaining subcarriers after removing from the subcarrier’s domain (0–2047) all possible pilots and zero subcarriers (including the DC subcarrier).

After allocating the data subcarriers domain, the procedure of partitioning those subcarriers into subchannels shall be as specified in 8.4.6.1.2.2.2.

8.4.6.1.2.2.2 Partitioning of data subcarriers into subchannels in DL FUSC

After mapping all pilots, the remainder of the used subcarriers are used to define the data subchannels.

To allocate the data subchannels, the remaining subcarriers are partitioned into groups of contiguous subcarriers. Each subchannel consists of one subcarrier from each of these groups. The number of groups is therefore equal to the number of subcarriers per subchannel, and it is denoted $N_{subcarriers}$. The number of the subcarriers in a group is equal to the number of subchannels, and it is denoted $N_{subchannels}$. The number of data subcarriers is thus equal to $N_{subcarriers} \times N_{subchannels}$.

The exact partitioning into subchannels is according to Equation (63), called a permutation formula. (To clarify the operation of this formula, an example application is given subsequently in 8.4.6.2.3.)

$$
subcarrier(k, s) = N_{subchannels} \cdot n_k + \{p_s[n_4 \mod N_{subchannels}] + DL_{PermBase}\} \mod N_{subchannels}
$$

(63)

where

- $subcarrier(k, s)$ is the subcarrier index of subcarrier $k$ in subchannel $s$
- $s$ is the index number of a subchannel, from the set $[0...N_{subchannels} - 1]$
- $n_k$ is $(k + 13 \cdot s) \mod N_{subcarriers}$ where $k$ is the subcarrier-in-subchannel index from the set $[0...N_{subcarriers} - 1]$
- $N_{subchannels}$ is the number of subchannels (for PUSC, use number of subchannels in the currently partitioned major group)
- $p_s[j]$ is the series obtained by rotating basic permutation sequence cyclically to the left $s$ times
**DL_PermBase** is an integer ranging from 0 to 31, which is set to preamble IDCell in the first zone and determined by the DL-MAP for other zones.

and the numerical parameters are given in Table 446.

On initialization, an SS shall search for the DL preamble. After finding the preamble, the user shall know the IDcell used for the data Subchannels.

### 8.4.6.1.2.3 Additional optional symbol structure for FUSC

The additional optional subchannel structure in the DL supports 32 subchannels where each transmission uses 48 data carriers symbols as their minimal block of processing. In the DL, all the pilot carriers are allocated first, and then the remaining carriers are used exclusively for data transmission. \( N_{\text{used}} \) subcarriers except the DC subcarrier are divided into nine contiguous subcarriers in which one pilot carrier is allocated. The position of the pilot carrier in the nine contiguous subcarriers varies according to the index of the OFDM symbol that contains the subcarriers. If the nine contiguous subcarriers indexed as 0...8, the index of the pilot carrier shall be \( 3 \times l + 1 \) where \( l = m \mod 3 \) (\( m \) is the symbol index). Table 450 summarizes the optional FUSC DL subcarrier allocation parameters.

</tbody>
</table>

Table 451, Table 452, and Table 453 specify parameters for optional FUSC subcarrier allocations for FFT-1024, FFT-512, and FFT-128, respectively.

NOTE—A data symbol is a symbol that overlaps with at least one data slot (regardless of whether data are allocated on that slot).

### 8.4.6.1.2.3.1 DL subchannels subcarrier allocation

To allocate the subchannels, the whole data tones in a symbol are partitioned into groups of contiguous data subcarriers. Each subchannel consists of one subcarrier from each of these groups. The number of groups is, therefore, equal to number of data subcarriers per subchannel, and its value is 48. The number of the subcarriers in a group is equal to the number of subchannels, e.g., \( N_s \). As shown in Table 454, \( N_s \) is determined by FFT size. The exact partitioning into subchannels is according to Equation (64), called the DL permutation formula.

\[
\text{Carriers}(s, m) = \begin{cases} 
N_s \times k + [s + P_{1,c_1}(k') + P_{2,c_2}(k')], 0 < c_1, c_2 < N_s \\
N_s \times k + [s + P_{1,c_1}(k')], c_1 \neq 0, c_2 = 0 \\
N_s \times k + [s + P_{2,c_2}(k')], c_1 = 0, c_2 \neq 0 \\
N_s \times k + s, c_1 = 0, c_2 = 0 
\end{cases}
\] (64)

where

\(\text{Carriers}(s, m)\) is the subcarrier index of \(m\)-th subcarrier in subchannel \(s\)
\(k\) is \((m + s \times 23) \mod 48\)
\(k'\) is \(k \mod (N_s - 1)\)
\(m\) is the subcarrier-in-subchannel index from the set \([0–47]\)
\(s\) is the index number of a subchannel from the set \([0–N_s–1]\)
\(P_{1,c_1}(j)\) is the \(j\)-th element of the sequence obtained by rotating basic permutation sequence \(P_1\) cyclically to the left \(c_1\) times. See Table 454.
\(P_{2,c_2}(j)\) is the \(j\)-th element of the sequence obtained by rotating basic permutation sequence \(P_2\) cyclically to the left \(c_2\) times. See Table 454.
\(c_1\) is \(\text{DL}_\text{-PermBase} \mod N_s\)
\(c_2\) is \(\text{floor}(\text{DL}_\text{-PermBase} \mod /N_s)\)

In Equation (64), the operation in \([\ ]\) is over GF($N_s$). In GF($2^n$), addition is binary XOR operation. For example, \(13 + 4\) in GF($2^3$) is [(1101)$_2$ XOR (0100)$_2$] = (1001)$_2$ = 9, where $(x)_2$ represents binary expansion of $x$. Also, $P_1, P_2$ permutation sequences shall be taken from Table 454. $k'$ shall be calculated as follows: $k' = k \mod (\text{length of permutation sequence})$.

8.4.6.1.2.4 Optional DL tile usage of subchannels—TUSC1

The optional DL TUSC1 is similar in structure to the UL PUSC structure defined in 8.4.6.2. Each transmission uses 48 data subcarriers as the minimal block of processing. The permutation properties are given in Table 455, Table 456, Table 457, and Table 458. The active subchannels in the TUSC1 zone, as defined in the DCD message (see Table 575 in 11.4.1), shall be renumbered consecutively starting from 0.

The pilots in the TUSC1 permutation are regarded as part of the allocation, and as such shall be beamformed in a way that is consistent with the transmission of the allocation’s data subcarriers.

The TUSC1 permutation shall only be used within an AAS zone.

8.4.6.1.2.4.1 Symbol structure for TUSC1 subchannels

The TUSC1 symbol structure corresponds to that of the UL PUSC structure as defined in 8.4.6.2.1.

8.4.6.1.2.4.2 Partitioning of subcarriers into TUSC1 subchannels

The partitioning of subcarriers into tiles and tiles into subchannels corresponds to the definitions for the UL PUSC structure as defined in 8.4.6.2.2 with \( \text{UL} \_\text{Permbase} \) replaced by \( \text{IDcell} \).

8.4.6.1.2.5 Optional DL tile usage of subchannels—TUSC2

The TUSC2 is similar in structure to the UL PUSC structure defined in 8.4.6.2.5. Each transmission uses 48 data subcarriers as the minimal block of processing. The permutation properties are given in Table 460, Table 461, Table 462, and Table 463. The active subchannels in the TUSC2 zone, as defined in the DCD message (see Table 575 in 11.4.1), shall be renumbered consecutively starting from 0.

The pilots in the TUSC2 permutation are regarded as part of the allocation, and as such shall be beamformed in a way that is consistent with the transmission of the allocation’s data subcarriers.

The TUSC2 permutation shall only be used within an AAS zone.

8.4.6.1.2.5.1 Symbol structure for TUSC2 subchannels

The TUSC2 symbol structure corresponds to that of the UL optional PUSC structure as defined in 8.4.6.2.5.1.

8.4.6.1.2.5.2 Partitioning of subcarriers into TUSC2 subchannels

The partitioning of subcarriers into tiles and tiles into subchannels corresponds to the definitions for the UL optional PUSC structure as defined in 8.4.6.2.5.2.

8.4.6.1.2.6 TUSC1/TUSC2 support for SDMA

The pilots in an AAS zone with TUSC1 or TUSC2 permutation are regarded as part of the allocation, and as such shall be beamformed in a way that is consistent with the transmission of the allocation’s data subcarriers. In an SDMA region, the pilots of each allocation may correspond to a different pilot pattern. The pilot patterns for TUSC1 permutation are as depicted in Figure 263, and the patterns for the TUSC2 permutation are as depicted in Figure 275.

8.4.6.2 Uplink (UL)

The following subclause defines the UL transmission and symbol structure. The UL follows the DL model, therefore it also supports up to three segments.

The UL supports 70 subchannels for PUSC permutation and 96 subchannels for optional PUSC permutation. Each transmission uses 48 data carriers as the minimal block of processing. Each new transmission for the UL commences with the parameters given in Table 455 for PUSC permutation and with the parameters given in Table 460 (in 8.4.6.2.5) for optional PUSC permutation.

8.4.6.2.1 Symbol structure for subchannel (PUSC)

A slot in the UL is composed of three OFDMA symbols and one subchannel. Within each slot, there are 48 data subcarriers and 24 fixed-location pilots as shown in Table 455.

The subchannel is constructed from six UL tiles. Each tile has four successive active subcarriers, and its configuration is illustrated in Figure 249.

8.4.6.2.2 Partitioning of subcarriers into subchannels in the UL

The usable subcarriers in the allocated frequency band shall be divided into \( N_{\text{tiles}} \) physical tiles as defined in Figure 249 with parameters from Table 459 (in 8.4.6.2.4). The allocation of physical tiles to logical tiles in subchannels is performed in the following manner:

Logical tiles are mapped to physical tiles in the FFT using Equation (65); for an example, refer to 8.4.6.2.3.

\[
Tiles(s, n) = N_{\text{subchannels}} \cdot n + (Pr[(s + n)mod N_{\text{subchannels}}] + UL_{\text{PermBase}})mod N_{\text{subchannels}}
\]

where

\( Tiles(s, n) \) is the physical tile index in the FFT with tiles being ordered consecutively from the most negative to the most positive used subcarrier (0 is the starting tile index)
After mapping the physical tiles in the FFT to logical tiles for each subchannel, the data subcarriers per slot are enumerated by the following process:

a) After allocating the pilot carriers within each tile, indexing of the data subcarriers within each slot is performed starting from the first symbol at the lowest indexed subcarrier of the lowest indexed tile, continuing in an ascending manner through the subcarriers in the same symbol, then going to the next symbol at the lowest indexed data subcarrier, and so on. Data subcarriers shall be indexed from 0 to 47.

b) The mapping of data onto the subcarriers shall follow Equation (66). This equation calculates the subcarrier index (as assigned in item 1) to which the data constellation point is to be mapped.

\[
\text{Subcarrier}(n, s) = (n + 13 \cdot s) \mod N_{\text{subcarriers}}
\]

where

- \( \text{Subcarrier}(n, s) \) is the permuted subcarrier index corresponding to data subcarrier \( n \) is subchannel \( s \)
- \( n \) is a running index 0…47, indicating the data constellation point
- \( s \) is the subchannel number
- \( N_{\text{subcarriers}} \) is the number of subcarriers per slot

For example, for subchannel 1 (\( s = 1 \)), the first data constellation point (\( n = 0 \)) is mapped onto subcarrier (0,1) = 13, where 13 is the subcarrier with index 13 according to step a) in this subclause. Considering the PUSC tile structure, it can be seen that this is the second indexed subcarrier on the second symbol within the slot. Similarly, for subchannel 3, the ninth data constellation point (\( n = 8 \)) is mapped onto subcarrier (8,3) = 47. According to step a), this is the last indexed subcarrier of the third symbol within the slot.

Subcarrier enumeration shall not be applied to the slots in the UL-MAP indicated by either UIUC = 0, UIUC = 11 (Extended-2 UIUC) with Type=8, UIUC = 12, or UIUC = 13.

### 8.4.6.2.3 UL permutation example

To illustrate the use of the permutations, an example is provided to clarify the operation of the permutation formula, Equation (65).

The tiles used for subchannel \( s = 3 \) in \( \text{UL}_\text{PermBase} = 2 \) are computed.

The relevant parameters characterizing the UL are, therefore, taken from Table 455:

- Number of subchannels: \( N_{\text{subchannels}} = 70 \)
- Number of subcarriers in each OFDMA symbol = 24
- Number of data subcarriers in each slot: \( N_{\text{subcarriers}} = 48 \)
- TilePermutation = \{ 6, 48, 58, 57, 50, 1, 13, 26, 46, 44, 30, 3, 27, 53, 22, 18, 61, 7, 55, 36, 45, 37, 52, 15, 40, 2, 20, 4, 34, 31, 10, 5, 41, 9, 69, 63, 21, 11, 12, 19, 68, 56, 43, 23, 25, 39, 66, 42, 16, 47, 51, 8, 62, 14, 33, 24, 32, 17, 54, 29, 67, 49, 65, 35, 38, 59, 64, 28, 60, 0 \}

Using Equation (65),
a) The basic series of 70 numbers is \( \{6, 48, 58, 57, 50, 1, 13, 26, 46, 44, 30, 3, 27, 53, 22, 18, 61, 7, 55, 36, 45, 37, 52, 15, 40, 2, 20, 4, 34, 31, 10, 5, 41, 9, 69, 63, 21, 11, 12, 19, 68, 56, 43, 23, 25, 39, 66, 42, 16, 47, 51, 8, 62, 14, 33, 24, 32, 17, 54, 29, 67, 49, 65, 35, 38, 59, 64, 28, 60, 0\}.

b) Apply the permutation due to the selection of the subchannel (s), rotate three times: \( \{57, 50, 1, 13, 26, 46, 44, 30, 3, 27, 53, 22, 18, 61, 7, 55, 36, 45, 37, 52, 15, 40, 2, 20, 4, 34, 31, 10, 5, 41, 9, 69, 63, 21, 11, 12, 19, 68, 56, 43, 23, 25, 39, 66, 42, 16, 47, 51, 8, 62, 14, 33, 24, 32, 17, 54, 29, 67, 49, 65, 35, 38, 59, 64, 28, 60, 0, 6, 48, 58\}.

c) Take the first six numbers, and add the `UL_PermBase` (perform modulo operation if needed): \( \{59, 52, 3, 15, 28, 48\} \).

d) Finally, add the appropriate shift: \( \{59, 122, 143, 225, 308, 398\} \).

### 8.4.6.2.4 Partition a slot to mini-subchannels

Mini-subchannels can be applied to PUSC or optional PUSC UL permutations, in which an UL slot is composed of six tiles. Mini-subchannels are created by concatenating multiples of two, three, or six slots and allocating traffic for more than one SS on this concatenation by a subdivision of the tiles. Table 459 shows the four possibilities for slot partitioning into mini-subchannels. The tile indices are those referred to in Equation (65) for the mandatory UL permutation or in Equation (68) (in 8.4.6.2.5.2) for the optional UL permutation.

#### Table 459—Slot partitioning into mini-subchannels

</tr>
</tbody>
</table>

When mini-subchannels of order \( M \) are indicated in the map, the allocation shall be a multiple of \( M \) slots, and shall not exceed one full subchannel, i.e., at most one slot will be allocated in each OFDMA symbol.
Allocating tiles to mini-subchannels shall be done as follows: The slots in the allocation shall be numbered in time-first order in the same order as the slots are allocated in the map. The number of slot modulo $M$ is used as index to Table 459 and determines which tiles are allocated to the SS.

Mapping data to mini-subchannels shall be done as follows: The FEC, repetition, and constellation mapping shall be applied as if the allocation was of duration/$M$ slots (where duration is the number of slots specified in the map). The resulting data subcarriers shall be enumerated in the tiles allocated to each SS in a frequency-first order beginning from the tile with the smallest symbol number and smallest frequency. The subcarrier rotation defined in Equation (66) [step b) of 8.4.6.2.2] shall not be applied to mini-subchannels; instead, enumeration of the data subcarriers shall be performed as indicated by Equation (67), which sets the order to which the mapping of the data onto the subcarriers shall be performed.

$$P(n) = \left( n + 13 \cdot \left\lfloor \frac{n}{48} \right\rfloor \right) \mod 48 + 48 \cdot \left\lfloor \frac{n}{48} \right\rfloor$$  \hspace{1cm} (67)

where

$P(n)$ physical data subcarrier index ($n$)

$n$ is a running index 0… used data subcarriers, which represents the logical subcarrier index

The mini-subchannels are mapped by the UL map like normal slots; except that the mapping is done by the Mini-Subchannel Allocation IE (see 8.4.5.4.8).

### 8.4.6.2.5 Additional optional symbol structure for PUSC

The additional optional subchannel structure for the UL supports 96 subchannels where a subchannel consists of 48 data carriers and 6 pilot carriers. Each new transmission for the UL commences with the parameters as given in Table 460, Table 461, Table 462, and Table 463, according to the FFT size.

8.4.6.2.5.1 Symbol structure for subchannel

A slot in the UL is composed of three OFDMA symbols and one subchannel. Within each slot, there are 48 data subcarriers and six fixed-location pilots. The subchannel is constructed from six UL tiles. Each tile has three successive active subcarriers. Its configuration is illustrated in Figure 250.

![Figure 250—Description of an UL tile](image_url)

8.4.6.2.5.2 Partitioning of subcarriers into subchannels in the UL

To allocate the subchannels, $N_{\text{used}}$ subcarriers excluding DC subcarrier are partitioned into tiles, which are a 3x3 frequency-time block containing 9 tones (1 pilot tones and 8 data tones). The whole frequency band is partitioned into groups of contiguous tiles. Each subchannel consists of 6 tiles, each of which is chosen from different groups. The value of $N_s$ is equal to $N_{\text{tiles}}/18$. $N_{\text{tiles}}$ is the number of tiles in the whole frequency band for each FFT size, which is specified in Table 460, Table 461, Table 462, and Table 463.

There are 18 groups in the whole frequency band, and the number of tiles in a group is $N_s$. In order to make a subchannel, 6 groups at equal distance (3 groups away from each) are chosen, and each of 6 tiles is selected from each group.

The exact partitioning into subchannels is according to Equation (68), called the UL permutation formula.
\[
Tiles(s, m) = \begin{cases} 
3N_s \cdot m + N_s \cdot S + s' + P_{1,c_1}(m') + P_{2,c_2}(m') \quad & 0 < c_1, c_2 < N_s \\
3N_s \cdot m + N_s \cdot S + s' + P_{1,c_1}(m') \quad & c_1 \neq 0, c_2 = 0 \\
3N_s \cdot m + N_s \cdot S + s' + P_{2,c_2}(m') \quad & c_1 = 0, c_2 \neq 0 \\
3N_s \cdot m + N_s \cdot S + s' \quad & c_1 = 0, c_2 = 0 
\end{cases}
\] (68)

where

- \(Tiles(s, m)\) is the tile index of the \(m\)-th tile in subchannel \(s\).
- \(S\) is \(S = \lfloor s / N_s \rfloor, s' = s \mod N_s\).
- \(m\) is the tile-in-subchannel index from the set \([0~5]\), \(m' = m \mod (N_s - 1)\).
- \(s\) is the index number of a subchannel from the set \([0~3N_s - 1]\).
- \(P_{1,c_1}(j)\) is the \(j\)-th element of the sequence obtained by rotating basic permutation sequence \(P_1\) cyclically to the left \(c_1\) times. See Table 456.
- \(P_{2,c_2}(j)\) is the \(j\)-th element of the sequence obtained by rotating basic permutation sequence \(P_2\) cyclically to the left \(c_2\) times. See Table 456.
- \(c_1\) is \(\text{UL\_PermutationBase} \mod N_s\).
- \(c_2\) is \(\text{UL\_PermutationBase}/N_s\).

In Equation (68), the operation in \([\ ]\) is over \(\text{GF}(2^n)\). In \(\text{GF}(2^n)\), addition is binary XOR operation. For example, \(13 + 4 \text{ in } \text{GF}(2^5)\) is \([110101_2 \text{ XOR } 010000_2] = 100101_2 = 9\), where \((x)_2\) represents binary expansion of \(x\).

After allocating the tiles for each subchannel, the data subcarriers of each subchannel are enumerated by the same procedure used for UL PUSC in 8.4.6.2.2.

**8.4.6.2.6 Data subchannel rotation scheme**

A rotation scheme shall be applied per each OFDMA slot duration in any zone, except zones marked as AAS zone, optional PUSC zone (8.4.6.2.5), or zone using the adjacent-subcarriers permutations (8.4.6.3). Slot duration is defined in 8.4.3.1. On each slot duration, the rotation scheme shall be applied to all UL subchannels that belong to the segment (see 8.4.4.6), except the subchannels indicated in the UL-MAP by UIUC = 0, UIUC = 11 (Extended-2 UIUC) with Type = 8, UIUC = 13, or UIUC = 12. The rotation scheme is defined by applying the following rules:

a) Per OFDMA slot duration, pick only subchannels that are not indicated by either UIUC = 0, UIUC = 11 (Extended-2 UIUC) with Type = 8, UIUC = 12, or UIUC = 13 (as defined above). Renumber these subchannels contiguously so that the lowest numbered physical subchannel is renumbered with 0. The total number of subchannels picked shall be designated \(N_{\text{subchn}}\).

b) The mapping function defined by rule a) shall define a function, \(f\), so that \(\text{temp1\_subchannel\_number} = f(\text{old\_subchannel\_number})\).

c) Mark the first UL OFDMA slot duration for each permutation zone with the slot index \(S_{idx} = 0\). Within the permutation zone, increase \(S_{idx}\) by 1 in every slot duration so that subsequent slots are numbered 1, 2, 3, ..., etc.

In FDD/H-FDD, if UL Zone Switch IE is used for the last uplink zone in the first subframe (UL Group2) with H-FDD Inter-UL gap Allocation = 1, the slot index \(S_{idx}\) shall be incremented by 1 in every slot duration up to the last slot in-between two consecutive uplink subframes. If H-FDD Over_subframe Allocation is set to 1 in the UL Zone Switch IE in FDD/H-FDD, the slot index \(S_{idx}\) shall be reset to 0 at the beginning of the first slot duration of the second subframe (UL Group1).
d) Apply the following formula:
\[ \text{temp2}_{\text{subchannel number}} = (\text{temp1}_{\text{subchannel number}} + 13 \times S_{\text{idx}}) \mod N_{\text{subchan}} \]

e) To get the new subchannel number, apply the following formula:
\[ \text{new}_{\text{subchannel number}} = f^{-1}(\text{temp2}_{\text{subchannel number}}) \]

where \( f^{-1}(\cdot) \) is the inverse mapping of the mapping defined in rule b).

f) For subchannels in the UL-MAP indicated by either UIUC = 0, UIUC = 11 (Extended-2 UIUC) with Type = 8, UIUC=12, or UIUC=13, \( \text{new}_{\text{subchannel number}} = \text{old}_{\text{subchannel number}} \).

g) The \( \text{new}_{\text{subchannel number}} \) shall replace the \( \text{old}_{\text{subchannel number}} \) in each allocation defined by 8.4.3.4 where the \( \text{new}_{\text{subchannel number}} \) is the output of the rotation scheme and the \( \text{old}_{\text{subchannel number}} \) is the input of the rotation scheme.

8.4.6.2.7 Optional UL channel sounding in TDD systems

8.4.6.2.7.1 Channel sounding

This subclause describes a signaling mechanism where an MS transmits channel sounding waveforms on the UL to enable the BS to determine the BS-to-MS channel response under the assumption of TDD reciprocity. Only CSIT capable MSs (as indicated by the SBC-REQ message, see 11.8) shall support this signaling. This signaling methodology enables the use of closed loop transmission strategies. Closed Loop transmission strategies use knowledge of the channel at the transmitter to improve link performance, reliability, and range. This methodology also provides a means for the BS to determine the quality of the channel response across the signal bandwidth for the purpose of selecting the best portion of the band on which to transmit. The signaling described in this subclause enables the BS to measure the UL channel response and translate the measured UL channel response to an estimated DL channel response when the Tx and Rx hardware are appropriately calibrated. To support DL channel estimation in a mobile environment, an MS may be instructed to transmit sounding signals periodically. The first sounding symbol is transmitted in the frame containing the relevant sounding instruction if Sounding_Relevance is set to 0. The Sounding_Relevance_Flag indicates whether the Sounding relevance applies to all CIDs in the sounding command or whether a different Sounding Relevance can be applied individually for each CID in the sounding command. For each sounding assignment being made in this IE, the Sounding Relevance cannot be set to 0 unless the respective SS has a sounding response time capability less than or equal to the time between the completion of the transmission of the UL Sounding Command IE and the beginning of its respective sounding assignment.

In order to enable UL sounding, in UL-MAP, a BS transmits UIUC = 13 with the PAPR_Reduction_Safety_and_Sounding_Zone_Allocation_IE() (see Table 378) to indicate the allocation of an UL sounding zone within the frame. The Sounding Zone is a region of one or more OFDMA symbol intervals in the UL frame that is used by the MS to transmit sounding signals to enable the BS to rapidly determine the channel response between the BS and the MS. The BS may command an MS to transmit a sounding signal (defined below) at one or more OFDMA symbols within the sounding zone by transmitting the UL-MAP message UL_Sounding_Command_IE() to provide detailed sounding instructions to the MS. If periodic sounding is instructed by the BS, it is the responsibility of the BS to continue to signal the PAPR_Reduction_Safety_and_Sounding_Zone_Allocation_IE() in every appropriate frame. The UL_Sounding_Command_IE() of type A instructs the MS to transmit the specific sounding signal(s) at one or more specific symbol interval(s) within the sounding zone and specifies the specific sounding frequency band(s) to be occupied within each of these sounding symbol(s). The UL_Sounding_Command_IE() of type B is similar to the UL_Sounding_Command_IE() of type A except the frequency band(s) are allocated according to a specified DL subcarrier permutation. When multiple sounding zones are defined in the UL-MAP or the UCD, the field “sounding zone indicator” is used to explicitly specify for which sounding zone this sounding command IE is referring. Sounding zones are numbered (starting from zero) according to the order in which they appear in the UL MAP or the UCD.
For the purposes of sounding the UL of a CSIT capable MS of type A, the OFDMA frequency bandwidth within the Sounding Zone is partitioned into nonoverlapping sounding frequency bands, where each sounding frequency band contains 18 consecutive OFDMA subcarriers. For the 2048-FFT size, the Sounding Zone, therefore, contains maximum of $\frac{1728}{18} = 96$ sounding frequency bands, where 1728 is the number of usable subcarriers ($N_{\text{used}}$). For other FFT sizes, the sounding bands are also 18 subcarriers wide, and the number of possible sounding bands across the signal bandwidth varies accordingly.

As shown in Table 464, the sounding instructions for CSIT type A include an assigned set of contiguous sounding frequency bands (called the sounding allocation). The sounding frequency bands are nondistributed for CSIT capability type A and are distributed according to a specified DL permutation (for example, PUSC) for CSIT capability type B. For CSIT capability B, distributing the sounding frequency bands according to the optional FUSC is supported only for MSs that support the optional FUSC permutation.

Additionally, for CSIT capability A, the sounding instructions in UL_Sounding_Command_IE() contain two alternate methods of maintaining signal orthogonality between multiple multiplexed MS sounding transmissions. The first methodology is called “cyclic shift separability” and involves the MS occupying all subcarriers within the sounding allocation. With this methodology, multiple MSs use the same sounding sequence (defined below), but each uses a different frequency-domain phase shift to multiply that underlying sounding sequence. In the second methodology, the MS occupies a decimated set of subcarriers (e.g., every 16th subcarrier). Multiple MSs can occupy the same sounding allocation, but each MS would use a set of nonoverlapping subcarriers within the sounding allocation.

The sounding instructions in UL_Sounding_Command_IE() of type B does not allow for multiplexing of sounding transmissions of multiple MSs over the same bands. (See Table 464.)

</tbody>
</table>
If an MS receives a UL Sounding Command IE with Periodicity = 0b000, the MS currently has a periodic sounding allocation and the MS received sounding command IE, which refers to the same frame as the active periodic sounding allocation with parameters identical to those of the active periodic sounding allocation:

- Sounding type
- Separability type
- Max cyclic shift index $P$ (if Separability type $= 0$)
- Decimation value $D$ (if Separability type $= 1$)
- Decimation offset randomization (if Separability type $= 1$)
- Sounding symbol index
- Shorted basic CID
- Allocation mode
- Band bit map (if Allocation mode $= 1$)
- Starting frequency band (if Allocation mode $= 0$)
- Number of frequency bands (if Allocation mode $= 0$)
- Cyclic time shift index $m$ (if Separability type $= 0$)
- Decimation offset $d$ (if Separability type $= 1$)

then the MS shall terminate the active periodic sounding allocation. Otherwise, the MS shall consider the UL Sounding Command IE as a definition of new non-periodic sounding allocation.

If the field “Include Channel Coefficients” is enabled, then the UL Sounding Command IE enables the MS to perform the direct transmission of DL channel coefficients to the BS along with the UL sounding waveform. For the description of the direct channel coefficient encoding method, see 8.4.6.2.7.3.

For CSIT capability A, the indices $d$ or $n$ are associated with the first antenna of the MS. If multi-antenna flag equals 1 then the $i$-th antenna of the MS corresponds to index $d + i - 1$ or to $n + i - 1$ ($i > 0$) respectively. If multi-antenna flag equals 0 then only the first antenna performs sounding. The BS shall assign indices to different CIDs so that overlapping of indices is avoided.

Define $b_k$ as the complex coefficients modulating all subcarriers in the sounding symbol, $0 \leq k \leq N_{used} - 1$ ($N_{used}$ is the value assigned to Band AMC permutations for the respective FFT size), such that the signal transmitted by the MS is defined by Equation (69).
For CSIT capability A, if the separability type is zero, then the sequence used by a Tx device (MS or MS antenna) associated with the \( n \)-th index is determined according to Equation (70).

\[
\begin{align*}
\sum_{k = 0, k \neq \frac{N_{\text{used}} - 1}{2}}^{N_{\text{used}} - 1} e^{j2\pi\left(k - \frac{N_{\text{used}} - 1}{2}\right)}
\end{align*}
\]

(69)

For CSIT capability A, if the separability type is zero, then the sequence used by a Tx device (MS or MS antenna) associated with the \( n \)-th index is determined according to Equation (70).

\[
b_k = \begin{cases} 
2 \cdot \left( \frac{1}{2} - G([k + u + \text{offset}_D(\text{fft}) \mod 2048]) \right) \cdot e^{j\frac{2\pi k u}{P}} & k \in B, k \neq \frac{N_{\text{used}} - 1}{2} \\
0 & \text{otherwise}
\end{cases}
\]

(70)

where

- \( k \) is the subcarrier index (\( 0 \leq k \leq L_s - 1 \))
- \( N_{\text{used}} \) is the number of usable subcarriers in the sounding symbol
- \( G(x) \) is the low PPR Golay sequence as defined in Table 465 (\( 0 \leq x \leq 2047 \))
- \( P \) is the max cyclic shift index (from the sounding instructions)
- \( n \) is the assigned cyclic time shift index (also from the sounding instructions), which ranges from 0 to \( P-1 \)
- \( B \) is the group of allocated subcarriers/bands according to the sounding instructions
- \( u \) is a shift value defined in the PAPR reduction, and safety zone, and sounding zone IE (\( 0 \leq u \leq 127 \))
- \( \text{fft} \) is the FFT size used
- \( \text{offset}_D(\text{fft}) \) is an FFT size specific offset as defined in Table 466

</tr>
</tbody>
</table>

Comment to Table 465: hexadecimal series should be read as a sequence of bits where each 16 bit word is started at the MSB and ends at the LSB where the second word MSB follows. First bit of sequence is referenced as offset 0.

For CSIT type A, if the separability type is one, then the occupied subcarriers are decimated (where \( D \) is the Decimation value) starting with offset \( d \) relative to the first used subcarrier (\( k = 0 \)). The occupied subcarriers
for each transmit device shall be modulated by BPSK symbols extracted from the Golay sequence according to Equation (71).

\[
b_k = \begin{cases} 
2 \cdot \left(\frac{1}{2} - G([k + u + \text{offset}_D(\text{fft}) \mod 2048])\right) & k \in B, k \neq \frac{N_{\text{used}} - 1}{2}, k \mod D = g \\
0 & \text{otherwise}
\end{cases}
\]  

where

- \(k\) is the subcarrier index (\(0 \leq k \leq N_{\text{used}} - 1\), \(N_{\text{used}}\) is the number of usable subcarriers in the sounding symbol)
- \(G(x)\) is the low PAPR Golay sequence as defined in Table 465 (\(0 \leq x \leq 2047\))
- \(\text{fft}\) is the FFT size used
- \(u\) is a shift value defined in the PAPR reduction, and safety zone, and sounding zone allocation IE (\(0 \leq u \leq 127\))
- \(\text{offset}_D(\text{fft})\) is an FFT size specific offset as defined in Table 466
- \(B\) is the group of all allocated subcarriers/bands according to the sounding instructions
- \(D\) is the decimation value (from the sounding command)
- \(g\) is the actual decimation offset (as defined below)

Let \(d\) be the value of the decimation offset \(d\) plus the relative offset according to the MS antenna number (when multi-antenna flag equals 0, then only the first antenna does sounding). If Decimation Offset Randomization equals 0, then \(g = d\), otherwise \(g = (p((\text{IDcell} + \text{Frame Number}) \mod 32) + d) \mod D\), where \(p(x)\) is the value in PermutationBase as defined by Table 446 (in 8.4.6.1.2.2) at the location \(x\). The first subcarrier to be occupied is located at the \(g\)th subcarrier. The pseudo-random cyclic shift of the decimation offset may be used to combat inter-cell interference. On the other hand, when this pseudo-random cyclic shift is not used, then an alternative strategy for combating inter-cell interference involves assigning each neighboring cell/sector a set of decimation offsets that is different from those used by neighboring cells/sectors.

The three periodicity bits indicate whether the MS is to periodically repeat the sounding waveforms in subsequent sounding zone without having to receive a subsequent UL_Sounding_Command_IE(). Setting the periodicity bits to 0b000 has two meanings: Ordinarily, the 0b000 setting means a single sounding command with no periodicity. However, if periodic sounding is being performed by a specified MS, then the 0b000 setting means the specified MS shall stop all sounding over the specified OFDMA symbol.

When the MS is sounding with CSIT capability B, the pilot subcarriers shall be BPSK modulated with their values corresponding to the sequence \(s_u(k)\), where \(k = 0\) is associated with the first occupied subcarrier.
Sequence to subcarrier mapping is done in physical order after collecting all subcarrier index belonging to the allocated subchannels.

If Send Sounding Report Flag is set to one, then any sounding IE (type A or B) encompasses an additional implicit instruction, according to which the MS shall report the average of the DL SINR at the neighborhood of the pilot subcarriers. This instruction is equivalent to a Report command with parameter Channel Type request equal to 0b11. A CSIT capable MS (of type A or type B) shall respond with the appropriate REP-RSP() message on the UL (see also 11.11 and 11.12) within the same frame used to convey the relevant sounding IE. It is the responsibility of the BS to allocate enough bandwidth to support the proper transmission of this REP-RSP() message. In case a periodic sounding is required, a periodic REP-RSP() shall be sent.

For each occupied subcarrier in a sounding symbol, the SINR at the MS is estimated based on a non-beamformed transmission that corresponds to the DL preamble at the first symbol of the frame. The average SINR reported is the average of those estimates. An MS that transmits over multiple sounding symbols shall address the last symbol in the region for that matter.

If the send sounding report flag is set to zero, then no reports are required to be sent by the specified MSs.

### 8.4.6.2.7.2 Power assignment

If inside UL_Sounding_Command_IE() the power assignment method field is set to 0b00 then the mobile shall transmit all pilots with equal power. In general, the transmission power is according to previous commands of the power control mechanism (see 8.4.10.3).

If the power assignment method is 0b10, then the power allocated to each pilot shall be proportional to

\[ Q = \frac{1}{\sigma_k^2} \]

where \( \sigma_k^2 \) is the estimated absolute interference level at the vicinity of the \( k \)-th pilot subcarrier (without normalization to received signal strength at each OFDMA tone). The Tx power shall be normalized so that the maximal power over all tones is the same as the power density of regular data transmission.

If the power assignment method is set to 0b11, then the power allocated to each pilot is set proportional to

\[ Q = \min\{10, \max\{0.1, \frac{\sigma_k^2}{\hat{\sigma}_k^2}\}\} \]

where \( \hat{\sigma}_k^2 \) is the average interference level over the entire spectrum associated with the channel sounding command. The Tx power shall be normalized so that the average power per tone is the same as the power density of regular data.

In both cases, an additional power boost of 3 dB shall be applied if the field power boost is set on.

### 8.4.6.2.7.3 Direct transmission of DL channel coefficients

If the Include Additional Feedback field is set to 0b01, then the UL Sounding Command IE() enables the MS to perform the direct transmission of DL channel coefficients to the BS along with the UL sounding waveform. This functionality provides DL channel state information to the BS in both FDD systems and TDD systems in which BS array transceiver calibration is not implemented. With this functionality enabled, DL channel coefficients are encoded as described below and are transmitted in one or more sounding zone symbols that immediately follow each symbol being used to transmit UL sounding waveforms. In this case, the UL sounding waveform is used by the BS to estimate the UL channel so that the DL channel coefficients transmitted by the MSs can be estimated by the BS. The channel coefficients can then be used to enable closed-loop transmission on the DL.
There are two cases depending on the value of the separability type field. First, if separability type is 0 (cyclic shift separability in the sounding waveform), then a single additional symbol follows each sounding symbol being allocated with the UL_Sounding_Command_IE(). In that additional symbol, an MS antenna that transmits sounding in the sounding symbol will transmit an encoded channel coefficient waveform that occupies the same sounding bands allocated for the sounding waveform. The encoded waveform for the u-th MS (where u is the cyclic shift index in the UL Sounding Command) is defined for two cases: The first case is for where the MS has a single Tx antenna, but multiple receive antennas, and is told with the sounding command IE to sound all antennas (multi-antenna flag set to 1). In this case, the single Tx antenna transmits the sounding waveform appropriate for the single Tx antenna on the sounding symbol and transmits the encoded waveform from Equation (72) in the next symbol interval.

\[
Z_u(k) = \beta_u \cdot \sum_{l=1}^{M_b} \sum_{m=1}^{M_u,u} \hat{H}_{u,m,l}(k) \cdot s_{p(u)}(k) \cdot \exp\{-j2\pi k((m-1)+(l-1) \cdot M_{m,u})/\alpha_u\} \tag{72}
\]

where

\[
\hat{H}_{u,m,l}(k) \quad \text{is the estimated DL channel coefficient between the } l\text{-th BS Tx antenna and the } m\text{-th receive antenna of the } u\text{-th MS for subcarrier } k
\]

\[
\beta_u \quad \text{is a scaling to make the average Tx power of the feedback waveform (averaged across all frequency) of } Z_u(k) \text{ be one}
\]

\[
s_{p(u)}(k) \quad \text{is the sounding sequence of 8.4.6.2.7.1}
\]

\[
M_{m,u} \quad \text{is the number of receive antennas on the } u\text{-th MS}
\]

\[
\alpha_u \quad \text{is } M_{m,u}M_b
\]

\[
M_b \quad \text{is the number of BS Tx antennas}
\]

\[
p(u) \quad \text{in } s_{p(u)}(k) \text{ is equal to } u - j \text{ where } u \text{ is formed from the UL_Permbase and frame number as described in 8.4.6.2.7.1 and } j \text{ is the CID loop index}
\]

The second case for a separability type of 0 is for when the MS has a number of Tx antennas equal to the number of receive antennas. In this case, if the multi-antenna flag is false, then the first antenna of the MS shall transmit the waveform of the preceding equation. If the multi-antenna flag is true, then the encoded waveform to be transmitted by the MS antenna assigned to cyclic shift index of u in the UL Sounding Command is as shown in Equation (73).

\[
Z_u(k) = \beta_u \cdot \sum_{l=1}^{M_b} \hat{H}_{u,l}(k) \cdot s_{p(u)}(k) \cdot \exp\{-j2\pi k(l-1)/\alpha_u\} \tag{73}
\]

where

\[
\hat{H}_{u,l}(k) \quad \text{is the estimated DL channel coefficient between the } l\text{-th BS Tx antenna and the MS antenna assigned to the cyclic shift index of } u \text{ in the UL Sounding Command for subcarrier } k
\]

\[
\beta_u \quad \text{is a scaling to make the average Tx power of the feedback waveform (averaged across all frequency) of } Z_u(k) \text{ be one}
\]

\[
s_{p(u)}(k) \quad \text{is the sounding sequence of 8.4.6.2.7.1}
\]

\[
\alpha_u \quad \text{is } M_b
\]

\[
M_b \quad \text{is the number of BS Tx antennas}
\]

\[
p(u) \text{ in } s_{p(u)}(k) \text{ is equal to } u - j, \text{ where } u \text{ is formed from the UL_Permbase and frame number as described in 8.4.6.2.7.1 and } j \text{ is the CID loop index}
\]
When separability type is 1 in the UL Sounding Command (decimation separability in the sounding waveform), then the Use Same Symbol For Additional Feedback bit specifies whether the additional feedback is sent in the symbol(s) following the allocated sounding symbol, or in the same symbol as the allocated sounding symbol. These two cases are described as follows. If separability type is 1 and the Use Same Symbol For Additional Feedback bit is true, then a number of additional sequential decimation offset indices equal to the number of MS receive antennas is used for the encoded feedback waveform (e.g., if a decimation offset of 1 is used for the UL sounding, then decimation offsets 2 and 3 are the additional decimation offsets used for the additional feedback for a two receive antenna MS). On the \(i\)-th additional decimation offset, the first MS Tx antenna transmits the waveform shown in Equation (74).

\[
Z_i(k) = \beta_u \cdot \sum_{i=1}^{M_b} \hat{H}_{i,j}(k) \cdot s_{p(u)}(k) \cdot \exp\{-j2\pi k(l-1)/\alpha_u\} \tag{74}
\]

where

- \(\hat{H}_{i,j}(k)\) is the estimated DL channel coefficient between the \(l\)-th BS Tx antenna and the \(i\)-th receive MS antenna
- \(\beta_u\) is a scaling to make the average Tx power of the feedback waveform (averaged across all frequency) of \(Z_u(k)\) be one
- \(s_{p(u)}(k)\) is the sounding sequence of 8.4.6.2.7.1
- \(\alpha_u\) is \(M_b\)
- \(M_b\) is the number of BS Tx antennas
- \(p(u)\) in \(s_{p(u)}(k)\) is equal to \(u-j\) where \(u\) is formed from the UL_Permbase and frame number as described in 8.4.6.2.7.1 and \(j\) is the CID loop index

For this type of feedback, the multi-antenna flag in the sounding command should be set to zero so that only the first antenna of the MS transmits the required sounding waveform and only the first antenna of the MS transmits the feedback waveform.

If separability type is 1 and the Use Same Symbol For Additional Feedback bit is false, then every allocated sounding symbol is followed by a number of additional symbols equal to the number of BS antennas. When an MS has a number of receive antennas equal to its number of Tx antennas, then an MS antenna that transmits on subcarrier \(k\) of the sounding symbol shall transmit the DL channel coefficient for the \(i\)-th base antenna to the corresponding MS receive antenna for the \(k\)-th subcarrier on subcarrier \(k\) of the \(i\)-th additional symbol following the allocated sounding symbol. In equation form, the MS that transmits a sounding signal on subcarrier \(k\) of the sounding symbol shall transmit \(\hat{H}_{l,k}\) on the \(l\)-th symbol following the sounding symbol, where \(\hat{H}_{l,k}\) is the DL channel coefficient from the \(l\)-th BS antenna to the corresponding MS receive antenna. When the MS has a single Tx antenna and multiple receive antennas, then the first MS Tx antenna transmits any sounding and feedback requested in the sounding command.

### 8.4.6.2.7.4 Feedback of received pilot coefficients

If the Include Additional Feedback field is set to 0b10, the UL Sounding Command IE() enables the MS to transmit additional feedback based on the DL received pilot signal values in the frequency domain. In this case, a single additional symbol is used to transmit a subset of the received pilot values back to the BS. For the case of a MIMO midamble being used as the source of the received pilots, the midamble received by each SS antenna is decimated in a blockwise fashion, block interlaced to reconstruct the feedback symbol, and sent back on the additional symbol interval. (Blockwise decimation by \(p\) with a block size of \(q\) means to retain one block of \(q\) consecutive samples out of every \(pq\) consecutive samples, and a block decimation offset of \(r\) means that the \(r\)-th block of length \(q\) is the first one to be retained.) For the received MIMO midamble, the blockwise decimation factor \(p\) shall be set equal to the number of SS receive antennas, the
block size $q$ shall be set equal to the number of BS antennas, and the blockwise decimation offset value depends on the receive antenna number of the SS. The blockwise decimation offset for SS receive antenna $m$ ($m = 1, 2, \ldots$) is $m - 1$. Before being transmitted, the power of this additional symbol shall be normalized to the same level as the sounding symbol that precedes it.

### 8.4.6.3 Optional adjacent subcarrier permutations for AMC

A BS may change from the distributed subcarrier permutation, described in 8.4.6.1 and 8.4.6.2, to the adjacent subcarrier permutation when changing from non-AAS to AAS-enabled traffic to support AAS adjacent subcarrier user traffic in the cell. Alternatively, the adjacent subcarrier permutation can be used to take advantage of the structure of the adjacent subcarrier permutation in parts of the DL subframe that are indicated accordingly by the DL-MAP and UL subframe that are indicated accordingly by the UL-MAP. After this change, the BS shall only transmit/receive traffic using the adjacent subcarrier permutation during the allocated period. The BS shall always return to the distributed subcarrier permutation at the beginning of a new DL subframe. Note that an AAS-enabled SS, which does not provision the same permutation (PUSC/FUSC or adjacent) for AAS traffic selected by the BS for this purpose, is not capable of using its AAS capabilities with this BS.

With the adjacent subcarrier permutation, symbol data within a subchannel is assigned to adjacent subcarriers and the pilot and data subcarriers are assigned fixed positions in the frequency domain within an OFDMA symbol. This permutation is the same for both UL and DL. Within each frame, the BS shall indicate the switch to the optional permutation using one of the zone switch IEs specified in 8.4.5.3.3, 8.4.5.3.4, 8.4.5.4.6, and 8.4.5.4.7. To define adjacent subcarrier permutation, a bin, which is a set of nine contiguous subcarriers within an OFDMA symbol, is a basic allocation unit both in DL and UL. A bin structure is shown in Figure 251.

![Figure 251—Bin structure](image)

AMC allocations can be made by two mechanisms—by subchannel index reference in UL-MAP and DL-MAP or by subchannel allocation in a band using HARQ map (defined in 6.3.2.3.38). Each UL or DL zone may include allocations from HARQ and normal map. For regular AMC allocations made by the DL-MAP or UL-MAP, an AMC subchannel of type $N \times M$ (where $N \times M = 6$) is defined as six contiguous bins (a slot consists of $N$ bins by $M$ symbols). The subchannels are numbered from the lowest (0) to the highest frequency so that subchannel $k$ ($k = 0 \rightarrow 192/N$) consists of bins $N \times k$ to $N \times k + N - 1$.

A group of four rows of bins is called a physical band. For band AMC allocations made by HARQ map message, an AMC slot consists of six contiguous bins in a same logical band defined in a Format Configuration IE (6.3.2.3.38.2). There are four types of AMC subchannels, which are different in the collection of six bins in a band. In the first type (default type), the available bins in a band are enumerated by
starting from the lowest bin in the first symbol to the last bin in the symbol, then going to the lowest bin in
the next symbol, and so on. In the first type of AMC subchannel, a slot consists of six consecutive bins in
this enumeration. In the second type of AMC subchannel, a slot is defined as two bins by three symbols. In
the third type, a slot is defined as three bins by two symbols; and in the fourth type, a slot is defined as one
bin by six symbols. In the last three types of AMC subchannel, enumeration of bins in a slot is the same as in
the first type. Table 467 summarizes the parameters of the AAS subcarrier.

</table>

Let the index of the traffic subcarriers be numbered from 0 to 47 within an AMC slot. The index of the first
traffic subcarrier in the first bin is 0, the next one is 1, and so on. The index of the subcarriers increases along
the subcarriers first and then the bin. The \( j \)-th symbol of the 48 symbols where a band AMC slot is allocated
is mapped onto the \( S_{per}(j) - 1 \) -th subcarrier of a slot. \( j \) is [0, 47]. See Equation (75).

\[
S_{per}(j) = \begin{cases} 
P_{per}(j) + off & P_{per}(j) + off \neq 0 \\
off & P_{per}(j) + off = 0
\end{cases}
\]  

(75)

where

\( P_{per}(j) \) is the \( j \)-th element of the left cyclic shifted version of basic sequence \( P_0 \) by per

\( P_0 \) is the basic sequence defined in GF(7²): \{01, 22, 46, 52, 42, 41, 26, 50, 05, 33, 62, 43, 63, 65, 32, 40,
04, 11, 23, 61, 21, 24, 13, 60, 06, 55, 31, 25, 35, 36, 51, 20, 02, 44, 15, 34, 14, 12, 45, 30, 03,
66, 54, 16, 56, 53, 64, 10\} in hepta-notation

\( per = PermBase \mod 48 \)

\( off = \lfloor PermBase/48 \rfloor \mod 49 \). This field is an element of GF(7²).

The addition between two element in GF(7²) is component-wise addition modulo 7 of two representation.
For example, (56) + (34) in GF(7²) = (13).

In the DL, \( PermBase \) shall be set to DL_PermBase specified in preceding STC DL Zone IE; and in the UL,
it shall be set to UL_PermBase specified in preceding UL Zone IE.
8.4.6.3.1 AMC optional permutation

See Table 468, Table 469, and Table 470 for the AMC subcarrier allocations for 1024-FFT, 512-FFT, and 128-FFT, respectively.

</table>
NOTE—A data symbol is a symbol that overlaps with at least one data slot (regardless of whether data are allocated on that slot).

In the region mapped according to HARQ MAP in 6.3.2.3.38, there are four types of AMC subchannels which are different in the collection of six bins in a band. In the first type (default type), the available bins in a band are enumerated by starting from the lowest bin in the first symbol to the last bin in the symbol, then going to the lowest bin in the next symbol, and so on. A subchannel consists of six consecutive bins in this enumeration. The second type is two bins by three symbols, the third type is three bins by two symbols, and
the last type is one bin by six symbols. In the last three types, enumeration of bins in a subchannel is the same as in the first type.

In the region mapped according to normal DL/UL-MAP in 8.4.5.3 and 8.4.5.4, there is only one type of AMC subchannel, which consists of two bins by three symbols.

In all the types, data mapping follows 8.4.3.4 except for region mapped according to 6.3.2.3.38. Slots for DL AMC zone in a region mapped according to 6.3.2.3.38 are allocated along the subchannel index first within a band. The direction of data mapping for DL AMC slots shall be frequency first (across bands when multiple bands are allocated).

Slots for UL AMC zone in a region mapped according to 6.3.2.3.38 are allocated along the symbol index first within a band. The direction of data mapping for UL AMC slots shall be frequency first (across bands when multiple bands are allocated).

**8.4.6.3.2 Band-AMC operation in normal DL/UL-MAP**

This subclause describes the band-AMC operation, which is designed for band-AMC enabled SS using normal DL/UL-MAP. The SS sends the REP-RSP message in an unsolicited fashion to BS to trigger band AMC operation. The triggering conditions are given by TLV encodings in UCD messages. The REP-RSP (see 11.12 for the TLV encodings) includes the CINR measurements of five best bands.

For FFT sizes of 2048 and 1024, the number of Max Logical Bands is defined as 12. For FFT sizes of 512 and 128, the number of Max Logical Bands is the same as the number of physical AMC bands defined in 8.4.6.3. A logical band is a grouping of the physical AMC bands. For example, 12 logical bands for 1024-FFT imply that logical band 0 is composed of AMC bands (0,1), logical band 1 is composed of AMC bands (2,3), and logical band 2 is composed of AMC bands (4,5). In general, if \( K = \text{Max Logical Bands} \), then logical band \( J = [0...(K-1)] \) contains physical bands \( M/K \times J, M/K \times J + 1, ..., M/K \times (J + 1) - 1 \), where \( M \) is the number of physical AMC bands.

The BS acknowledges the trigger by allocating band AMC subchannels. From the next frame when the SS/MS sends the REP-RSP, the SS starts reporting the differential of CINR for four selected bands, and the MS starts reporting the differential of CINR for four or five selected bands (increment: 1 and decrement: 0 with a step of 1 dB) on its allocated fast-feedback channel (CQICH). The band indexes are mapped from LSB to MSB of the CQICH codeword in increasing order. If the BS does not allocate the band AMC subchannels within the specified delay (CQICH band AMC transition delay) in the UCD message, the SS reports the updated average CINR for the allocation of subchannel with distributed subcarrier permutation.

When the BS wants to trigger the transition to band AMC mode and update the CINR reports, it sends the REP-REQ message (see 11.11 for the TLV encodings) or feedback polling IE for type 1101. When the SS receives the message, it replies with REP-RSP or feedback header type 0110. When the BS receives the REP-RSP or feedback header type 0110, it should synchronize the selection of bands reported and their CINRs. Unless the BS allocates subchannels with distributed subcarrier permutation, the SS reports the differential increment/decrement compared to the most up-to-date report in the next CQI reporting frame.

**8.4.6.3.3 AMC support for SDMA**

The pilots in an AMC AAS zone are regarded as part of the allocation, and as such shall be beamformed in a way that is consistent with the transmission of the allocation’s data subcarriers. In an SDMA region, the pilots of each allocation may correspond to a different pilot pattern. A pilot pattern consists of location and polarity. The pilot patterns are depicted in Figure 252. Data subcarriers shall be punctured to obtain patterns #2 and #3. Subcarriers shall only be punctured if there is an allocation associated with the corresponding pattern, as described in the AAS_SDMA_DL_IE(), AAS_SDMA_UL_IE(), PHYMOD_DL_IE(), PHYMOD_UL_IE(), Reduced_AAS_Private_DL-MAP(), or Reduced_AAS_Private_
UL-MAP(). Only MSs that support all four pilot patterns, as indicated by their capability in 11.8.3.5.14, shall be assigned allocations in an SDMA region where pilot patterns #2 and #3 are used. Data subcarriers shall be punctured after constellation mapping in the case of CC encoding, and prior to constellation mapping in the case of CTC encoding. In the latter case, the FEC block shall be truncated to accommodate the punctured subchannel structure, and the data subcarrier enumeration of Equation (75) shall not be applied. Instead, data subcarriers within a slot shall be enumerated starting from the first OFDMA symbol at the data subcarrier that is lowest in frequency, continuing in ascending frequency order throughout the slot’s subcarriers in the same symbol, then going to the next symbol at the subcarrier lowest in frequency, and so on.

8.4.6.4 Optional permutations for PUSC

8.4.6.4.1 Optional permutation for PUSC adjacent subcarrier allocation (PUSC-ASCA)

Two ways to use an adjacent subcarrier allocation for the PUSC mode are given in 8.4.6.4.1.1 and 8.4.6.4.1.2.

8.4.6.4.1.1 Allocation using adjacent clusters

This subclause defines an adjacent subcarrier allocation using adjacent clusters for the PUSC mode.

![Figure 252—Pilot patterns for AAS mode in AMC zone](image_url)
Symbol structure shall use the parameters from Table 442, Table 443, Table 444, and Table 445 (as the regular PUSC); the same cluster structure shall be maintained.

### 8.4.6.4.1.1 Allocation of subcarriers to subchannels

Allocation of subcarriers to subchannels shall be performed in the following manner:

a) Dividing the subcarriers into physical clusters each containing 14 adjacent subcarriers (starting from data subcarrier 0), the number of clusters are defined in Table 442, Table 443, Table 444, and Table 445.

b) Clusters to be used for a specific DL allocation shall be the first $2 \times \text{(Allocated Subchannels)}$ after the first $2 \times \text{(SubchannelOffset)}$.

c) Concatenate the clusters into blocks using the rules from Table 471.
   1) $n$: number of allocated subchannels
   2) $k$: floor ($n / 12$)
   3) $m$: $n$ modulo 12

\[
\begin{array}{|c|c|}
\hline
\text{Number of subchannels} & \text{Clusters concatenated} \\
\hline
n \leq 12 & 1 \text{ block of } 2 \times n \text{ clusters} \\
\hline
n = 12 \times k & k \text{ blocks of 24 clusters} \\
\hline
n > 12, n \neq 12 \times k & (k - 1) \text{ blocks of 24 clusters} \\
& 1 \text{ block of } 2 \times \text{ceil}(m + 12)/2 \text{ clusters} \\
& 1 \text{ block of } 2 \times \text{floor}(m + 12)/2 \text{ clusters} \\
\hline
\end{array}
\]

d) Per block, remove from the clusters associated with the section the pilot carriers, take the remaining data subcarriers and using the same procedure described in 8.4.6.1.2.2.2 (with the parameter $N_{subcarriers} = 24$, PermutationBase taken from Table 472 and Cell_Id as defined in message PUSC_Directed_MIMO_Alloc_IE) partition the subcarriers into subchannels containing 24 data subcarriers in each OFDMA symbol.

### Table 472—Cluster permutation base

\[
\begin{array}{|c|c|c|}
\hline
\text{Permutation ID} & \text{Number of clusters in the section} & \text{Permutation Base} \\
\hline
12 & 24 & [6,9,4,8,10,11,5,2,7,3,1,0] \\
11 & 22 & [6,9,2,8,10,5,0,4,3,1,7] \\
10 & 20 & [6,4,1,2,9,3,5,8,7,0] \\
9 & 18 & [7,4,0,2,1,5,3,8,6] \\
8 & 16 & [7,4,0,2,1,5,3,6] \\
7 & 14 & [2,1,5,3,4,6,0] \\
6 & 12 & [2,1,5,3,4,0] \\
5 & 10 & [4,2,3,1,0] \\
4 & 8 & [2,3,1,0] \\
\hline
\end{array}
\]
8.4.6.4.1.2 Allocation using distributed clusters

This subclause defines an adjacent subcarrier allocation using distributed clusters for the PUSC mode.

Symbol structure shall use the parameters from Table 434 (as the regular PUSC); the same cluster structure shall be maintained.

8.4.6.4.1.2.1 Allocation of subcarriers to subchannels

Allocation of subcarriers to subchannels shall be performed in the following manner:

a) Dividing the subcarriers into 120 physical clusters containing 14 adjunct subcarriers each (starting from carrier 0).

b) Renumbering the physical clusters into logical clusters using the following formula:
LogicalCluster = RenumberingSequence((PhysicalCluster + 13 × IDcell) mod 120).

c) Dividing the clusters into six major groups (number of clusters per Major group is set using parameters from Table 434).

d) Allocating carriers to subchannel in each major group depends on the specific allocation performed. Per major group determine the number of clusters which are to be used in the specific allocation (clusters to be used for a specific DL allocation shall be the first 2 × (Allocated Subchannels) after the first 2 × (SubchannelOffset)), determine the number of clusters to be used in every major group. Per major group (which includes allocated clusters) remove from the associated clusters the pilot carriers, take the remaining data subcarriers and using the same procedure described in 8.4.6.1.2.2.2 (with the parameter Nsubcarriers = 24, PermutationBase taken from Table 472 and Cell_Id as defined in message PUSC Directed MIMO Allocation IE) partition the subcarriers into subchannels containing 24 data subcarriers in each OFDMA symbol.

8.4.7 OFDMA ranging

A ranging channel is composed of one or more groups of six adjacent subchannels, using the symbol structure defined in 8.4.6.2.1, where the groups are defined starting from the first subchannel. Optionally, ranging channel can be composed of one or more groups of eight adjacent subchannels using the symbol structure defined in 8.4.6.2.5 or 8.4.6.3. Subchannels are considered adjacent if they have successive logical subchannel numbers. The indices of the subchannels that compose the ranging channel are specified in the UL-MAP message. Users are allowed to collide on this ranging channel. To effect a ranging transmission, each user randomly chooses one ranging code from a bank of specified binary codes. These codes are then BPSK modulated onto the subcarriers in the ranging channel, 1 bit per subcarrier (subcarriers used for ranging shall be modulated with the waveform specified in 8.4.7.1 or 8.4.7.2 and are not restricted to any time grid specified for the data subchannels).

For some circumstances, such as trying network reentry to another new BS in the drop situation, location update in idle mode, or fast call recovery, the MS may need additional UL resources for RNG-REQ because...
of the HMAC/CMAC tuple. The MS shall use the HO ranging code if the RNG-REQ requires an HMAC/CMAC tuple. The BS receiving an HO ranging code shall allocate more bandwidth to the MS, i.e., enough to send RNG-REQ with HMAC tuple.

For the 128-FFT and 512-FFT, the BS may allocate less than 6 (or 8 in case of optional PUSC or AMC) subchannels for a ranging or BR allocation. In this case, the MS shall produce the ranging code as defined below (as if 6/8 subchannels were allocated), but modulate only the tones in the subchannels allocated (so that the last bits of the ranging code are not transmitted). For the 512-FFT, the minimum allocation shall be 5 subchannels for PUSC (or 8 for the optional PUSC or AMC). In case of 512-FFT, the minimum allocation of 5 subchannels in UL PUSC zone shall be restricted to the case of segmented PUSC using UL allocated subchannels bitmap, where the BS shall allocate ranging or BR allocation of minimum 5 subchannels for the segment that has only 5 subchannels. For other cases, BS shall allocate ranging or BR allocation only as a multiple of 6 subchannels (8 subchannels in case of optional PUSC or AMC). That is, BS shall only allocate ranging size of 6 or 12 subchannels (8 or 16 or 24 in case of optional PUSC or AMC).

8.4.7.1 Initial ranging and HO ranging transmissions

The initial ranging codes shall be used for initial network entry and association. HO ranging codes shall be used for ranging against a Target BS during HO. An initial ranging transmission shall be performed during two or four consecutive symbols. The same ranging code is transmitted on the ranging channel during each symbol, with no phase discontinuity between the two symbols. A time-domain illustration of the initial ranging or HO ranging transmission is shown in Figure 253.

![Figure 253—Initial ranging or HO ranging transmission for OFDMA](image)

The transmitted signal is according to 8.4.2.5, Equation (56), except that $0 \leq t \leq 2T_s$. 
The BS can allocate two consecutive initial ranging or HO ranging slots; onto those slots, the MS shall transmit the two consecutive initial ranging or HO ranging codes (starting code shall always be a multiple of 2), as illustrated in Figure 254.

![Figure 254—Initial ranging or HO ranging transmission for OFDMA, using two consecutive initial ranging or HO ranging codes](image)

**Figure 254**—Initial ranging or HO ranging transmission for OFDMA, using two consecutive initial ranging or HO ranging codes

### 8.4.7.2 Periodic ranging and BR transmissions

Periodic ranging transmissions are sent periodically for system periodic ranging. BR transmissions are for requesting UL allocations from the BS.

These transmissions shall be sent only by SS that have already synchronized to the system.

To perform either a periodic ranging or BR transmission, the SS can send a transmission in one of the following ways:

a) Modulate one ranging code on the ranging subchannel for a period of one OFDMA symbol. Ranging subchannels are dynamically allocated by the MAC and indicated in the UL-MAP. A time-domain illustration of the periodic ranging or BR transmission is shown in Figure 255.

![Figure 255—Periodic ranging or BR transmission for OFDMA using one code](image)

**Figure 255**—Periodic ranging or BR transmission for OFDMA using one code
b) Modulating three consecutive ranging codes (starting code shall always be a multiple of three) on
the ranging subchannel for a period of three OFDMA symbols (one code per symbol). Ranging
subchannels are dynamically allocated by the MAC and indicated in the UL-MAP. A time-domain
illustration of the periodic ranging or BR transmission is shown in Figure 256.

![Figure 256—Periodic ranging or BR transmission for OFDMA using
three consecutive codes](image)

### 8.4.7.3 Ranging codes

The binary codes are the pseudonoise codes produced by the PRBS described in Figure 257, which
implements the polynomial generator \( 1 + X^4 + X^7 + X^{15} \). The PRBS generator shall be initialized by the
seed \( b_{14..b0} = 0,0,1,0,1,0,1,1,s_0,s_1,s_2,s_3,s_4,s_5,s_6 \), where \( s_6 \) is the LSB of the PRBS seed, and
\( s_6:s_0 = UL\_PermBase \), where \( s_6 \) is the MSB of the UL\_PermBase.

![Figure 257—PRBS generator for ranging code generation](image)

The binary ranging codes are subsequences of the pseudonoise sequence appearing at its output \( C_k \). The
length of each ranging code is 144 bits. These bits are used to modulate the subcarriers in a group of six
(eight for the permutation defined in 8.4.6.2.5 or 8.4.6.3) adjacent subchannels, where subchannels are
considered adjacent if they have successive logical subchannel numbers. The bits are mapped to the
subcarriers in increasing frequency order of the subcarriers so that the lowest indexed bit modulates the
subcarrier with the lowest frequency index and the highest indexed bit modulates the subcarrier with the
highest frequency index. The index of the lowest numbered subchannel in the six (eight for the permutation
defined in 8.4.6.2.5 or 8.4.6.3) shall be an integer multiple of six (eight for the permutation defined in
8.4.6.2.5 or 8.4.6.3). The six (eight for the permutation defined in 8.4.6.2.5 or 8.4.6.3) subchannels are
called a ranging subchannel. The ranging subchannel is referenced in the ranging and BR messages by the index of lowest numbered subchannel.

For example, the first 144-bit code, obtained by clocking the PN generator as specified and by setting $UL\_PermBase = 0$, shall be 00110000010001... The next ranging code is produced by taking the output of the 145th to 288th clock of the PRBS generator, etc.

The number of available codes is 256, numbered 0..255. Each BS uses a subgroup of these codes, where the subgroup is defined by a number $S$, $0 \leq S \leq 255$. The group of codes shall be between $S$ and $((S + O + N + M + L) \mod 256)$.

- The first $N$ codes produced are for initial ranging. Clock the PRBS generator $144 \times (S \mod 256)$ times to $144 \times ((S + N) \mod 256) – 1$ times.
- The next $M$ codes produced are for periodic ranging. Clock the PRBS generator $144 \times ((N + S) \mod 256)$ times to $144 \times ((N + M + S) \mod 256) – 1$ times.
- The next $L$ codes produced are for BRs. Clock the PRBS generator $144 \times ((N + M + S) \mod 256)$ times to $144 \times ((N + M + L + S) \mod 256) – 1$ times.
- The next $O$ codes produced are for HO ranging. Clock the PRBS generator $144 \times ((N + M + L + O) \mod 256)$ times to $144 \times ((N + M + L + O + S) \mod 256) – 1$ times.

The BS can separate colliding codes and extract timing (ranging) information and power. In the process of user code detection, the BS gets the Channel Impulse Response (CIR) of the code, thus acquiring for the BS vast information about the user channel and condition. The time (ranging) and power measurements allow the system to compensate for the near/far user problems and the propagation delay caused by large cells.

**8.4.7.4 Ranging and BR opportunity size**

For CDMA ranging and BR, the ranging opportunity size is the number of symbols required to transmit the appropriate ranging/BR code (1, 2, 3, or 4 symbols), and is denoted $N_1$. $N_2$ denotes the number of subchannels required to transmit a ranging code (6 or 8; see 8.4.7.3). In each ranging/BR allocation, the opportunity size ($N_1$) is fixed and conveyed by the corresponding UL-MAP IE that defines the allocation.

The ranging allocation is subdivided into slots of $N_1$ OFDMA symbols by $N_2$ subchannels, in a time first order, i.e., the first opportunity begins on the first symbol of the first subchannel of the ranging allocation, the next opportunities appear in ascending order in the same subchannel, until the end of the ranging/BR allocation (or until there are less than $N_1$ symbols in the current subchannel), and then the number of subchannel is incremented by $N_2$. The ranging allocation is not required to be a whole multiple of $N_1$ symbols, so a gap may be formed (that can be used to mitigate interference between ranging and data transmissions). Each CDMA code shall be transmitted at the beginning of the corresponding slot. See Figure 258.
8.4.8 Space-time coding (STC) (optional)

8.4.8.1 STC using two antennas

STC (in some cases also termed STTD) or FHDC may be used on the DL to provide higher order (space) Tx diversity (see Alamouti [B1]).

There are two Tx antennas on the BS side and one reception antenna on the SS side. This scheme requires multiple input single output channel estimation. Decoding is very similar to maximum ratio combining.

Figure 259 shows Tx diversity insertion into the OFDMA chain. Each Tx antenna has its own OFDMA chain, but they have the same Local Oscillator for synchronization purposes.

Both antennas transmit two different OFDMA data symbols in the same time. Time domain (Space-Time) or Frequency domain (Space-Frequency) repetition is used.
This mode of operation allows better performance with higher complexity in the receiver. The mode of operation introduced in the sequel defines a combined operation of the Tx diversity using PUSC or FUSC in the DL only. The current PUSC mandatory mode of operation allows the splitting of the available Subchannels into three segments, each transmitting some (or all) of the subchannels as allocated by the FCH. The Tx diversity mode of operation shall be used in a combined way with the mandatory mode of operation; this is performed by allocating subchannels to either of the modes of operation.

The allocation of subchannels to STC operation shall be done by allocating one or more groups of subchannels as defined in 8.4.4.5.

The regular subchannel and preamble transmission in the DL shall be performed from only one antenna (Antenna 0) (unless CDD is employed, see 8.4.8.7) while the Tx diversity subchannels transmission shall be performed from both antennas obeying the formulas in 8.4.8.1.2.1.

8.4.8.1.1 Multiple-input, single-output channel estimation and synchronization

Both antennas transmit in the same time, and they share the same Local Oscillator. Thus, the received signal has exactly the same autocorrelation properties as for a single antenna. Time and frequency coarse and fine estimation can be performed in the same way as for a single antenna. The scheme requires multiple-input, single-output channel estimation, which is allowed by splitting some pilots between the 2 Tx antennas, as described in 8.4.8.1.2.1.

8.4.8.1.2 STC using two antennas

8.4.8.1.2.1 STC encoding

The 2-antenna rate 1 scheme is a basic STC scheme, enabled by Matrix A as defined in 8.4.8.1.4. Other STC schemes are defined in a matrix notation in 8.4.8.1.4. The basic scheme (Alamouti [B1]) transmits two complex symbols $s_1$ and $s_2$, using the multiple-input, single-output channel (two Tx, one Rx) with channel vector values $h_0$ (for antenna 0) and $h_1$ (for antenna 1).

First channel use: Antenna 0 transmits $s_1$, antenna 1 transmits $s_2$.

Second channel use: Antenna 0 transmits $-s_2^*$, antenna 1 transmits $s_1^*$.

Receiver gets $r_0$ (first channel use) and $r_1$ (second channel use) and computes $s_1$ and $s_2$ estimates:

$$\hat{s}_1 = h_0^* \times r_0 + h_1 \times r_1^*$$

(76)

$$\hat{s}_2 = h_1^* \times r_0 - h_0 \times r_1^*$$

(77)

These estimates benefit from second order diversity as in the 1Tx-2Rx Maximum Ratio Combining scheme.

STC rate 1 encoding shall be performed after constellation mapping and before subcarrier randomization defined in 8.4.9.4.1. Symbols $s_1$ and $s_2$ represent two subcarriers at the same frequency in two consecutive OFDMA symbols (each OFDMA subcarrier is referred to as a channel use). The STC rate 1 coding is done on all data subcarriers that belong to an STC-coded burst in the two OFDMA symbols. Pilot subcarriers are not encoded and are transmitted from either antenna 0 or antenna 1.

The STC transmission may be used both in a PUSC and FUSC configurations.
8.4.8.1.2.1.1 STC using 2 antennas in PUSC

In PUSC, the data allocation to cluster is changed (Figure 260) to accommodate two antennas transmission with the same estimation capabilities, each cluster shall be transmitted twice from each antenna.

Figure 260 replaces Figure 247 in the definition of PUSC permutation when STC is enabled. The pilot locations change in period of four symbols.

Symbols are counted from the beginning of the current zone. The first symbol in the zone is even. STC encoding is done on each pair of symbols $2n, 2n+1$ ($n = 0, 1, ...$).

Table 473 shows an STC data mapping example for the DL PUSC using vertical encoding as the result of mapping of QAM symbols (see 8.4.3.4) followed by MIMO encoding. Each row is subcarrier-in-subchannel, and each column is a symbol. $s_0..s_{47}$ denote first slot out of the FEC, $s_{48..s_{95}}$ denote second slot. The figure is in logical subcarriers (subcarrier in subchannel) over symbols (before DL PUSC permutation).

---

8.4.8.1.2.1.2 STC using two antennas in FUSC

In FUSC, the pilots within the symbols shall be divided between the antennas. Antenna 0 uses VariableSet#0 and ConstantSet#0 for even symbols while antenna 1 uses VariableSet#1 and ConstantSet#1 for even symbols. Antenna 0 uses VariableSet#1 and ConstantSet#0 for odd symbols while antenna 1 uses VariableSet#0 and ConstantSet#1 for odd symbols (symbol counting starts at the starting point of the relevant STC zone), defined in 8.4.6.1.2.2. In STC transmission, the \( FUSC\_SymbolNumber \) in Equation (62) is replaced with \( \text{floor}(FUSC\_SymbolNumber/2) \) so that variable pilots shall move every second symbol. The transmission of the data shall be performed in pairs of symbols as illustrated in Figure 261.

**Table 473—STC mapping example for DL PUSC (continued)**

**Figure 261—STC usage with FUSC**

[Diagram of STC usage with FUSC]
8.4.8.1.2.1.3 STC data mapping

In the STC zone, for spatial multiplexing, the mapping of modulated data after channel encoding to MIMO streams depends on the type of encoding (horizontal or vertical encoding).

For vertical encoding (num_layer = 1), the number of data slots used by the FEC encoder equals R times the number of physical slots allocated in the map, where R is the space time coding rate and equals the number of streams in case of spatial multiplexing. Denote the number of allocated physical slots by D (duration). The $D \times R$ data slots shall be encoded, including splitting the data into FEC blocks according to the concatenation rule, randomization, encoding, interleaving, and repetition, as specified in 8.4.9, and shall be mapped to QAM symbols. Then, the resulting QAM symbols shall be mapped in stream-first order into R streams as described in 8.4.8.

For example, if the rate is $R = 2$, and no precoding is used, then the 48 QAM symbols of the first data slot are mapped to the first 24 subcarriers of the first physical slot (in antenna first order, so that the even QAM symbols are mapped to antenna 0 and the odd QAM symbols to antenna 1), the next 48 symbols are mapped to subcarriers 25..47 of the first physical slot. The mapping continues to the second physical slot, and so on.

For horizontal encoding with rate $T$, (num_layer=$T$), the number of data slots used by the FEC encoder equals the number of physical slots allocated in the map, and $T$ different bursts are encoded. Each burst is allocated to a stream.

8.4.8.1.2.2 STC decoding

The receiver waits for two symbols and combines them on a subcarrier basis according to Equation (76) and Equation (77) in 8.4.8.1.2.1.

8.4.8.1.3 Frequency hopping diversity coding (FHDC)

This scheme (as for STC) transmits two complex symbols, $s_1$ and $s_2$, using the multiple input single output channel (two Tx, one Rx). Allocation of subchannels for FHDC transmission shall be even numbered in the same OFDMA symbol, and the first subchannel shall have an even logical index.

The transmission is based on transmitting the FHDC allocated subchannels from both antennas in the following format:

- Antenna 0 transmits mapped carriers for subchannel $X$ ($S_1$) onto subchannel $X$ and mapped carriers for subchannel $X + 1$ ($S_2$) onto subchannel $X + 1$
- Antenna 1 transmits ($-S_2^*$) onto subchannel $X$ and ($S_1^*$) onto subchannel $X + 1$

Receiver gets $r_0$ (reception of subchannel $X$) and $r_1$ (reception of subchannel $X + 1$), and the user shall extract signals $S_1$, $S_2$:

$$r_0 = h_{x,0} \cdot S_1 - h_{x,1} \cdot S_2$$
$$r_1 = h_{x+1,0} \cdot S_2 + h_{x+1,1} \cdot S_1^*$$

These estimates benefit from second order diversity as in the 1Tx-2Rx Maximum Ratio Combining scheme. The DL preamble shall be transmitted for the duration of one OFDMA symbol from antenna #0 as shown in Figure 262, and subchannels used for FHDC are transmitted in adjunct pairs of subchannels.

The same data/pilot subcarrier structure as defined for the STC mode shall be used in the FHDC mode.
8.4.8.1.4 STC/FHDC configurations

Two transmission formats are allowed for the two antenna configuration, each format has its own capacity/diversity tradeoffs. The following matrices define the transmission format with the row index indicating the antenna number and column index indicating the OFDMA symbol. The entries define the transmission from a subchannel used for this transmission configuration (the same operation is repeated for all subchannels used in this format).

Transmission format A uses Matrix A (space time coding rate = 1, as explained in 8.4.8.1.2 and 8.4.8.1.3):

\[
A = \begin{bmatrix}
S_1 & -(S_2)^* \\
S_2 & (S_1)^*
\end{bmatrix}
\]  
(79)

Transmission format B uses Matrix B (space time coding rate = 2):

\[
B = \begin{bmatrix}
S_1 \\
S_2
\end{bmatrix}
\]  
(80)

8.4.8.1.5 UL using STC

A user-supporting transmission using STC configuration in the UL shall use a modified UL tile. The 2-Tx diversity data (STTD mode) or 2-Tx spatial multiplexing (SM mode) data that can be mapped onto each subcarrier. The mandatory tile shall be modified to accommodate those configurations.

In STTD mode, the tiles shall be allocated to subchannels and the data subcarriers enumerated as defined in 8.4.6.2. The pilots in each tile shall be split between the two antennas, and the data subcarriers shall be encoded in pairs after constellation mapping, as depicted in Figure 263. The data subcarriers transmitted from antenna #0 follow the original mapping defined in 8.4.6.2.
Two single Tx antenna SSs can perform collaborative spatial multiplexing onto the same subcarrier. In this case, one SS shall use the UL tile with pattern A, and the other SS shall use the UL tile with pattern B. The pilot patterns are depicted in Figure 263. Tx data shall be coded, interleaved, modulated, and mapped to time/frequency as in the non-MIMO case. A single user having two antennas may do UL spatial multiplexing either using horizontal coding or vertical coding. For horizontal coding, two bursts are first individually modulated and then transmitted one per antenna (first burst on antenna #0, the second burst on antenna #1). For vertical coding, a single burst is modulated and then transmitted according to the mapping order defined in 8.4.3.4 with the modification that on each subchannel, two consecutive slots are mapped instead of a single slot. The first slot of each slot pair is transmitted using antenna #0, while the second slot is transmitted using antenna #1.

To do spatial multiplexing with either vertical or horizontal coding, a subscriber needs to signal both its antennas. In order to signal both antennas, the subscriber uses both pilot patterns A and B. Antenna #0 shall be signaled using pattern A, and antenna #1 using pattern B. For non-MIMO transmissions, only antenna #0 shall be used.

Two single Tx antenna SSs can perform collaborative spatial multiplexing onto the same subchannel. In this case, the one SS should use the UL tile with pilot pattern A, and the other SS should use the UL tile with pilot pattern B. Also, two dual Tx antenna SSs can perform collaborative spatial multiplexing onto the same subchannel. In this case, the one SS should use the UL tile with the pilot pattern A, B; and the other SS should use the UL tile with the pilot pattern C, D through MIMO UL Enhanced IE. Pilot patterns are illustrated in the Figure 263 and Figure 264.
8.4.8.1.6 STC of two antennas using directivity through four antennas

The STC scheme for two antennas may be enhanced by using four antennas at the transmission site. Two antennas are now being used in order to transmit each symbol (the first antenna transmits the signal as defined in 8.4.8.1.2 and 8.4.8.1.3, and the second transmits the same signal with a complex multiplication factor). The BS may change the antenna weights using feedback from the user as described in 8.4.11.2. This scheme is presented in Figure 265.

This method does not change the channel estimation process of the user; therefore, this scheme could be implemented without any changes made to the Tx diversity user.

8.4.8.2 STC for four antennas

The STC schemes could be further enhanced by using four antennas at the transmission site. This configuration could be only used using STC encoding with PUSC or FUSC scheme.
8.4.8.2.1 STC for four antennas using PUSC

For this configuration, the basic cluster structure is changed (as indicated in Figure 266) to accommodate the transmission from four antennas. (Pilots for antennas #2/3 override data subcarriers. The data puncturing for CC or the data truncation for CTC shall be performed after STC encoding and before IFFT packet mapping.)

![Cluster structure for STC PUSC using four antennas](image)

8.4.8.2.2 STC for four antennas using FUSC

For the FUSC configuration, the pilots embedded within the symbol shall be further divided. The pilots shall be transmitted with a structure including four time symbols (repeating itself every four symbols) as follows:

- Even symbols: antenna 0 uses VariableSet#0 and ConstantSet#0, antenna 1 uses VariableSet#1 and ConstantSet#1, antenna 2 uses indices of (VariableSet#0+1), and antenna 3 uses indices of (VariableSet#1+1)
- Odd symbols: antenna 0 uses VariableSet#1, antenna 1 uses VariableSet#0, antenna 2 uses indices of (VariableSet#1+1) and (ConstantSet#0), and antenna 3 uses indices of (VariableSet#0+1) and (Constant-Set#1)

In STC transmission the \( FUSC\_SymbolNumber \) in Equation (62) is replaced with \( \text{floor}(FUSC\_SymbolNumber/2) \) so that variable pilots shall move every second symbol. The FUSC permutation is performed on the data subcarriers remaining after allocating the pilots for antennas 0,1 and the constant pilots. The data subcarriers that overlap with variable pilots allocated to antennas 2,3 are replaced with pilots. The data puncturing for CC or the data truncation for CTC shall be performed after STC encoding and before IFFT subcarrier mapping. See Figure 267.

8.4.8.2.3 STC configurations

Several transmission formats are allowed for this configuration. Each format has its own capacity/diversity tradeoffs.
The following matrices define the transmission format with the row index indicating the antenna number and column index indicating the OFDMA symbol. The entries define the transmission from a subchannel used for this transmission configuration (the same operation is repeated for all subchannels used in this format).

Transmission format A uses Matrix A (space time coding rate = 1):

\[
A = \begin{bmatrix}
S_1 - (S_2)^* & 0 & 0 \\
S_2 (S_1)^* & 0 & 0 \\
0 & 0 & S_3 - (S_4)^* \\
0 & 0 & S_4 (S_3)^*
\end{bmatrix}
\]  \hspace{1cm} (81)

Transmission format B uses Matrix B (space time coding rate = 2):

\[
B = \begin{bmatrix}
S_1 - (S_2)^* & S_5 - (S_7)^* \\
S_2 (S_1)^* & S_6 - (S_8)^* \\
S_3 - (S_4)^* & S_7 (S_5)^* \\
S_4 (S_3)^* & S_8 (S_6)^*
\end{bmatrix}
\]  \hspace{1cm} (82)

Transmission format C uses Matrix C (space time coding rate = 4):

\[
C = \begin{bmatrix}
S_1 \\
S_2 \\
S_3 \\
S_4
\end{bmatrix}
\]  \hspace{1cm} (83)
8.4.8.2.4 MIMO MDHO-based macro-diversity transmission

An MDHO zone may be defined by the OFDMA DL STC Zone IE by setting the IDcell = 0. For the MDHO-BSs joint transmission, for the STC capable MS, the total $N$ antennas of MDHO-BSs constitute an antenna pool. A predetermined antenna selection formula can be used. The MIMO Tx formats are specified in 8.4.8.1.4 for 2-Tx-antenna case and 8.4.8.2.3 for 4-Tx-antenna case. The MIMO pilot transmission is 2-antenna transmission for PUSC and FUSC and shall follow the arrangement of the Figure 260 and 8.4.8.1.2.1.2, respectively (see Figure 209 for the optional FUSC and AMC permutations). The MIMO pilot transmission is 4-antenna transmission for PUSC and FUSC shall follow the arrangement of the Figure 266 and 8.4.8.2.2, respectively (see Figure 231 for the optional FUSC and AMC permutations). The unselected antennas are set to the null transmission.

MS shall demodulate signal in the same procedure as in non-MDHO mode if it does not receive MIMO in Another BS IE() or Macro MIMO DL Basic IE(). The same data are transmitted from multiple BSs in the same data regions. MS performs RF or diversity combining.

MS shall perform soft data combining when it receives MIMO in Another BS IE(). In this case, the same data are transmitted in the same or different data region.

The MS shall demodulate signal in the same procedure as in non-MDHO mode, then it shall perform soft combining for those data regions with the same packet index when it receives Macro MIMO DL Basic IE(). This scheme benefits from combination of RF, diversity combining, and soft data combining.

8.4.8.3 STC for the optional zones in the DL

Three optional zones for the DL—the optional FUSC, optional AMC, and the optional PUSC-ASCA zones—are described in 8.4.6.1.2.3, 8.4.6.3, and 8.4.6.4.1, respectively. STC may be used to improve system performance for these zones and an example of Tx diversity (TD) with multiple transmitters and multiple receivers is shown in Figure 268.

In Figure 268, the STC encoder operates on input data symbols sequentially and distributes the antenna specific data symbols to each antenna path. The block of subcarrier mapping and PRBS function denotes data truncation or puncturing, if needed, pilot insertion, IFFT input packing and each subcarrier multiplied by the factor $2 \times (1/2 - w_k)$ according to the subcarrier index $k$ in 8.4.9.4.1. The data truncation for CTC or the puncturing of CC encoder shall be required for 3 Tx and 4 Tx BS for the optional AMC and the optional FUSC zones in the DL, and required for 2 Tx for the optional PUSC in the UL.

This figure also represents the usage of Matrix B with vertical encoding for 3 or 4 Tx BS.
For the usage of Matrix B with horizontal encoding for 3 or 4 Tx BS, an exemplary figure is shown in Figure 269.

Figure 270 illustrates the usage of Matrix C with vertical encoding. The modulated symbols are distributed sequentially from the top to the bottom output paths.

A “layer” is defined as an information path fed to the STC encoder as an input, and a “Stream” is defined as each information path encoded by the STC encoder that is passed to subcarrier mapping and sent through one antenna, or passed to the beamformer. Therefore, the number of layers in a system with vertical encoding is one, but in case of horizontal encoding it depends on the number of encoding/modulation paths.
The number of streams in both vertical and horizontal encoding systems is the same as the number of output paths of the STC encoder.

Figure 270—Example of Matrix C with vertical encoding for 2, 3, or 4 Tx BS for optional zones in DL

An exemplary figure for Matrix C with horizontal encoding is provided in Figure 271.

Figure 271—Example of Matrix C with horizontal encoding for 2, 3 or 4 Tx BS for optional zones in DL
8.4.8.3.1 Symbol structure for optional AMC and optional FUSC

8.4.8.3.1.1 Allocation of pilot subcarriers

The two-stream pilot pattern is defined in Figure 272.

Pilot Location for Antenna #0 = $18k + 9 \cdot \text{mod}(m,2) + 3\lfloor m/2 \rfloor \cdot 2 \text{ mod } 3 + 1$

Pilot Location for Antenna #1 = $18k + 9 \cdot \text{mod}(m+1,2) + 3\lfloor m/2 \rfloor \cdot 2 \text{ mod } 3 + 1$

for $m = \text{[symbol index]}$, symbol index 0 is the first symbol (except midamble) in which the STC Zone is applied, $k$ is the subchannel index.

In other words, symbol index shall be reset to 0 when a new STC Zone is applied.

For 3-antenna BS, pilot allocation pattern shall first be changed as in the 2-antenna BS case, and then the neighboring two subcarriers shall be further allocated as pilots. This is shown in Figure 273.
For 4-antenna BS, pilot pattern shall first be changed as in the 2-antenna BS case, and then the neighboring two subcarriers shall be further punctured for antenna 2 and 3 as is shown in Figure 274.

In other words, symbol index shall be reset to 0 when a new STC Zone is applied.
8.4.8.3.1.2 Allocation of data subchannels

8.4.8.3.1.2.1 STC Mapping for optional AMC permutation

For the optional AMC permutation in STC zone, 2x3 (2 bins by 3 symbols) format is used. The subcarrier permutation represented by Equation (75) in 8.4.6.3 shall not be applied for the optional AMC permutation within STC zones (where STC field in STC DL Zone IE is not equal to 0b00). The pilot pattern of 8.4.8.3.1.1 shall be used.

For 2-antenna Matrix A in 8.4.8.3.3 the bursts are required to have six symbol granularity and begin on a six symbol boundary. In the first stage the data is first mapped frequency-first to each 2x3 slot, and frequency-first over the slots of the allocation as depicted in Figure 220. Then at the second stage Matrix A encoding is performed over each pair of QAM symbols which were assigned to the same subcarrier index over two symbols. The symbol pairs for Matrix A encoding numbered from the beginning of the STC zone are 2n, 2n+1 (n ≥ 0). Note that since the slot duration does not divide by 2, the Matrix A encoding involves QAM symbols potentially belonging to different slots. An illustration of the mapping rule for the antenna #0 is shown in Figure 275, assuming 2 Tx with Matrix A for a block of two slots in a single subchannel with a 2x3 AMC slot. Figure 276 illustrates as an example encoding of 192 QAM symbols into over two subchannels and six symbols for Matrix A.

Figure 275—Data mapping example in the optional AMC Zone with 2 Tx antenna and Matrix A
For 2-antenna vertically encoded Matrix B in the optional AMC permutation, modulated data symbols shall be sequentially mapped for two Tx antennas along the subcarriers of the first symbol in antenna-first order. The mapping inside the AMC slot continues in an ascending manner in subcarriers first and then proceeds to the next symbol in time. An illustration of the mapping rule for the antenna #0 is shown in Figure 277, assuming 2 Tx with vertically encoded Matrix B for a block of 2 slots in one subchannel. Figure 277 also shows the mapping rule for 2-antenna horizontally encoded Matrix B in the optional AMC permutation, where each encoded stream is separately mapped to the corresponding antenna.

For a 3- or 4-antenna Matrix A and Matrix B in 8.4.8.3.4 and 8.4.8.3.5, STC encoded data symbols shall be mapped at two adjacent subcarriers over two OFDMA symbols. When the subcarrier pair (over two symbols) at frequency \( k+1 \) is allocated to pilots for antenna #0 or #1 and the pair at frequency \( k+2 \) is allocated to pilots for antenna #2 or #3, then the pair at frequency \( k+3 \) shall be jointly encoded with the pair at frequency \( k \). This is illustrated in Figure 278, where blocks of 2 convolutional coded (CC) slots and
convolutional turbo coded (CTC) slots are separately shown for an allocation of 1 subchannels by 6 symbols. The mapping starts at the lowest numbered subcarriers of the lowest slot and continues in an ascending manner in subchannels first and then proceeds to the next two symbols in time.

For a 3- and 4-antenna vertically/horizontally encoded Matrix C in the optional AMC permutation, the same mapping rule for 2-antenna vertically/horizontally encoded Matrix B shall be applied on the same frequency-time block with the 3- or 4-antenna pilot pattern.

8.4.8.3.1.2.2 STC Mapping for optional FUSC permutation

For the optional FUSC permutation in STC zone, the data subchannels shall be allocated for two consecutive OFDMA symbols. For a 2-antenna Matrix A in 8.4.8.3.3, STC encoded data symbols shall be time mapped over two OFDMA symbols. The mapping starts at the lowest numbered subcarriers of lowest slot and continues in an ascending manner in subchannels first and then, if needed, proceeds to the next two symbols in time.

For a 2-antenna vertically encoded Matrix B in 8.4.8.3.3 for the optional FUSC permutation, the data subchannels shall be allocated for two consecutive OFDMA symbols and the modulated data symbols shall be sequentially mapped for two Tx antennas along the subcarriers in the symbol. The mapping continues in an ascending manner in subchannels first and then proceeds to the next symbol in time. For a 2-antenna horizontally encoded Matrix B in 8.4.8.3.3 each encoded stream is separately mapped to the corresponding antenna.
For a 3- and 4-antenna Matrix A and Matrix B in 8.4.8.3.3 and 8.4.8.3.4 for the optional FUSC permutation, STC encoded data symbols shall be mapped at two logical subcarriers over two OFDMA symbols. When the subcarrier pair (over two symbols) at logical frequency $k+1$ is allocated to pilots for antenna #0 or #1 and the pair at logical frequency $k+2$ is allocated to pilots for antenna #2 or #3, then the pair at logical frequency $k+3$ shall be jointly encoded with the pair at logical frequency $k$. The mapping starts at the lowest numbered subcarriers of the lowest slot and continues in an ascending manner in subchannels first and then proceeds to the next two symbols in time if needed. Data puncturing for CC or truncation for CTC shall be performed in a similar manner as in the optional AMC zone.

For 3- and 4-antenna vertically/horizontally encoded Matrix C in the optional FUSC permutation, the same mapping rule for 2-antenna vertically/horizontally encoded Matrix B shall be applied on the same frequency-time block with the 3- or 4-antenna pilot pattern.

A mapping example of a DL burst for the optional FUSC using 4-antenna transmission is provided in the following:

Parameters are as follows:

- IDcell = 1
- Symbol index $m = 0$ (first symbol in STC zone)
- Subchannel index = 0
- Number of subchannels = 1
- 1024-FFT

The indices of 48 data subcarriers in subchannel #0 for the optional FUSC are as follows:
If Convolutional Coding is used for 4 Tx antennas, data tones at subcarrier indices = {245, 254, 515, 524, 785, 794} shall be punctured for additional pilots. If Convolutional Turbo Coding is used for 4 Tx antennas, the last 6 of 48 data tones shall be first truncated and the remaining 42 data tones shall be mapped at the following indices:

8.4.8.3.1.2.3 Burst packing of spatial multiplexed streams with CTC HARQ

For multiple spatial rate transmission and HARQ CTC, the packet shall be formed by concatenating multiple N_{EP}/N_{SCH} FEC codewords together. For the case of vertical encoding (number of layers = 1), there shall be only 1 CRC check at the end of the last codeword. The first block is of size N_{EP} and the second block of size N_{EP}-16 bits. For the case of horizontal encoding (number of layers > 1), each burst shall be a separate N_{EP}/N_{SCH} pair with separate CRC. The randomization seed shall be reset for all of the N_{EP}/N_{SCH} pairs in the combined codeword. Figure 277 shows an example of vertically encoded rate 2 with CTC HARQ transmission.

8.4.8.3.2 Symbol structure for the optional PUSC-ASCA

Symbol structure is defined in 8.4.6.3.1, pilots division between antennas per cluster for the STC/MIMO operation shall follow the division in the PUSC mode as defined in 8.4.8.1 and 8.4.8.2. Pilots may optionally be beamformed or precoded.

8.4.8.3.3 Transmission schemes for 2-antenna BS in DL

The following matrices define the transmission format with the row index indicating antenna number and column index indicating OFDMA symbol time. For both DL permutation zones with 2-antenna BS, one of the following three transmission matrices shall be used:

\[
A = \begin{bmatrix} S_i & -S_{i+1} \\ S_{i+1} & S_i \end{bmatrix}
\]

\[
B = \begin{bmatrix} S_i \\ S_{i+1} \end{bmatrix}
\]

\[
C = \frac{1}{\sqrt{1+r^2}} \begin{bmatrix} S_i \cdot j \cdot r \cdot S_{i+3} \\ S_{i+1} \cdot r \cdot S_i + S_{i+2} \end{bmatrix}
\]

where \( S_i \) and \( S_{i+1} \) in \( B \) may be encoded in different rates.

8.4.8.3.4 Transmission schemes for 3-antenna BS in DL

The definitions in this subclause are applicable to modes that support STC for 3-antenna Tx.
For 3-antenna BS, one of the three transmission matrices, \( A, B, \) or C, shall be used.

Let the complex symbols to be transmitted be \( x_1, x_2, x_3, x_4, \) which take values from a square QAM constellation; let \( s_i = x_i e^{j\theta} \) for \( i = 1, 2, \ldots, 8, \)

where \( \theta = \tan^{-1} \left( \frac{1}{3} \right) \); and let

\[
\tilde{s}_1 = s_{11} + j s_{34}, \quad \tilde{s}_2 = s_{21} + j s_{42}, \quad \tilde{s}_3 = s_{31} + j s_{12}, \quad s_4 = s_{44}.
\]

where \( s_i = x_i + j x_i' \).

The proposed Space-Time-Frequency code (over two OFDMA symbols and two subcarriers where the first two columns refer to the first subcarrier over two OFDMA symbols and last two columns refer to the second subcarrier over two OFMDA symbols) for 3Tx-Rate 1 configuration with diversity order 3 is given in three permuted versions as shown in Equation (84).

\[
A_1 = \begin{bmatrix}
\tilde{s}_1 - \tilde{s}_2 & 0 & 0 \\
\tilde{s}_2 & \tilde{s}_1 & \tilde{s}_3 - \tilde{s}_4 \\
0 & 0 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]

\[
A_2 = \begin{bmatrix}
\tilde{s}_1 - \tilde{s}_2 & 0 & 0 \\
\tilde{s}_2 & \tilde{s}_1 & 0 \\
0 & 0 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]

\[
A_3 = \begin{bmatrix}
\tilde{s}_1 - \tilde{s}_2 & 0 & 0 \\
0 & 0 & \tilde{s}_4 & \tilde{s}_3 \\
\tilde{s}_2 & \tilde{s}_1 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]

where the ML decoding can be achieved by symbol-by-symbol decoding.

The Matrix B is shown in Equation (85).

\[
B_1 = \begin{bmatrix}
\sqrt{\frac{2}{3}} & 0 & 0 & 0 \\
0 & \sqrt{\frac{2}{3}} & 0 & 0 \\
0 & 0 & \sqrt{\frac{2}{3}} & 0 \\
0 & 0 & 0 & \sqrt{\frac{2}{3}}
\end{bmatrix}
\]

\[
B_2 = \begin{bmatrix}
0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 0
\end{bmatrix}
\]

\[
B_3 = \begin{bmatrix}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{bmatrix}
\]

where the definitions for the remaining variables are as shown in Equation (86).
The Matrix C is used for spatial multiplexing and is shown in Equation (87).

\[
C = \begin{bmatrix}
S_1 \\
S_2 \\
S_3
\end{bmatrix}
\]  

The index, \( k \), of the permuted version of Matrix A and Matrix B to use for a particular deployment is given by:

\[
k = \text{mod} \left( \text{floor} \left( \frac{\text{logical_data_subcarrier_number_for_first_tone_of_code} - 1}{2} \right) , 3 \right) + 1,
\]

where \( \text{logical_data_subcarrier_number_for_first_tone_of_code} = 1, 2, 3, \ldots, \text{Total # of data subcarriers} \).

8.4.8.3.4.1 Enhanced 3-Tx Matrix A with Antenna Grouping

For 3-Tx antenna BS, transmission Matrix A in 8.4.8.3.4 may be employed with adaptive antenna grouping, which is fed back from MS.

When MS reports 0b000, 0b0111 or 0b101110 on its CQICH (see 8.4.11.3 and 8.4.11.7), then BS shall group antenna 0 and 1 for the first subcarrier and antenna 1 and 2 for the second subcarrier. In matrix form, it shall be read as shown in Equation (88).

\[
A_1 = \begin{bmatrix}
\tilde{s}_1 & \tilde{s}_2 & 0 & 0 \\
\tilde{s}_2 & \tilde{s}_1 & \tilde{s}_3 & -\tilde{s}_4 \\
0 & 0 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]  

When MS reports 0b001, 0b1000 or 0b101111 on its CQICH, then BS shall group antenna 0 and 1 for the first subcarrier and antenna 0 and 2 for the second subcarrier. In matrix form, it shall be read as shown in Equation (89).

\[
A_2 = \begin{bmatrix}
\tilde{s}_1 & \tilde{s}_2 & \tilde{s}_3 & -\tilde{s}_4 \\
\tilde{s}_2 & \tilde{s}_1 & 0 & 0 \\
0 & 0 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]  

When MS reports 0b010, 0b1001 or 0b110000 on its CQICH, then BS shall group antenna 0 and 1 for the first subcarrier and antenna 1 and 2 for the second subcarrier. In matrix form, it shall be read as shown in Equation (90).

\[
A_3 = \begin{bmatrix}
\tilde{s}_1 & \tilde{s}_2 & 0 & 0 \\
0 & 0 & \tilde{s}_3 & -\tilde{s}_4 \\
\tilde{s}_2 & \tilde{s}_1 & \tilde{s}_4 & \tilde{s}_3
\end{bmatrix}
\]

8.4.8.3.4.2 Enhanced 3-Tx Matrix B with antenna grouping

For 3-Tx antenna BS, transmission Matrix B for rate 2 may be employed with antenna grouping information that is fed back on a CQICH from MS.
When MS reports 0b000, 0b1010, or 0b110001 on its allocated CQICH, then BS shall transmit in the transmission matrix shown in Equation (91).

\[
B_1 = \begin{bmatrix}
- & - & - & - & - & - & - \\
- & s_7 & s_8 & s_3 & - & - & - \\
- & - & - & - & - & - & - \\
- & - & s_2 & s_4 & - & - & - \\
- & - & - & - & - & - & - \\
- & s_2 & s_1 & s_6 & - & - & - \\
- & - & - & - & - & - & -
\end{bmatrix}
\]  

(91)

When MS reports 0b001, 0b1011, or 0b110010 on its allocated CQICH, then BS shall transmit in the transmission matrix shown in Equation (92).

\[
B_2 = \begin{bmatrix}
- & - & - & - & - & - & - \\
- & s_1 & - & s_2 & s_4 & - & - \\
- & - & - & - & - & - & - \\
- & - & s_7 & s_8 & s_3 & - & - \\
- & - & - & - & - & - & - \\
- & s_2 & s_1 & s_6 & s_5 & - & - \\
- & - & - & - & - & - & -
\end{bmatrix}
\]  

(92)

When MS reports 0b010, 0b1100, or 0b110011 on its allocated CQICH, then BS shall transmit in the transmission matrix shown in Equation (93).

\[
B_3 = \begin{bmatrix}
- & - & - & - & - & - & - \\
- & s_1 & - & s_2 & s_4 & - & - \\
- & - & - & - & - & - & - \\
- & - & s_2 & s_1 & s_6 & s_5 & - & - \\
- & - & - & - & - & - & - \\
- & s_7 & s_8 & s_3 & - & - & - \\
- & - & - & - & - & - & -
\end{bmatrix}
\]  

(93)

8.4.8.3.4.3 3-Tx Matrix C with antenna selection

For the transmission Matrix C, when k substreams are configured, \(x_i = [s_1, s_2, \ldots, s_k]\), \(k = 1, \ldots, M\), \(M = 1, 2\). Transmission matrix is adaptively changed according to the CQICH. For 3-Tx antennas BS, the transmission matrix is listed in Table 474, where the mapping of the Matrix \(C_n\) to the CQICH is shown. The active antenna is power boosted.

<table>
<thead>
<tr>
<th>Streams, k</th>
<th>CQICH (binary)</th>

<td>0b110001</td>
<td>0b110010</td>
</tr>
<tr>
<td>(option 1)</td>
<td>(option 2)</td>
<td>(option 3)</td>
</tr>
</tbody>
</table>

Table 474—Enhanced 3-Tx Matrix C with antenna grouping
Stream $k = 2$ indicates TLV = 176, with Bit 1 and Bit 16 set.

### 8.4.8.3.5 Transmission schemes for 4-antenna BS

For all permutation zones using 4-antenna BS, one of the three transmission matrices in Equation (94), Equation (95), or Equation (96) shall be used:

\[
A = \begin{bmatrix}
  s_1 & -s_2^* & 0 & 0 \\
  s_2 & s_1^* & 0 & 0 \\
  0 & 0 & s_3 & -s_4^* \\
  0 & 0 & s_4^* & s_3 \\
\end{bmatrix}
\]

(94)

\[
B = \begin{bmatrix}
  s_1 & -s_2^* & s_3^* & -s_4^* \\
  s_2 & s_1^* & s_6 & -s_8 \\
  s_3 & -s_4 & s_7 & s_5^* \\
  s_4 & s_3 & s_8 & s_6 \\
\end{bmatrix}
\]

(95)

\[
C = \begin{bmatrix}
  s_1 \\
  s_2 \\
  s_3 \\
  s_4 \\
\end{bmatrix}
\]

(96)

where $s_i$ may have different rates.

The permuted matrix $A$ (over two OFDMA symbols and two subcarriers where the first two columns refer to the first subcarrier over two OFDMA symbols and the last two columns refer to the second subcarrier over two OFDMA symbols) for 4Tx-Rate 1 is given in three permuted matrices as shown in Equation (97).
The mapping of subscript \( k \) to determine the Matrix \( A_k \) is given by the following formula:

\[
k = \text{mod} \left( \text{floor} \left( \frac{\text{logical_data_subcarrier_number_for_first_tone_of_code} - 1}{2} \right) , 3 \right) + 1
\]

where

\[
\text{logical_data_subcarrier_number_for_first_tone_of_code} = 1, 2, 3, \ldots, \text{Total \# of data subcarriers}.
\]

The permuted matrix-\( B \) (over two OFDMA symbols and two subcarriers where the first two columns refer to the first subcarrier over two OFDMA symbols and the last two columns refer to the second subcarrier over two OFDMA symbols) for 4-Tx-Rate 2 is given in six permuted matrices as shown in Equation (98).

\[
\begin{align*}
A_1 &= \begin{bmatrix} S_1 & S_3^* & 0 & 0 \\ S_2 & S_1^* & 0 & 0 \\ 0 & 0 & S_3 & S_4^* \\ 0 & 0 & S_4 & S_3^* \end{bmatrix}, & A_2 &= \begin{bmatrix} S_1 & S_3^* & 0 & 0 \\ 0 & 0 & S_1 & S_4^* \\ S_2 & S_1^* & 0 & 0 \\ 0 & 0 & S_4 & S_3^* \end{bmatrix}, & A_3 &= \begin{bmatrix} S_1 & S_3^* & 0 & 0 \\ 0 & 0 & S_1 & S_4^* \\ S_2 & S_1^* & 0 & 0 \\ S_4 & S_3^* & 0 & 0 \end{bmatrix}
\end{align*}
\]

(97)

The mapping of subscript \( k \) to determine the Matrix \( B_k \) is given by the following formula:

\[
k = \text{mod} \left( \text{floor} \left( \frac{\text{logical_data_subcarrier_number_for_first_tone_of_code} - 1}{2} \right) , 6 \right) + 1
\]

where

\[
\text{logical_data_subcarrier_number_for_first_tone_of_code} = 1, 2, 3, \ldots, \text{Total \# of data subcarriers}.
\]

**8.4.8.3.5.1 Enhanced 4-Tx Matrix A with antenna grouping**

For 4-Tx antenna BS, transmission Matrix A in 8.4.8.3.5 may be employed with adaptive antenna grouping, which is fed back from MS.

When MS reports 0b101110 on its CQICH, then BS shall group antenna 0 and 1 for the first subcarrier and antenna 2 and 3 for the second subcarrier. In matrix form, it shall be read as shown in Equation (99).
When MS reports 0b101111 on its CQICH, then BS shall group antenna 0 and 2 for the first subcarrier and antenna 1 and 3 for the second subcarrier. In matrix form, it shall be read as shown in Equation (100).

$$A_1 = \begin{bmatrix} s_1 - s_2^* & 0 & 0 \\ s_2^* & 0 & 0 \\ 0 & 0 & s_3 - s_4^* \\ 0 & 0 & s_4 \ s_3^* \end{bmatrix}$$

When MS reports 0b110000 on its CQICH, then BS shall group antenna 0 and 3 for the first subcarrier and antenna 1 and 2 for the second subcarrier. In matrix form, it shall be read as shown in Equation (101).

$$A_2 = \begin{bmatrix} s_1 - s_2^* & 0 & 0 \\ 0 & 0 & s_3 - s_4^* \\ s_2^* & 0 & 0 \\ 0 & 0 & s_4 \ s_3^* \end{bmatrix}$$

When MS reports 0b110001 on its allocated CQICH, then BS shall group antenna 0 and 1 for the first diversity pair and antenna 2 and 3 for the second diversity pair. In matrix form, it shall be read as shown in Equation (102).

$$B_1 = \begin{bmatrix} s_1 - s_2^* & s_3 - s_7^* \\ s_2^* & s_5 \ s_9^* \\ s_3 - s_4^* & s_6 - s_8^* \\ s_4 \ s_5^* & s_6 \ s_8^* \end{bmatrix}$$

When MS reports 0b110010 on its allocated CQICH, then BS shall transmit in the transmission matrix as shown in Equation (103).
When MS reports 0b1110011 on its allocated CQICH, then BS shall group antenna 0 and 2 for the first diversity pair and antenna 1 and 3 for the second diversity pair. In matrix form, it shall be read as shown in Equation (103).

\[
B_5 = \begin{bmatrix}
- s_1 & s_2 & - s_4 & s_6 & - s_7 \\
- s_2 & s_1 & - s_5 & s_7 & s_4 \\
- s_4 & s_3 & s_8 & - s_6 & s_5 \\
- s_3 & - s_4 & - s_6 & - s_8 \\
\end{bmatrix}
\] (103)

When MS reports 0b1110100 on its allocated CQICH, then BS shall transmit in the transmission matrix as shown in Equation (104).

\[
B_6 = \begin{bmatrix}
- s_1 & s_2 & - s_4 & s_6 & - s_7 \\
- s_2 & s_1 & - s_5 & s_7 & s_4 \\
- s_4 & s_3 & s_8 & - s_6 & s_5 \\
- s_3 & - s_4 & - s_6 & - s_8 \\
\end{bmatrix}
\] (104)

When MS reports 0b1110101 on its allocated CQICH, then BS shall group antenna 0 and 3 for the first diversity pair and antenna 1 and 2 for the second diversity pair. In matrix form, it shall be read as shown in Equation (105).

\[
B_7 = \begin{bmatrix}
- s_1 & s_2 & - s_4 & s_6 & - s_7 \\
- s_2 & s_1 & - s_5 & s_7 & s_4 \\
- s_4 & s_3 & s_8 & - s_6 & s_5 \\
- s_3 & - s_4 & - s_6 & - s_8 \\
\end{bmatrix}
\] (105)

When MS reports 0b1110110 on its allocated CQICH, then BS shall transmit in the transmission matrix as shown in Equation (106).

\[
B_8 = \begin{bmatrix}
- s_1 & s_2 & - s_4 & s_6 & - s_7 \\
- s_2 & s_1 & - s_5 & s_7 & s_4 \\
- s_4 & s_3 & s_8 & - s_6 & s_5 \\
- s_3 & - s_4 & - s_6 & - s_8 \\
\end{bmatrix}
\] (106)

When MS reports 0b1110111 on its allocated CQICH, then BS shall transmit in the transmission matrix as shown in Equation (107).

\[
B_9 = \begin{bmatrix}
- s_1 & s_2 & - s_4 & s_6 & - s_7 \\
- s_2 & s_1 & - s_5 & s_7 & s_4 \\
- s_4 & s_3 & s_8 & - s_6 & s_5 \\
- s_3 & - s_4 & - s_6 & - s_8 \\
\end{bmatrix}
\] (107)
8.4.8.3.5.3 4-Tx Matrix C with antenna selection

For 4-Tx antennas BS, the transmission matrix is listed in Table 475, where the mapping of the Matrix $C_n$ to the CQICH is shown. The active antenna is power boosted.

Table 475—Mapping of precoding matrix and CQICH for 4-Tx Matrix C with antenna selection

Stream $k = 2$ indicates TLV = 176, with Bit 1 and Bit 16 set.
Stream $k = 3$ indicates TLV = 176, with Bit 11 and Bit 16 set.

8.4.8.3.6 MIMO precoding

The space time coding output can be weighted by a matrix before mapping onto Tx antennas:

$$z = Wx$$

where $x$ is a $M \times 1$ vector with the output from the space-time coding (per-subcarrier), $M$ is the number of streams at the output of the space-time coding scheme. The matrix $W$ is an $N_t \times M$ weighting matrix where the quantity $N_t$ is the number of actual Tx antennas. The vector $z$ contains the signals after weighting for the different actual antennas. The labeling of the elements in the weighting matrix $W$ is performed in accordance with the example of $W$ given in Equation (108) for the case of four actual antennas and two space-time coding output streams. the number of actual Tx antennas ($N_t$) is equal to the number of antennas used for the
If the midamble is not present, $N_t$ is equal to the number of antennas specified by the STC zone IE.

$$
W = \begin{bmatrix}
W_{11} & W_{12} \\
W_{21} & W_{22} \\
W_{31} & W_{32} \\
W_{41} & W_{42}
\end{bmatrix}
$$

(108)

a) **Short-term closed-loop precoding.** When $M_t = 1$, then single stream precoding or beamforming shall be applied with the vector $W$ of dimension $N_t \times 1$. The transmission scheme before the precoder is the regular single antenna transmission. When $M_t = 2, 3$ or 4, then the two, three, or four STC output streams shall be transmitted with a precoding matrix of dimension $N_t \times 2, N_t \times 3, N_t \times 4$.

When using CQICH feedback type 0b100 (Index to precoding matrix in codebook) in Table 396, the number of bits in the precoding matrix index in the codebook is determined by the number of bits in the CQICH Type (also in Table 396).

b) **Long-term closed-loop precoding.** The rank of the precoding matrix is indicated in the long-term precoding feedback from the SS. The number of columns in the precoding matrix equals its rank. The STC scheme used, Matrix A, B or C, is selected from the set of STC schemes associated with the number of Tx antennas equaling the rank of the long-term precoding matrix used. For example, if the rank of the long-term precoding matrix is 2 and the spatial rate used is 1 then the Matrix A scheme for 2 Tx antennas is used.

When the long-term closed-loop precoding is turned on, the life span of short-term precoding information, the rank of the long-term precoding codebook used and the index to the precoding matrix in the specified long-term precoding codebook is fed back with MAC header feedback messages 0b0000 and 0b0001. If a short-term precoding matrix is available, the BS shall use this short-term matrix. If not, the BS shall use the fed back long-term precoding matrix, if available.

The long-term closed-loop precoding uses the 6-bit codebook as specified in 8.4.11.12.

c) **Feeding back multiple precoder for band AMC operation.** For band AMC the BS may request a common precoding matrix for all bands or request a programmable number, $N$ (see Table 17 and Table 396), precoding matrices to be fed back for the $N$ best bands. In the latter case, the precoding matrices are fed back from the lowest AMC band index to the highest index. If a common precoder for all AMC bands is requested it is signaled in the CQICH channels. For the case where the dedicated pilot bit is set to 1 in the STC Zone IE (8.4.5.3.4) for the zone in which the subburst allocations are made, if the BS requests a common precoding matrix for all bands, a single precoding matrix shall be fed back based on the allocated bands. If the BS requests a programmable number $N$ (see Table 17 and Table 396) of precoding matrices to be fed back for the $N$ bands, they are signaled in the order described previously, over the corresponding CQICH channels or feedback header type 1101.

d) **Precoding state feed forward and precoding application delay.** If the precoding state is not fed forward in the DL burst allocation IE, then the BS shall apply precoding according to the precoding feedback from the SS (antenna grouping, antenna selection or codebook based) with a predetermined number of frames delay.

### 8.4.8.4 STC for the optional zones in the UL

Two optional zones in the UL, the optional PUSC and the optional AMC zones, are described in 8.4.6.2.5 and 8.4.6.3, respectively. STC may be used to improve system performance for these zones. Furthermore, two single Tx antenna MSs can perform collaborative spatial multiplexing onto the same subcarrier.
8.4.8.4.1 Allocation of pilot subcarriers

For 2-antenna MS and the optional PUSC, pilots for each antenna shall be allocated as shown in Figure 279.

<table>

Figure 280—Uplink pilot allocation for 2 dual antenna MSs performing collaborative spatial multiplexing

8.4.8.4.2 Allocation of data subchannels

For the optional PUSC permutation with Matrix A in 8.4.8.4.3, the data subchannels shall be allocated for two consecutive slots in time. As can be seen in Figure 281, STC encoded data symbols shall be time mapped over two OFDMA symbols. The mapping starts at the lowest numbered subcarriers of lowest slot and continues in an ascending manner in subchannels first and then proceeds to the next two symbols in time.

When collaborative spatial multiplexing is performed by two MSs with dual Tx antennas, the data mapping rule shall be identical to the data mapping rule in Matrix A.
For 2-antenna Matrix B in the optional PUSC permutation, modulated data symbols shall be sequentially mapped for two Tx antennas along the subcarriers in the symbol. The mapping continues in an ascending manner in subchannels first and then proceeds to the next symbol in time.

For the UL optional AMC permutation with Matrix A and B, the subcarrier permutation represented by Equation (75) 8.4.6.3 shall not be applied for the UL optional AMC permutation with Matrix A and B. The data mapping rule is identical to that for the DL AMC permutation with two antennas. For the UL optional AMC permutation with collaborative spatial multiplexing, the data mapping rule shall be identical to the mapping in single antenna transmission and the minimum allocation shall be six symbols.

### 8.4.8.4.3 Transmission schemes for 2-antenna MS in UL

The following matrices define the transmission format with the row index indicating antenna number and column index indicating OFDMA symbol time. For both UL permutation zones with 2-antenna MS, one of the following two transmission matrices shall be used:

\[
A = \begin{bmatrix}
  S_i & -S^*_i+1 \\
  S^*_i+1 & S_i
\end{bmatrix}
\]

\[
B = \begin{bmatrix}
  S_i \\
  S^*_i+1
\end{bmatrix}
\]

where \(S_i\) and \(S^*_i+1\) may be encoded in different rates.

The Matrix B may also be used for two single antenna MSs to share the same subchannel (collaborative spatial multiplexing).

### 8.4.8.5 MIMO midamble

The MIMO midamble consists of one OFDM symbol that is mapped onto multiple antennas. nonoverlapping subcarriers are allotted to the Tx antennas.
The index of the subcarrier starts from the first one after the left guard band. DC subcarrier is also included in the numbering but nulled prior to transmission. The midamble carrier-set is defined using the following formula:

\[
\text{Midamble\_Carrier\_Set} = -(N_{used} - 1)/2 + n + 2k \left\lceil \frac{N_t}{2} \right\rceil
\]

where

- \( N_t \) is the number of Tx antennas (2, 3, or 4)
- \( n \) is the antenna index (0, 1, \ldots, \( N_t - 1 \); \( N_t \leq 4 \))
- \( k \) is the subcarrier running index

For FUSC, optional FUSC, PUSC and adjacent subcarrier permutation, the antenna to subcarrier mapping is shown in Figure 282 for the case when \( N_t = 4 \). The midamble sequence has a mapping to midamble IDcell which is identical to the preamble index.

![Figure 282—Midamble structure (frequency domain)](image)

### 8.4.8.5.1 Midamble sequence

The subcarrier locations and corresponding PN code BPSK modulation of subcarriers in a midamble are defined as in Equation (109) and Equation (110). The DC subcarrier is also included in the numbering but nulled prior to transmission.

\[
P_{ID,\text{cell}}[k_{foi}] = \begin{cases} 
1 - (2)q_{ID,\text{cell}}[m], & k_{foi} = 2m \left\lceil \frac{N_t}{2} \right\rceil - \frac{N_{used} - 1}{2} + n, \text{ and } m = 0, 1, \ldots, m_{MAX}, \text{ and } k_{foi} < \frac{N_{used} - 1}{2} \\
0, & \text{otherwise}
\end{cases} 
\tag{109}
\]

\[
q_{ID,\text{cell}}[m] = \begin{cases} 
R \left( \frac{m}{9} \right) + m \mod 9, & m \mod 9 = 0, 1, 2, \ldots, 7 \\
T \left( \frac{m}{9} \right), & m \mod 9 = 8
\end{cases} \quad \text{where } m = 0, 1, \ldots, m_{MAX} 
\tag{110}
\]

where

- \( N_t \) is the number of Tx antennas (2, 3, or 4)
- \( n \) is the antenna index (0, 1, \ldots, \( N_t - 1 \); \( N_t \leq 4 \))
$k$ is the subcarrier running index

$$m_{\text{MAX}} = \left\lceil \frac{N_{\text{used}} - 1}{2} \right\rceil$$

The sequence $R(r)$ in Equation (110) is either one of the formulas in Equation (111) or Equation (112), depending on $N_{\text{FFT}}$ and $N_T$. The choice of the sequence $R(r)$ and the length of sequence $N_r$ supporting the choice are shown in Table 478.

$$R_1(r) = H_{128}(ID_{\text{cell}}+1, \Pi_{\lfloor r \mod 128 \rfloor} r, m) \mod 9 = 0, 1, \ldots, N_r-1$$

(111)

$$R_2(r) = B_{ID_{\text{cell}}} + g_{B(r)} r, m) \mod 9 = 0, 1, \ldots, N_r-1$$

(112)

<table>
<thead>
<tr>
<th>$N_T$</th>
<th>2</th>
<th>3 or 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>$N_{\text{FFT}}$</td>
<td>2048</td>
<td>1024</td>
</tr>
<tr>
<td>$R_1(r)$</td>
<td>768</td>
<td>384</td>
</tr>
<tr>
<td>$R_2(r)$</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

In $R_1(r)$, $H_{128}(i, j)$ denotes the number at $(i, j)$ of order 128 Walsh Hadamard matrix, where $i, j = 0, 1, \ldots, 127$. The first low vector of $H_{128}$ is the all-one sequence and shall not be used. $\Pi_{\lfloor m \mod 9 \rfloor} l, m) \mod 9 = 0, 1, \ldots, 127$ is the $l$-th value of the $\lfloor m \mod 9 \rfloor$th permutation out of six predefined permutations shown in Table 479.

In $R_2(r)$, if the $k$, $1 \leq k \leq 127$ can be converted into binary as $b_6 b_5 b_4 b_3 b_2 b_1 b_0$, define $b_6$ as the MSB, $b_0$ as the LSB, $B_k$ is a $(1 \times 7)$ row vector to represent $B_k = [b_0 b_1 b_2 b_3 b_4 b_5 b_6]$. The $g_u 0 \leq u \leq N_r-1$ is $u$th column vector of the generator matrix $G$. $B_k g_u$ is a product of $(1 \times 7)$ row vector and $(7 \times 1)$ column vector. The generator matrix $G$ and the permutation $\Pi_{\lfloor m \mod 9 \rfloor} l, m) \mod 9 = 0, 1, 2, \ldots, N_r-1$ for each $N_{\text{FFT}}$ and $N_T$ are shown in 8.4.8.5.1.1 and 8.4.8.5.1.2.

The sequence $T(k)$ is determined by IDcell and should be chosen to achieve low PAPR.

### 8.4.8.5.1.1 PAPR reduction sequence for BS with two antennas

The PAPR reduction sequences for BS with two antennas are listed in Table 480, Table 481, Table 482, and Table 484 for the cases of 2048-FFT, 1024-FFT, and 512-FFT, and 128-FFT, respectively. Table 483 specifies the permutations.

Table 485 specifies the permutations for BS with three and four antennas and FFT size = 512. The PAPR
reduction sequences for BS with 3 and 4 antennas and FFT size = 512 are listed in Table 486.
Table 485—Permutation (l = 0, 1, 2, …, 95)

8.4.8.6 STC subpacket combining

In the STC transmission, for both DL and UL, the STC subpacket retransmission can be generated by using the Space time code incremental redundancy version. The transmission rule for space-time coded incremental redundancy codes set is listed in Table 489, Table 490, and Table 491.

### Table 489—STC subpacket combining (2-Tx antenna case)

S_2^{(odd)} = \begin{bmatrix} -S_2^* \\ S_1^* \\ S_3^* \\ S_4^* \end{bmatrix}
\]

\[
S_2^{(even)} = \begin{bmatrix} S_1 \\ S_2 \\ S_3 \\ S_4 \end{bmatrix}
\]
The MS shall process the initial transmission, first retransmission, and second retransmission, etc., in the form of space time decoding. The retransmission of FEC codeword shall use the Chase combing retransmission.

### 8.4.8.7 Cyclic delay diversity (CDD)

The BS and MS may apply the cyclic delay diversity (CDD) technique in order to improve performance or split the power between multiple transmit antennas. The same signal (including data, pilots, preamble, midamble, etc) may be transmitted from several antennas simultaneously, with different cyclic delay applied to each signal in order to reduce the potential of nulling in the receiver’s antenna. Cyclic delay means the samples in the useful symbol time $T_b$ are shifted $D$ samples forward, the last $D$ samples are copied to the first $D$ samples, and the CP is regenerated from the last samples of the rotated symbol. An equivalent description is to multiply all subcarriers by $w_k = \exp\left(-\frac{j2\pi Dk}{N}\right)$. Each transmit antenna uses a different delay value and potentially a different gain and phase.

In case of applying such techniques then in all references to “antenna 0,” “antenna 1,” and so forth, in the rest of 8.4, shall refer to a logical antenna, representing the signal defined in 8.4.2.5, which may be transmitted from several physical antennas. An example is shown in Figure 283.

![Figure 283—Example of single logical antenna split into two physical antennas with cyclic delays](image)

For example, a 2 antenna BS using a 2 antenna STC zone, may use CDD in the first zone (with a single logical antenna) in order to effectively split the transmitted power between the two antennas and obtain diversity gain.

The following requirements apply to CDD:

1) The CDD parameters and arrangement of antennas shall not change within the zone. For this purpose the preamble is considered a part of the first PUSC zone.

2) The CDD parameters (delays and powers) and arrangement of antennas shall be the same over zones which have broadcast pilots (dedicated pilots = 0) and have the same number of antennas specified in the STC zone IE, over all frames. For this purpose the first PUSC zone is considered to have dedicated pilots = 0 and number of antennas equals 1.

3) All references to the power transmitted from an antenna (antenna $#k$) shall be interpreted as the total power transmitted from physical antennas associated with logical antenna $#k$.
4) Zone boosting limitations of 8.4.9.6 shall be kept with respect to the total power as defined above.

5) The maximum delay in any physical antenna relative to the reference antenna (antenna #0) shall not exceed 1.4% of the useful symbol time $T_b$ in any zone. The delay shall always be positive.

6) If the power used by physical antennas associated with the same logical antenna is not equal, it is recommended that antennas transmitting higher power shall use smaller delay values.

### 8.4.9 Channel coding

Channel coding procedures including randomization (see 8.4.9.1), FEC encoding (see 8.4.9.2), bit interleaving (see 8.4.9.3), repetition (see 8.4.9.5), and modulation (see 8.4.9.4) are shown in Figure 284.

![Figure 284—Channel coding process for regular and repetition coding transmission](image)

Repetition shall be applied only to QPSK modulation.

#### 8.4.9.1 Randomization

Data randomization is performed on all data transmitted on the DL and UL, except the FCH. The randomization is initialized on each FEC block. If the amount of data to transmit does not fit exactly the amount of data allocated, padding of 0xFF (1 only) shall be added to the end of the transmission block up to the amount of data allocated. Here, the amount of data allocated means the amount of data that corresponds to the amount of $\left\lfloor \frac{N_s}{R} \right\rfloor$ slots, where $N_s$ is the number of the slots allocated for the data burst and $R$ is the repetition factor used.

The PRBS generator shall be $1 + x^{14} + x^{15}$, as shown in Figure 285. Each data byte to be transmitted shall enter sequentially into the randomizer, MSB first. Preambles are not randomized. The seed value shall be
used to calculate the randomization bits, which are combined in an XOR operation with the serialized bit stream of each FEC block. The randomizer sequence is applied only to information bits.

The bit issued from the randomizer shall be applied to the encoder.

The randomizer is initialized with the vector \([\text{LSB}] 0 1 1 0 1 1 0 0 0 1 0 1 0 1 [\text{MSB}]\).

HARQ requires that the randomizer pattern be identical for each HARQ attempt. For HARQ operation, the randomizer shall be initialized with the vector created as shown in Figure 286.

8.4.9.2 Encoding

The coding method used as the mandatory scheme shall be the tail-biting convolutional encoding specified in 8.4.9.2.1, and the optional modes of encoding in 8.4.9.2.2 and 8.4.9.2.3 shall be also supported.

The encoding block size shall depend on the number of slots allocated and the modulation specified for the current transmission.

Concatenation of a number of slots shall be performed in order to make larger blocks of coding where it is possible, with the limitation of not exceeding the largest supported block size for the applied modulation and coding. Table 493 specifies the concatenation of slots for different allocations and modulations. The parameters in Table 492 and Table 493 shall apply to the CC encoding scheme (see 8.4.9.2.1) and the BTC encoding scheme (see 8.4.9.2.2). For the CTC encoding scheme (see 8.4.9.2.3), the concatenation rule is defined in 8.4.9.2.3.3, and for the LDPC encoding scheme (see 8.4.9.2.5) the concatenation rule is defined in 8.4.9.2.5.3.

Figure 285—PRBS generator for data randomization

Figure 286—Creation of OFDMA randomizer initialization vector for HARQ
For any modulation and FEC rate, given an allocation of \( n \) slots, the following parameters are defined:

- \( j \) is parameter dependent on the modulation and FEC rate
- \( n \) is floor (number of allocated slots * STC rate/(repetition factor * number of STC layers))
- \( k \) is floor \( n/j \)
- \( m \) is \( n \) modulo \( j \)

Table 492 shows the rules used for slot concatenation.

**8.4.9.2.1 Convolutional coding (CC)**

Each FEC block is encoded by the binary convolutional encoder, which shall have native rate of 1/2, a constraint length equal to \( K = 7 \), and shall use the following generator polynomials codes to derive its two code bits:

\[
G_1 = 171_{\text{oct}} \quad \text{FOR} \ X
\]
\[
G_2 = 133_{\text{oct}} \quad \text{FOR} \ Y
\]

(115)
The generator is depicted in Figure 287.

![Convolutional encoder of rate 1/2](image)

Figure 287—Convolutional encoder of rate 1/2

The puncturing patterns and serialization order that shall be used to realize different code rates are defined in Table 494. In the table, “1” means a transmitted bit and “0” denotes a removed bit, whereas $X$ and $Y$ are in reference to Figure 287.

<table>
<thead>
<tr>
<th>Code rates</th>
<th>Rate</th>
<th>1/2</th>
<th>2/3</th>
<th>3/4</th>
</tr>
</thead>
<tbody>
<tr>
<td>$d_{free}$</td>

<td>$XY$</td>
<td></td>
<td>$X_1Y_1$</td>
<td>$X_1Y_1Y_2$</td>
<td>$X_1Y_1Y_2X_3$</td>
</tr>
</tbody>
</table>

Each FEC block is encoded by a tail-biting convolutional encoder, which is achieved by initializing the encoder’s memory with the last data bits of the FEC block being encoded (the packet data bits numbered $b_{n-5}...b_n$).

Table 495 defines the basic sizes of the useful data payloads to be encoded in relation with the selected modulation type and encoding rate and concatenation rule.

### Table 494—Convolutional code with puncturing configuration

8.4.9.2.1.1 Incremental redundancy HARQ support (optional)

HARQ implementation is optional. An incremental redundancy (IR) based HARQ is taking the puncture pattern into account, and for each retransmission the coded block is not the same. Different puncture patterns are used to create HARQ packets identified by SPID. The puncture patterns are predefined or can be easily
deducted from the original pattern, and can be selected based on SPID. At the receiver, the received signals are depunctured according to its specific puncture pattern, which is decided by the current SPID, then the combination is performed at bit metrics level.

The puncture pattern for the HARQ packet with SPID = 0 is the same as the mandatory one in Table 496. The puncture pattern for the HARQ packet with SPID = 1 is the left cyclic shift of the one from SPID = 0, as shown in Table 496. Following the same rule, the puncture patterns for packets with SPID = 2 and SPID = 3 are shown in Table 496.

</tbody>
</table>
8.4.9.2.2 Block turbo coding (BTC) (optional)

The BTC is based on the product of two simple component codes, which are binary extended Hamming codes or parity check codes from the set depicted in Table 497.

Table 497 specifies the generator polynomials for the Hamming codes. To create extended Hamming codes, an overall even parity check bit is added at the end of each code word.

Table 497—OFDMA Hamming code generator polynomials

<table>
<thead>
<tr>
<th>n'</th>
<th>k'</th>
<th>Generator polynomial</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>11</td>
<td>(x^4 + x^4 + 1)</td>
</tr>
<tr>
<td>31</td>
<td>26</td>
<td>(x^5 + x^2 + 1)</td>
</tr>
<tr>
<td>63</td>
<td>57</td>
<td>(x^6 + x^1 + 1)</td>
</tr>
</tbody>
</table>

The component codes are used in a two-dimensional matrix form, which is depicted in Figure 288. The \(k_x\) information bits in the rows are encoded into \(n_x\) bits by using the component block \((n_x, k_x)\) code specified for the respective composite code. After encoding the rows, the columns are encoded using a block code \((n_y, k_y)\), where the check bits of the first code are also encoded. The overall block size of such a product code is \(n = n_x \times n_y\), the total number of information bits \(k = k_x \times k_y\), and the code rate is \(R = R_x \times R_y\), where \(R_i = k_i / n_i\), \(i = x, y\). The Hamming distance of the product code is \(d = d_x \times d_y\). Data bit ordering for the composite BTC matrix is the first bit in the first row is the LSB and the last data bit in the last data row is the MSB.

Transmission of the block over the channel shall occur in a linear fashion, with all bits of the first row transmitted left to right followed by the second row, etc.

To match a required packet size, BTCs may be shortened by removing symbols from the BTC array. In the two-dimensional case, rows, columns, or parts thereof can be removed until the appropriate size is reached.

There are three steps in the process of shortening product codes:

Step 1) Remove \(I_x\) rows and \(I_y\) columns from the two-dimensional code. This is equivalent to shortening the constituent codes that make up the product code.

Step 2) Remove \(B\) individual bits from the first row of the two-dimensional code starting with the LSB.

Step 3) Use if the product code specified from Step 1) and Step 2) of this subclause has a nonintegral number of data bytes. In this case, the \(Q\) leftover LSB are zero-filled by the encoder. After decoding at the receive end, the decoder shall strip off these unused bits and only the specified data payload is passed to the next higher level in the PHY. The same general method is used for shortening the last code word in a message where the available data bytes do not fill the available data bytes in a code block.

These three processes of code shortening are depicted in Figure 288. In the first two-dimensional BTC, a nonshortened product code is shown. By comparison, a shortened BTC is shown in the adjacent two-dimensional array. The new coded block length of the code is \((n_x - I_x)(n_y - I_y) - B\). The corresponding information length is given as \((k_x - I_x)(k_y - I_y) - B - Q\). Consequently, the code rate is given by Equation (116).

\[
R = \frac{(k_x - I_x)(k_y - I_y) - B - Q}{(n_x - I_x)(n_y - I_y) - B} \quad (116)
\]
Table 498 gives the block sizes for the optional modulation and coding schemes using BTC. Table 499 gives the code parameters for each of the possible data and coded block sizes.

8.4.9.2.3 Convolutional turbo codes (CTCs) (optional)

8.4.9.2.3.1 CTC encoder

The CTC encoder, including its constituent encoder, is depicted in Figure 289. The CTC defined in this subclause can be used for the support of the optional HARQ. It uses a double binary Circular Recursive Systematic Convolutional code. The bits of the data to be encoded are alternately fed to $A$ and $B$, starting with the MSB of the first byte being fed to $A$. The encoder is fed by blocks of $k$ bits or $N$ couples ($k = 2 \times N$ bits). For all the frame sizes, $k$ is a multiple of 8 and $N$ is a multiple of 4. Further, $N$ shall be limited to $8 \leq N/4 \leq 1024$.

The polynomials defining the connections are described in octal and symbol notations as follows:

![Figure 288—BTC and shortened BTC structure](image-url)
For the feedback branch: 0xB, equivalently $1 + D + D^3$ (in symbolic notation)
For the $Y$ parity bit: 0xD, equivalently $1 + D^2 + D^3$
For the W parity bit: 0x9, equivalently $1 + D^3$

![Diagram](image)

**Figure 289—CTC encoder**

First, the encoder (after initialization by the circulation state $S_{c1}$, see 8.4.9.2.3.3) is fed the sequence in the natural order (position 1) with the incremental address $i = 0 .. N-1$. This first encoding is called $C_1$ encoding. Then the encoder (after initialization by the circulation state $S_{c2}$, see 8.4.9.2.3.3) is fed by the
interleaved sequence (switch in position 2) with incremental address $j = 0, \ldots, N - 1$. This second encoding is called $C_2$ encoding.

The order in which the encoded bit shall be fed into the subpacket generation block (8.4.9.2.3.4) is

$$A, B, Y_1, Y_2, W_1, W_2 = \ldots$$

Note that the interleaver (8.4.9.3) shall not be used when using CTC.

The encoding block size shall depend on the number of slots allocated and the modulation specified for the current transmission. Concatenation of a number of slots shall be performed in order to make larger blocks of coding where it is possible, with the limitation of not exceeding the largest supported block size for the applied modulation and coding. Table 501 specifies the concatenation of slots for different allocations and modulations. The concatenation rule shall not be used when using IR HARQ.

For any modulation and FEC rate, given an allocation of $n$ slots, the following parameters are defined:

- $j$ is parameter dependent on the modulation and FEC rate
- $n$ is floor(number of allocated slots * STC rate/(repetition factor * number of STC layers))
- $k$ is floor($n/j$)
- $m$ is $n \mod j$

Table 500 shows the rules used for slot concatenation.

Table 502 gives the block sizes, code rates, channel efficiency, and code parameters for the different modulation and coding schemes. As 64-QAM is optional, the codes for this modulation shall only be implemented if the modulation is implemented. Table 503 shows code parameters for HARQ.

#### 8.4.9.2.3.2 CTC interleaver

The interleaver requires the parameters $P₀$, $P₁$, $P₂$, and $P₃$ shown in Table 502.

The two-step interleaver shall be performed as follows:

**Step 1: Switch alternate couples**

Let the sequence $u₀ = [(A₀, B₀), (A₁, B₁), (A₂, B₂), (A₃, B₃), \ldots, (A_{N−1}, B_{N−1})]$ be the input to first encoding $C₁$.

for $i = 0 \ldots N−1$

if ($i$ mod 2), let $(Aᵢ, Bᵢ) → (Bᵢ, Aᵢ)$ (i.e., switch the couple)

This step gives a sequence $u₁ = [(A₀, B₀), (B₁, A₁), (A₂, B₂), (B₃, A₃), \ldots, (B_{N−1}, A_{N−1})] = [u₁(0), u₁(1), u₁(2), u₁(3), \ldots, u₁(N−1)]$.

**Step 2: $P(j)$**

The function $P(j)$ provides the address of the couple of the sequence $u₁$ that shall be mapped onto the address $j$ of the interleaved sequence (i.e., $u₂(j) = u₁(P(j))$).

for $j = 0 \ldots N−1$

switch ($j$ mod 4):
case 0: \(P(j) = (P_0 \cdot j + 1) \mod N\)

case 1: \(P(j) = (P_0 \cdot j + 1 + N/2 + P_1) \mod N\)

case 2: \(P(j) = (P_0 \cdot j + 1 + P_2) \mod N\)

case 3: \(P(j) = (P_0 \cdot j + 1 + N/2 + P_3) \mod N\)

This step gives a sequence \(u_2 = [u_1(P(0)), u_1(P(1)), u_1(P(2)), u_1(P(3)), \ldots, u_1(P(N-1))]\) = \([B_{P(0)}, A_{P(0)}], (A_{P(1)}, B_{P(1)}), (B_{P(2)}, A_{P(2)}), (A_{P(3)}, B_{P(3)}), \ldots, (A_{P(N-1)}, B_{P(N-1)})]\). Sequence \(u_2\) is the input to the second encoding \(C_2\).

8.4.9.2.3.3 Determination of CTC circulation states

The state of the encoder is denoted \(S(0 \leq S \leq 7)\) with \(S = 4s_1 + 2s_2 + s_3\) (see Figure 289). The circulation states \(S_{c1}\) and \(S_{c2}\) are determined by the following operations:

a) Initialize the encoder with state 0. Encode the sequence in the natural order for the determination of \(S_{c1}\) or in the interleaved order for determination of \(S_{c2}\). In both cases the final state of the encoder is \(S_{0N-1}\);

b) According to the length \(N\) of the sequence, use Table 504 to find \(S_{c1}\) or \(S_{c2}\).

8.4.9.2.3.4 Subpacket generation

Proposed FEC structure punctures the mother codeword to generate a subpacket with various coding rates. The subpacket is also used as HARQ packet transmission. Figure 290 shows a block diagram of subpacket generation. 1/3 CTC encoded codeword goes through interleaving block and the puncturing is performed. Figure 291 shows block diagram of the interleaving block. The puncturing is performed to select the consecutive interleaved bit sequence that starts at any point of whole codeword. For the first transmission, the subpacket is generated to select the consecutive interleaved bit sequence that starts from the first bit of the systematic part of the mother codeword. The length of the subpacket is chosen according to the needed

Figure 290—Block diagram of subpacket generation

8.4.9.2.3.4.1 Bit separation

All of the encoded bits shall be demultiplexed into six subblocks denoted $A$, $B$, $Y_1$, $Y_2$, $W_1$, and $W_2$. The encoder output bits shall be sequentially distributed into six subblocks with the first $N$ encoder output bits going to the $A$ subblock, the second $N$ encoder output going to the $B$ subblock, the third $N$ to the $Y_1$ subblock, the fourth $N$ to the $Y_2$ subblock, the fifth $N$ to the $W_1$ subblock, and the sixth $N$ to the $W_2$ subblock.
8.4.9.2.3.4.2 Subblock interleaving

The six subblocks shall be interleaved separately. The interleaving is performed by the unit of bits. The sequence of interleaver output bits for each subblock shall be generated by the procedure described below. The entire subblock of bits to be interleaved is written into an array at addresses from 0 to the number of the bits minus one \((N-1)\), and the interleaved bits are read out in a permuted order with the \(i\)-th bit being read from an address, \(AD_i \ (i = 0... N-1)\), as follows:

a) Determine the subblock interleaver parameters, \(m\) and \(J\). Table 505 gives these parameters.

b) Initialize \(i\) and \(k\) to 0.

c) Form a tentative output address \(T_k\) according to the following formula:
   \[ T_k = 2^m(k \mod J) + \text{BRO}_m\left\lfloor k/J \right\rfloor \]
   where \(\text{BRO}_m(y)\) indicates the bit-reversed \(m\)-bit value of \(y\) (i.e., \(\text{BRO}_3(6) = 3\)).

d) If \(T_k\) is less than \(N\ AD_i = T_k\) and increment \(i\) and \(k\) by 1. Otherwise, discard \(T_k\) and increment \(k\) only.

e) Repeat steps 3) and 4) until all \(N\) interleaver output addresses are obtained.

The parameters for the subblock interleavers are specified in Table 505, and the parameters for the subblock interleavers when supporting HARQ are specified in Table 506.

8.4.9.2.3.4.3 Bit grouping

The channel interleaver output sequence shall consist of the interleaved \(A\) and \(B\) subblock sequence, followed by a bit-by-bit multiplexed sequence of the interleaved \(Y_1\) and \(Y_2\) subblock sequences, followed by a bit-by-bit multiplexed sequence of the interleaved \(W_1\) and \(W_2\) subblock sequences. The bit-by-bit multiplexed sequence of interleaved \(Y_1\) and \(Y_2\) subblock sequences shall consist of the first output bit from the \(Y_1\) subblock interleaver, the first output bit from the \(Y_2\) subblock interleaver, the second output bit from the \(Y_1\) subblock interleaver, the second output bit from the \(Y_2\) subblock interleaver, etc. The bit-by-bit multiplexed sequence of interleaved \(W_1\) and \(W_2\) subblock sequences shall consist of the first output bit from the \(W_1\) subblock interleaver, the first output bit from the \(W_2\) subblock interleaver, the second output bit from

### 8.4.9.2.3.4.4 Bit selection

Lastly, bit selection is performed to generate the subpacket. The puncturing block is referred as bits selection in the viewpoint of subpacket generation.

Mother code is transmitted with one of the subpackets. The bits in a subpacket are formed by selecting specific sequences of bits from the interleaved CTC encoder output sequence. The resulting subpacket sequence is a binary sequence of bits for the modulator.

Let

- \( k \) be the subpacket index when IR HARQ is enabled. \( k = 0 \) for the first transmission and increases by one for the next subpacket. \( k = 0 \) when IR HARQ is not used. When there are more than one FEC block in a burst, the subpacket index for each FEC block shall be the same.
- \( N_{EP} \) be the number of bits in the encoder packet (before encoding).
- \( N_{SCH} \) be the number of the concatenated slots for the subpacket defined in Table 500 for the non-HARQ and Chase HARQ CTC scheme defined in 8.4.9.2.3.1 and be the same as the \( N_{sch} \) that is indicated in the Allocation IE for the HARQ CTC scheme defined in 8.4.9.2.3.5.
- \( m_k \) be the modulation order for the \( k \)-th subpacket (\( m_k = 2 \) for QPSK, \( 4 \) for 16-QAM, and \( 6 \) for 64-QAM).
- \( SPID_k \) be the subpacket ID for the \( k \)-th subpacket, (for the first subpacket, \( SPID_{k=0} = 0 \)).

Also, let the scrambled and selected bits be numbered from zero with the 0-th bit being the first bit in the sequence. Then, the index of the \( i \)-th bit for the \( k \)-th subpacket shall be as shown in Equation (117).

\[
S_{k,i} = (F_k + i) \mod (3 \times N_{EP})
\]

where

- \( i = 0 \ldots L_k - 1 \),
- \( L_k = 48 \cdot N_{SCH} \cdot m_k \),
- \( F_k = (SPID_k \cdot L_k) \mod (3 \cdot N_{EP}) \).

The \( N_{EP} \), \( N_{SCH} \), \( m_k \), and \( SPID \) values are determined by the BS and can be inferred by the SS through the allocation size in the DL-MAP and UL-MAP. The above bit selection makes the following possible:

a) The first transmission includes the systematic part of the mother code. Thus, it can be used as the codeword for a burst where the HARQ is not applied or when Chase HARQ is applied.

b) The location of the subpacket can be determined by the SPID itself without the knowledge of previous subpacket. It is very important property for IR HARQ retransmission.

### 8.4.9.2.3.5 Optional IR HARQ support

The procedure of IR-HARQ CTC subpacket generation is as follows: padding, CRC addition, fragmentation, randomization, and CTC encoding. IR-HARQ implementation is optional. The randomization block in 8.4.9.1, the concatenation scheme in 8.4.9.2.3.1, and the interleaving in 8.4.9.3 shall not be applied for the encoding described in this subclause.
8.4.9.2.3.5.1 Padding

MAC PDU (or concatenated MAC PDUs) is a basic unit processed in this channel coding and modulation blocks. When the size of MAC PDU (or concatenated MAC PDUs) is not the element in the allowed set for HARQ, ones are padded at the end of MAC PDU (or concatenated MAC PDUs). The amount of the padding is the same as the difference between the size of the PDU (or concatenated MAC PDUs) and the smallest element in the allowed set that is not less than the size of the PDU (or concatenated MAC PDUs). The padded packet is input into the CRC encoding block.

The allowed set is \{32, 80, 128, 176, 272, 368, 464, 944, 1904, 2864, 3824, 4784, 9584, 14384, 19184, 23984\} bits.

8.4.9.2.3.5.2 CRC encoding

When HARQ is applied to a packet, error detection is provided on the padded packet through a Cyclic Redundancy Check (CRC).

The size of the CRC is 16 bits. CRC16-CCITT, as defined in ITU-T Recommendation X.25, shall be included at the end of the padded packet. The CRC covers both the padded bits and the information part of the padded packet. After the CRC operation, the packet size shall belong to set \{48, 96, 144, 192, 288, 384, 480, 960, 1920, 2880, 3840, 4800, 9600, 14400, 19200, 24000\}.

8.4.9.2.3.5.3 Fragmentation

When the size after the padding and CRC encoding is \(n \times 4800\) bits they are separately encoded by the block of 4800 bits and concatenated as the same order of the separation before modulation. No operation is performed for the packet whose size after the padding and CRC encoding is not more than 4800 bits. The bits output from the fragmentation block are denoted by \(r_1, r_2, ..., r_{N_{EP}}\), and this sequence is defined as encoder packet. \(N_{EP}\) is the number of the bits in an encoder packet and defined as encoder packet size. The values of \(N_{EP}\) are 48, 96, 144, 192, 288, 384, 480, 960, 1920, 2880, 3840, 4800.

8.4.9.2.3.5.4 Randomization

The randomization is performed on each encoder packet; in other words, for each encoder packet, the randomizer shall be initialized independently.

The PRBS generator shall be \(1 + x^{14} + x^{15}\) as shown in Figure 292. Each data byte to be transmitted shall enter sequentially into the randomizer, MSB first. Preambles are not randomized. The seed value shall be
used to calculate the randomization bits, which are combined in an XOR operation with the serialized bit stream of each FEC block.

![PRBS generator of the randomization](image)

The scrambler is initialized with the vector [LSB] 0 1 1 0 1 1 0 0 0 1 0 1 0 1 [MSB].

### 8.4.9.2.3.5.5 CTC encoding and subpacket generation

The CTC encoding and subpacket generation is the same as the operation described in 8.4.9.2.3.1, 8.4.9.2.3.2, 8.4.9.2.3.3, and 8.4.9.2.3.4.

### 8.4.9.2.3.5.6 Modulation order of DL traffic burst

For DL, the modulation order (2 for QPSK, 4 for 16-QAM, and 6 for 64-QAM) shall be set for all the allowed transmission formats as shown in Table 507. The transmission format is given by the $N_{EP}$ (encoding packet size) and the $N_{SCH}$ (number of allotted slots). $N_{EP}$ per an encoding packet is \{144, 192, 288, 384, 480, 960, 1920, 2880, 3840, 4800\}. The $N_{SCH}$ per an encoding packet is \{1, ..., 480\}. In Table 507, the numbers in the first row are $N_{EPS}$, and the numbers in the remaining rows are $N_{SCHs}$ and related parameters. In Table 507, the modulation order is denoted by $MOD$, and it has the values of 2 for QPSK, 4 for 16-QAM, and 6 for 64-QAM. $SCH$ denotes for the number of allocated slots.

The supportable modulation schemes are QPSK, 16-QAM, and 64-QAM. When the $N_{EP}$ and the $N_{SCH}$ are given, the modulation order is determined by the value of $MPR$ (Modulation order Product code Rate). The $MPR$ means the effective number of the information bit transmitted per a subcarrier and is defined by Equation (118).

$$MPR = \frac{N_{EP}}{48 \times N_{SCH}}$$

Then, the modulation order is specified by the following rules:

- If $0 < MPR < 1.5$, then a QPSK (modulation order 2) is used.
- If $1.5 \leq MPR < 3.0$, then a 16-QAM (modulation order 4) is used.
- If $3.0 \leq MPR < 5.4$, then a 64-QAM (modulation order 6) is used.

The effective code rate is equal to $MPR$ divided by the modulation order (i.e., 2 for QPSK).

The information of $N_{EP}$ and $N_{SCH}$ shall be signaled in HARQ MAP. Instead of the actual values of $N_{EP}$ and $N_{SCH}$, the encoded value of $N_{EP}$ ($N_{EP}$ code) and $N_{SCH}$ ($N_{SCH}$ code) shall be used for the signaling. They are
encoded by 4 bits, respectively. The encoding of \( N_{EP} \) (\( N_{EP} \) code) is shown in Table 508. The encoding of \( N_{SCH} \) (\( N_{SCH} \) code) is performed per \( N_{EP} \) value. For each \( N_{EP} \), there are fewer than 16 kinds of \( N_{SCH} \) values, and they are encoded from 0 (the smallest number of slots) to 15 in increasing order. When the number of \( N_{SCH} \) values for a \( N_{EP} \) is smaller than 16, the smallest number of the smallest codes is used. When the fragmentation is applied and the number of the subpackets for an allocation is \( n \), \( n \times N_{EP} \) and \( N_{SCH} \) (the number of slots allocated for a subpacket) should be signaled.

</tbody>
</table>

**NOTE**—In Table 507, the first rate entry is the theoretical rate, and the second rate entry is an approximated rate.

The encoding for \( n \times N_{EP} \) (\( N_{EP} \) code) is also shown in Table 508. The encoded value of \( N_{SCH} \) (\( N_{SCH} \) code) should be interpreted as \( N_{SCH} \) for a subpacket and \( n \times N_{SCH} \) for the whole allocation.

### Table 508—\( N_{EP} \) encoding

| \( N_{EP} \) | 4 | 9 | 14 | 19 | 28 | 38 | 48 | 96 | 192 | 288 | 384 | 480 | 960 | 1920 | 2880 | 3840 | 4800 |
| Encoding | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |

#### 8.4.9.2.3.5.7 Modulation order of UL traffic burst

For UL, the modulation order (2 for QPSK and 4 for 16-QAM) shall be set for all the allowed transmission formats as shown in Table 509. The transmission format is given by the \( N_{EP} \) (encoding packet size) and the
$N_{SCH}$ (number of allocated slots). $N_{EP}$ per an encoding packet is {48, 96, 144, 192, 288, 384, 480, 960, 1920, 2880, 3840, 4800}. The $N_{SCH}$ per an encoding packet is {1...240}. In Table 509, the numbers in the first row are $N_{EP}$s, and the numbers in the remaining rows are $N_{SCH}$s and related parameters. In Table 509, the modulation order is denoted by MOD, and it has the values of two for QPSK, four for 16-QAM. SCH denotes for the number of allocated slots.

The supportable modulation schemes are QPSK and 16-QAM. When the $N_{EP}$ and the $N_{SCH}$ are given, the modulation order is determined by the value of MPR. The MPR means the effective number of the information bit transmitted per subcarrier and is defined by Equation (119).

$$MPR = \frac{N_{EP}}{48 \times N_{SCH}}$$

Then, the modulation order is specified by the following rules:

— If $0 < MPR < 1.5$, then a QPSK (modulation order 2) is used.
— If $1.5 \leq MPR < 3.4$, then a 16-QAM (modulation order 4) is used.

The effective code rate is equal to $MPR$ divided by the modulation order (i.e., 2 for QPSK).

The information of $N_{EP}$ and $N_{SCH}$ shall be signaled in HARQ MAP. Instead of the actual values of $N_{EP}$ and $N_{SCH}$, the encoded value of $N_{EP}$ ($N_{EP}$ code) and $N_{SCH}$ ($N_{SCH}$ code) shall be used for the signaling. They are encoded by 4 bits, respectively. The encoding of $N_{EP}$ ($N_{EP}$ code) is shown in Table 508. The encoding of $N_{SCH}$ ($N_{SCH}$ code) is performed per $N_{EP}$ value. For each $N_{EP}$, there are fewer than 16 kinds of $N_{SCH}$ values, and they are encoded from 0 (the smallest number of slots) to 15 in increasing order. When the number of $N_{SCH}$ values for a $N_{EP}$ is smaller than 16, then the corresponding number of codes is used. When the fragmentation is applied and the number of the subpackets for an allocation is $n$, $n \times N_{EP}$, and $N_{SCH}$ (the number of slots allocated for a subpacket) should be signaled.

The encoding for $n \times N_{EP}$ ($N_{EP}$ code) is also shown in Table 508. The encoded value of $N_{SCH}$ ($N_{SCH}$ code) should be interpreted as $N_{SCH}$ for a subpacket and $n \times N_{SCH}$ for the whole allocation.

### 8.4.9.2.4 Zero tailed convolutional coding (optional)

The convolutional encoder (as described in 8.4.9.2.1) may employ the Zero Tailing technique. In this case, a single 0x00 tail byte is appended at the end of each burst. This tail byte shall be appended after randomization. The convolutional code and the puncturing shall be applied to the whole burst without partitioning it into blocks. The interleaving shall be applied to the coded bits in blocks of size described in 8.4.9.2.
8.4.9.2.5 Low density parity check (LDPC) code (optional)

8.4.9.2.5.1 Code description

The LDPC code is based on a set of one or more fundamental LDPC codes. Each of the fundamental codes is a systematic linear block code. Using the described methods in 8.4.9.2.5.2 Code Rate and Block Size Adjustment, the fundamental codes can accommodate various code rates and packet sizes.

Each LDPC code in the set of LDPC codes is defined by a matrix \( H \) of size \( m \)-by-\( n \), where \( n \) is the length of the code and \( m \) is the number of parity check bits in the code. The number of systematic bits is \( k = n - m \).

The matrix \( H \) is defined as follows:

\[
H = \begin{bmatrix}
P_{0,0} & P_{0,1} & P_{0,2} & \ldots & P_{0,n_2-2} & P_{0,n_2-1} \\
P_{1,0} & P_{1,1} & P_{1,2} & \ldots & P_{1,n_2-2} & P_{1,n_2-1} \\
P_{2,0} & P_{2,1} & P_{2,2} & \ldots & P_{2,n_2-2} & P_{2,n_2-1} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
P_{m_0-1,0} & P_{m_0-1,1} & P_{m_0-1,2} & \ldots & P_{m_0-1,n_2-2} & P_{m_0-1,n_2-1} \\
\end{bmatrix} = P^{H_k}
\]

where \( P_{ij} \) is one of a set of \( z \)-by-\( z \) permutation matrices or a \( z \)-by-\( z \) zero matrix. The matrix \( H \) is expanded from a binary base matrix \( H_b \) of size \( m_b \)-by-\( n_b \), where \( n = z \times n_b \) and \( m = z \times m_b \), with \( z \) an integer \( \geq 1 \). The base matrix is expanded by replacing each 1 in the base matrix with a \( z \)-by-\( z \) permutation matrix, and each 0 with a \( z \)-by-\( z \) zero matrix. The base matrix size \( n_b \) is an integer equal to 24.

The permutations used are circular right shifts, and the set of permutation matrices contains the \( z \times z \) identity matrix and circular right shifted versions of the identity matrix. Because each permutation matrix is specified by a single circular right shift, the binary base matrix information and permutation replacement information can be combined into a single compact model matrix \( H_{bm} \). The model matrix \( H_{bm} \) is the same size as the binary base matrix \( H_b \), with each binary entry \((i,j)\) of the base matrix \( H_b \) replaced to create the model matrix \( H_{bm} \). Each 0 in \( H_b \) is replaced by a blank or negative value (e.g., by \(-1\)) to denote a \( z \times z \) all-zero matrix, and each 1 in \( H_b \) is replaced by a circular shift size \( p(i,j) \geq 0 \). The model matrix \( H_{bm} \) can then be directly expanded to \( H \).

\( H_b \) is partitioned into two sections, where \( H_{b1} \) corresponds to the systematic bits and \( H_{b2} \) corresponds to the parity-check bits, so that \( H_b = \left( \begin{smallmatrix} (H_{b1})_{m_1 \times n_1} & (H_{b2})_{m_2 \times n_2} \end{smallmatrix} \right) \).

Section \( H_{b2} \) is further partitioned into two sections, where vector \( h_b \) has odd weight, and \( H'_{b2} \) has a dual-diagonal structure with matrix elements at row \( i \), column \( j \) equal to 1 for \( i = j, 1 \) for \( i = j+1 \), and 0 elsewhere:

\[
H'_{b2} = \begin{bmatrix}
h_b(0) & 1 & 1 \\
h_b(1) & 0 & 1 \\
\vdots & \ddots & \vdots \\
h_b(m_b-1) & 1 & 1 \\
\end{bmatrix}
\]
The base matrix has $h_b(0) = 1$, $h_b(m_b-1) = 1$, and a third value $h_b(j)$, $0 < j < (m_b-1)$ equal to 1. The base matrix structure avoids having multiple weight -1 columns in the expanded matrix.

In particular, the nonzero submatrices are circularly right shifted by a particular circular shift value. Each 1 in $H_{b2}$ is assigned a shift size of 0, and is replaced by a $z\times z$ identity matrix when expanding to $H$. The two located at the top and the bottom of $h_b$ are assigned equal shift sizes, and the third 1 in the middle of $h_b$ is given an unpaired shift size.

A base model matrix is defined for the largest code length ($n = 2304$) of each code rate. The set of shifts $\{p(i,j)\}$ in the base model matrix are used to determine the shift sizes for all other code lengths of the same code rate. Each base model matrix has $n_b = 24$ columns, and the expansion factor $z_f$ is equal to $n/24$ for code length $n$. Here $f$ is the index of the code lengths for a given code rate, $f = 0, 1, 2, \ldots 18$. For code length $n = 2304$ the expansion factor is designated $z_f = 96$.

For code rates 1/2, 3/4 A and B code, 2/3 B code, and 5/6 code, the shift sizes $\{p(f, i, j)\}$ for a code size corresponding to expansion factor $z_f$ are derived from $\{p(i,j)\}$ by scaling $p(i,j)$ proportionally, as shown in Equation (120).

$$
(f, i, j) = \begin{cases} 
(\lfloor p(i,j) \rfloor, p(i,j) \leq 0) \\
(\lfloor p(i,j) / z_f \rfloor, p(i,j) > 0)
\end{cases}
$$

(120)

where $\lfloor x \rfloor$ denotes the flooring function that gives the nearest integer towards $-\infty$.

For code rate 2/3 A code, the shift sizes $\{p(f, i, j)\}$ for a code size corresponding to expansion factor $z_f$ are derived from $\{p(i,j)\}$ by using a modulo function.

$$
r(f, i, j) = \begin{cases} 
(\lfloor p(i,j) \rfloor, p(i,j) \leq 0) \\
(mod(p(i,j), z_f), p(i,j) > 0)
\end{cases}
$$

Rate 1/2:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| -1 | 94 | 73 | -1 | -1 | -1 | -1 | -1 | 55 | 83 | -1 | -1 | 7 | 0 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 | -1 |

```
8.4.9.2.5.2 Code rate and block size adjustment

The LDPC code flexibly supports different block sizes for each code rate through the use of an expansion factor. Each base model matrix has \( n_b = 24 \) columns, and the expansion factor (\( z \) factor) is equal to \( n/24 \) for code length \( n \). In each case, the number of information bits is equal to the code rate times the coded length \( n \). (See Table 510.)

8.4.9.2.5.3 Packet encoding

The encoding block size \( k \) shall depend on the number of slots allocated and the modulation specified for the current transmission. Concatenation of a number of slots shall be performed in order to make larger blocks of coding where it is possible, with the limitation of not passing the largest block under the same coding rate (the block defined by the 64-QAM modulation). Table 511 specifies the concatenation of slots for different allocations and modulations. The concatenation rule follows the slot concatenation rule for CC (see Table 492) except that for LDPC the concatenation does not depend on the code rate.
For any modulation and FEC rate, given an allocation of $N_{\text{SCH}}$ slots, the following parameters are defined:

- $j_i$: parameter dependent on the modulation and number of antennas in case of spatial multiplexing
- $N_{\text{SCH}}$: number of allocated slots
- $F$: floor($N_{\text{SCH}}/j_i$)
- $M$: $N_{\text{SCH}} \mod j_i$

The slot concatenation rule for convolutional coding in Table 492 is applied, noting that in Table 492 the parameter $n$ is equal to $N_{\text{SCH}}$, the parameter $k$ is equal to $F$, and the parameter $m$ is equal to $M$. The parameter $j_i$ for LDPC is determined as shown in Table 511.

Control information and packets that result in a codeword size $n$ of less than 576 bits are encoded using convolutional coding with appropriate code rates and modulation orders, as described in 8.4.9.2.1.

### 8.4.9.3 Interleaving

All encoded data bits shall be interleaved by a block interleaver with a block size corresponding to the number of coded bits per the encoded block size $N_{\text{cbps}}$. The interleaver is defined by a two-step permutation. The first ensures that adjacent coded bits are mapped onto nonadjacent subcarriers. The second permutation insures that adjacent coded bits are mapped alternately onto less or more significant bits of the constellation, thus avoiding long runs of lowly reliable bits.

Let $N_{\text{cpc}}$ be the number of coded bits per subcarrier, i.e., 2, 4, or 6 for QPSK, 16-QAM, or 64-QAM, respectively. Let $s = N_{\text{cpc}}/2$. Within a block of $N_{\text{cbps}}$ bits at transmission, let $k$ be the index of the coded bit before the first permutation, $m_k$ be the index of that coded bit after the first and before the second permutation and let $j_k$ be the index after the second permutation, just prior to modulation mapping, and $d$ be the modulo used for the permutation.

The first permutation is defined by Equation (121):

$$m_k = (N_{\text{cbps}}/d) \cdot k \mod d + \text{floor}(k/d) \quad k = 0, 1, \ldots, N_{\text{cbps}} - 1 \quad d = 16 \quad (121)$$

The second permutation is defined by Equation (122).

$$j_k = s \cdot \text{floor}(m_k/s) + (m_k + N_{\text{cbps}} - \text{floor}(d \cdot m_k/N_{\text{cbps}})) \mod s \quad k = 0, 1, \ldots, N_{\text{cbps}} - 1 \quad d = 16 \quad (122)$$

The de-interleaver, which performs the inverse operation, is also defined by two permutations. Within a received block of $N_{\text{cbps}}$ bits, let $j$ be the index of a received bit before the first permutation; $m_j$ be the index of that bit after the first and before the second permutation; and let $k_j$ be the index of that bit after the second permutation, just prior to delivering the block to the decoder.

The first permutation is defined by Equation (123).

<table>
<thead>

<tr>
<td>8</td>
<td>4</td>
<td>2</td>
<td>2</td>
<td>64-QAM</td>
</tr>
</tbody>
</table>

Table 511—Parameter $j_i$ for LDPC
The second permutation is defined by Equation (124).

\[ k_j = d \cdot m_j - (N_{\text{chps}} - 1) \cdot \text{floor}(d \cdot m_j / N_{\text{chps}}) \quad j = 0, 1, \ldots, N_{\text{chps}} - 1 \quad d = 16 \quad (124) \]

The first permutation in the de-interleaver is the inverse of the second permutation in the interleaver, and conversely.

### 8.4.9.3.1 Optional interleaver for convolutional coding

For the convolutional coding optional interleaver, the interleaver structure is as defined in 8.4.9.3. The value of \( d \) in Equation (121) through Equation (124) shall be set to \( 16 \times n \) for the DL and \( 16 \times n \) for the UL, where \( n \) is the number of allocated slots per FEC block.

### 8.4.9.4 Modulation

#### 8.4.9.4.1 Subcarrier randomization

The PRBS generator depicted hereafter shall be used to produce a sequence, \( w_k \) (see Figure 293). The polynomial for the PRBS generator shall be \( X^{11} + X^9 + 1 \).

![Figure 293—PRBS generator for pilot modulation](image)

The value of the pilot modulation, on subcarrier \( k \), shall be derived from \( w_k \).

The initialization vector of the PRBS generator for both UL and DL shall be designated \( b_{10..0} \) so that

- \( b_{0..4} = \) 5 LSBs of IDcell as indicated by the frame preamble in the first DL zone and in the DL AAS zone with Diversity_Map support, DL_Permbase following STC_DL_Zone_IE()
- \( b_{5..6} = \) 5 LSBs of DL_Permbase following AAS DL_IE without Diversity_Map support in the DL
- \( b_{7..10} = \) IDcell (as determined in the preamble) in the UL
  - For DL and UL, \( b_0 \) is MSB, and \( b_4 \) is LSB.
- \( b_{5..6} = \) Set to the segment number \( + \) 1 as indicated by the frame preamble in the first DL zone and in the DL AAS zone with Diversity_Map support, PRBS_ID as indicated by the STC DL Zone IE or AAS DL_IE without Diversity_Map support in other DL zones
  - \( b_{5..6} = 0b11 \) in the UL
  - For DL and UL, \( b_5 \) is MSB, and \( b_6 \) is LSB.
- \( b_{7..10} = \) 0b1111 (all ones) in the downlink and four least significant bits of the Frame Number in the uplink.
  - For TDD uplink, the Frame Number used is the one in which the UL subframe is transmitted. For FDD/H-FDD uplink, the Frame Number is the one in which the UL subframe is transmitted, that is, the Frame Number of the frame relevant to the UL-MAP.
  - For downlink and uplink, \( b_7 \) is MSB and \( b_{10} \) is LSB, respectively.
For example, should the initialization vector of the PRBS generator be \( b_{10}\ldots b_0 = 10101010101 \), the initializations result in the sequence \( w_k = 10101010101000000000 \ldots \) in the UL. The PRBS generator shall be clocked \( n \) times, \( n = \text{Symbol Offset mod 32} \), before the generated output is applied to the subcarriers, where the symbol offset is counted from the first symbol in each zone as zero in the DL except DL AAS zone with Diversity Map support where the symbol offset is counted from the first symbol of the first DL zone as zero and from allocation start time in the UL (i.e., the first symbol in the UL subframe is indexed 0). The PRBS generator output shall not be applied to the subcarriers of the mid-amble (if present). As a result, the PRBS shall be used so that its \( n \)-th output bit will coincide with the first usable subcarrier as defined for the zone in which the symbol resides. The output bit shall be counted from zero. Subcarriers belonging to UL allocations with UIUC = 12 or UIUC = 13 shall not be randomized. A new value shall be generated by the PRBS generator for every subcarrier up to the highest numbered usable subcarrier, in order of physical subcarriers, including the DC subcarrier and usable subcarriers that are not allocated.

Consider DL PUSC. Let \( w_0, w_1, w_2, \ldots \) be the bits generated after loading the correct initialization vector. The subcarriers of the first symbol in the zone (with symbol offset of zero) shall use the bits \( w_0, w_1, w_2, \ldots, w_{1680} \). The subcarriers of the second symbol (with symbol offset of one) shall use the bits \( w_1, w_2, w_3, \ldots, w_{1681} \).

### 8.4.9.4.2 Data modulation

After the repetition block, the data bits are entered serially to the constellation mapper. Gray-mapped QPSK and 16-QAM (as shown in Figure 294) shall be supported, whereas the support of 64-QAM is optional. The constellations (as shown in Figure 294) shall be normalized by multiplying the constellation point with the indicated factor \( c \) to achieve equal average power.

![Figure 294—QPSK, 16-QAM, and 64-QAM constellations](image-url)
Per-allocation adaptive modulation and coding shall be supported in the DL. The UL shall support different modulation schemes for each SS based on the MAC burst configuration messages coming from the BS. Complete description of the MAC/PHY support of adaptive modulation and coding is provided in 6.3.7.

Each $M$ interleaved bits ($M = 2, 4, 6$) shall be mapped to the constellation bits $b(M - 1) - b0$ in MSB-first order (i.e., the first bit shall be mapped to the higher index bit in the constellation).

The constellation-mapped data shall be subsequently modulated onto the allocated data subcarriers. Before mapping the data to the physical subcarriers (i.e., after applying the subcarrier permutation), each subcarrier shall be multiplied by the factor $2 \times (1/2 - w_k)$ according to the subcarrier physical index, $k$.

The operation shall be also applied for the subcarriers for the fast-feedback and ACK channels except the ranging.

In the DL, data subcarriers that belong to slots that are not allocated in the DL-MAP shall not be transmitted (zero energy). Data subcarriers that are part of a gap allocation (DIUC = 13) shall be modulated at the BS’s discretion. In the DL, such subcarriers that belong to the allocated slots for a burst but are not modulated shall not be transmitted (zero energy).

8.4.9.4.3 Pilot modulation

For the mandatory tile structure in the UL and for the TUSC1/TUSC2 structures in the DL, pilot subcarriers shall be inserted into each data burst in order to constitute the symbol, and they shall be modulated according to their subcarrier location within the OFDMA symbol.

The pilot subcarriers shall be modulated according to Equation (125).

$$
\begin{align*}
\text{Re}\{c_k\} &= 2\left(\frac{1}{2} - w_k\right) \\
\text{Im}\{c_k\} &= 0
\end{align*}
$$

(125)

In all permutations except UL PUSC, downlink TUSC1, and the DL and UL STC permutations/modes, each pilot shall be transmitted with a boosting of 2.5 dB over the average non-boosted power of each data tone. These pilot subcarriers shall be modulated according to Equation (126).

$$
\begin{align*}
\text{Re}\{c_k\} &= \frac{8}{3}\left(\frac{1}{2} - w_k\right) \cdot p_k \\
\text{Im}\{c_k\} &= 0
\end{align*}
$$

(126)

where

- $p_k$ is the pilot’s polarity (as described in 8.4.6.3.3) for SDMA allocations in AMC AAS zone
- $p$ is 1 otherwise

In the DL, for PUSC, PUSC-ASCA FUSC, AMC, and optional FUSC permutations, all pilots (of the segment, in case of PUSC and AMC) shall be modulated, regardless of whether all the subchannels are allocated in the DL-MAP except for AMC and PUSC-ASCA permutations in AAS zone or in a zone using Dedicated pilots, where the BS shall not modulate the pilots that belong in bins or slots that are not allocated in the DL-MAP or are allocated as gaps (DIUC = 13).

In a DL STC zone, the per pilot tone power is 5.5 dB above the per data tone power for each transmit antenna.
In UL STC and collaborative SM, the per pilot tone power is 3 dB above the per data tone power for each transmit antenna for PUSC, and 5.5 dB above the per data tone power for each transmit antenna for AMC.

**8.4.9.4.3.1 Preamble pilot modulation**

The pilots in the DL preamble shall follow the instructions in 8.4.6.1.1, and shall be modulated according to Equation (127):

\[
\begin{align*}
\text{Re}\{\text{PreamblePilotsModulated}\} &= 4 \cdot \sqrt{2} \cdot \left( \frac{1}{2} \cdot W_k \right) \\
\text{Im}\{\text{PreamblePilotsModulated}\} &= 0
\end{align*}
\]

Subcarriers for UL and DL AAS preambles shall follow the instructions in 8.4.4.7.4.1 and 8.4.4.7.4.2, and shall be modulated according to Equation (128).

\[
\begin{align*}
\text{Re}\{c_k\} &= 2 \cdot \left( \frac{1}{2} - P_k \right) \\
\text{Im}\{c_k\} &= 0
\end{align*}
\]

where \( P_k \) is the AAS preamble sequence defined by Equation (57) (see 8.4.4.7.4.1 for DL AAS preambles and 8.4.4.7.4.2 for UL AAS preambles).

These AAS preamble subcarriers may further be modified by the UL and DL PHY modifiers as defined in 8.4.5.3.11 and 8.4.5.4.12. After application of any PHY modifiers, the \( c_k \) values are multiplied by the factor \( 2 \times \left( \frac{1}{2} - w_k \right) \).

**8.4.9.4.3.2 Ranging pilot modulation**

The BPSK modulation on the ranging transmissions, real and imaginary parts, is defined by Equation (129).

\[
\begin{align*}
\text{Re}\{c_k\} &= 2 \cdot (1/2 - C_k) \\
\text{Im}\{c_k\} &= 0
\end{align*}
\]

where \( c_k \) is the \( k \)-th subcarrier in order of increasing frequency of the Ranging Channel, and \( C_k \) is the \( k \)-th bit of the code generated according to 8.4.7.3.

**8.4.9.4.4 Example of OFDMA UL CC encoding**

An example of one burst of OFDMA uplink using mandatory structure is provided, illustrating each process from randomization through subcarrier modulation. The scenario parameters are as follows:

1) OFDM symbol number start = 0
2) Number of time slots in UL allocation = 2
3) Starting Logical Slot = 16 (mapped onto physical subchannel 16 in the first time slot and physical subchannel 29 in the second time slot due to subchannel rotation)
4) IDcell = 5
5) UL_Permbase = 5
6) Modulation = QPSK
7) Coding scheme = Convolutional coding
8) Coding rate = 1/2
9) Frame Number = 5
Input Data (Hex):
AC BC D2 11 4D AE 15 77 C6 DB F4 C9

Constellation Mapping (data shall be transformed to constellation values: I value/Q value. The value 0.707 represents sqrt(2)/2):

\[
\begin{align*}
+0.707/-0.707, & \quad +0.707/+0.707, & \quad -0.707/+0.707, & \quad -0.707/-0.707, & \quad +0.707/+0.707, \\
+0.707/-0.707, & \quad +0.707/+0.707, & \quad -0.707/-0.707, & \quad -0.707/+0.707, & \quad +0.707/-0.707, \\
-0.707/-0.707, & \quad -0.707/-0.707, & \quad +0.707/-0.707, & \quad -0.707/+0.707, & \quad +0.707/+0.707, \\
+0.707/-0.707, & \quad +0.707/+0.707, & \quad -0.707/-0.707, & \quad -0.707/+0.707, & \quad +0.707/+0.707, \\
-0.707/-0.707, & \quad -0.707/-0.707, & \quad +0.707/-0.707, & \quad -0.707/+0.707, & \quad +0.707/+0.707, \\
-0.707/-0.707, & \quad -0.707/-0.707, & \quad +0.707/-0.707, & \quad -0.707/+0.707, & \quad +0.707/+0.707, \\
+0.707/-0.707, & \quad +0.707/+0.707, & \quad -0.707/-0.707, & \quad -0.707/+0.707, \quad +0.707/+0.707
\end{align*}
\]

These results shall be mapped onto subcarriers and multiplied by PN [assuming the use of logical data subchannel 16, mapped onto physical subchannel 16 in the first time slot and to physical subchannel 29 at the second time slot, structure includes pilots and is in the structure of (Symbol Number, Subcarrier Index, I value/Q value)]:

\[
\begin{align*}
(0.448,+1/0)(0.449,+0.707/+0.707)(0.450,-0.707/-0.707)(0.451,-1/0)(0.512,-1/0)(0.513,-0.707/
+0.707)(0.514,+0.707/-0.707)(0.515,-1/0)(0.984,-1/0)(0.985,+0.707/+0.707)(0.986,+0.707/-
0.707)(0.987,-1/0)(0.1189,+1/0)(0.1190,-0.707/-0.707)(0.1191,+0.707/+0.707)(0.1192,-1/0)
(0.1505,-1/0)(0.1506,-0.707/-0.707)(0.1507,-0.707/-0.707)(0.1508,+1/0)(0.1753,-1/0)(0.1754,-
0.707/-0.707)(0.1755,+0.707/-0.707)(0.1756,+1/0)(1.448,-0.707/-0.707)(1.449,+0.707/-
0.707)(1.450,+0.707/-0.707)(1.451,-0.707/-0.707)(1.512,-0.707/+0.707)(1.513,-0.707/-
0.707)(1.514,+0.707/-0.707)(1.515,-0.707/-0.707)(1.984,+0.707/+0.707)(1.985,+0.707/
+0.707)(1.986,+0.707/+0.707)(1.987,+0.707/+0.707)(1.1189,+0.707/-0.707)(1.1190,-0.707/-
0.707)(1.1191,+0.707/+0.707)(1.1192,-0.707/-0.707)(1.1505,+0.707/+0.707)(1.1506,+0.707/
+0.707)(1.1507,-0.707/-0.707)(1.1508,-0.707/-0.707)(1.1753,-0.707/-0.707)(1.1754,-0.707/-
0.707)(1.1755,+0.707/+0.707)(1.1756,+0.707/-0.707)(2.448,+1/0)(2.449,+0.707/+0.707)(2.450,-
0.707/-0.707)(2.451,-1/0)(2.512,-1/0)(2.513,-0.707/-0.707)(2.514,-0.707/+0.707)(2.515,-1/0)
(2.984,+1/0)(2.985,+0.707/+0.707)(2.986,-0.707/+0.707)(2.987,-1/0)(2.1189,+1/0)(2.1190,-0.707/
\]
8.4.9.5 Repetition

Repetition coding can be used to further increase signal margin over the modulation and FEC mechanisms. In the case of repetition coding, \( R = 2, 4, \) or 6, the number of allocated slots (\( N_s \)) shall be a whole multiple of the repetition factor \( R \) for UL. For the DL, the number of the allocated slots (\( N_s \)) shall be in the range of \( [K \times R, K \times R + (R - 1)] \), where \( K \) is the number of the required slots before applying the repetition scheme. For example, when the required number of slots before the repetition is 10 (\( = K \)) and the repetition of \( R = 6 \) shall be applied for the burst transmission, then the number of the allocated slots (\( N_s \)) for the burst can be from 60 slots to 65 slots.

The binary data that fits into a region that is repetition coded is reduced by a factor \( R \) compared to a nonrepeated region of the \( (\left\lfloor N_s / R \right\rfloor \times R) \) slots with the same size and FEC code type. After FEC and bit-interleaving, the data is segmented into slots, and each group of bits designated to fit in a slot shall be repeated \( R \) times to form \( R \) contiguous slots following the normal slot ordering that is used for data mapping. The actual constellation data can be different because of the subcarrier randomization as defined by 8.4.9.4.1. This repetition scheme applies only to QPSK modulation; it can be applied in all coding schemes except Optional IR HARQ with CTC defined in 8.4.9.2.3.5.

8.4.9.6 Zone boosting

When the usage of the subchannels in a DL zone is limited by a bitmap, all subcarriers including pilot subcarriers in the corresponding zones shall be boosted. The amount of subcarrier boosting is the ratio of the number of \( N_{used} \) subcarriers, excluding the DC subcarrier, to the number of the allowed subcarriers. The “allowed subcarriers” refers to the data and pilot subcarriers that are allowed to be used in the zone by the bitmap. When zone boosting is applied, the amount of additional subchannel boosting, as specified by the boosting field in the DL-MAP IE that can be applied, shall not exceed 9 dB minus the amount of zone boosting. The bitmaps that limit subcarrier usage are the “Used subchannel bitmap” in the FCH that applies to the first DL PUSC zone and to PUSC zones in which Use all SC field is set to ‘0’, and the “DL AMC allocated physical bands bitmap”, “TUSC1 permutation active subchannels bitmap”, and “TUSC2 permutation active subchannels bitmap” TLVs in the DCD.

The total transmit power for any symbol in a given STC zone without dedicate pilots shall not be more than:

\[
P_{\text{tx_Preamble}} = 4.2 + 10 \cdot \log_{10}(\text{Num_STC_Antennas}) \quad \text{dBm}
\]
where $\text{Num\_STC\_antennas}$ is the number of STC antennas defined in the STC_DL_IE() and $P_{\text{tx\_Preamble}}$ is the total power transmitted in the preamble symbol in dBm. Other than this requirement, the power level in the STC zones without dedicated pilots in a frame is unrelated to the power level in the non-STC zones in a frame.

### 8.4.9.7 Multiple HARQ (optional)

Supported Multiple HARQ modes may be enabled for any of the existing FEC modes. A change in the HARQ mode is signaled using the HARQ Compact DL-MAP IE format for switch HARQ mode (see 6.3.2.3.38.6.7). The definitions of the HARQ modes are defined in Table 512.

#### Table 512—HARQ modes definition

<table>
<thead>
<tr>
<th>HARQ mode</th>
<th>Definition</th>

#### 8.4.9.7.1 Generic chase HARQ

When chase combining HARQ is enabled for a particular MS, the HARQ MAP shall be used to signal the allocation and the HARQ Control IE shall use the generic chase allocation format. The encoding of the companded subchannel field is defined in Table 513. Concatenation rules for each respective coding mode are applied as defined for non-HARQ transmissions.

</table>
When HARQ is applied to a packet, error detection is provided on the HARQ packet through a Cyclic Redundancy Check (CRC).

The size of the CRC is 16 bits. CRC 16-CCITT, as defined in ITU-T Recommendation X.25, shall be included at the end of the HARQ packet and after the padding bits.

8.4.9.7.2 CC-IR HARQ

When CC-IR is enabled for a particular SS, the HARQ_MAP shall be used to signal the allocation and the HARQ Control IE shall use the CC-IR allocation format. The encoding of the companded subchannel field is identical to generic chase HARQ and is defined in Table 513. Concatenation rules for each respective coding mode are applied as defined for non-HARQ transmissions.

8.4.10 Control mechanisms

8.4.10.1 Synchronization

8.4.10.1.1 Network synchronization

For TDD and FDD realizations, it is recommended (but not required) that all BSs be time synchronized to a common timing signal. In the event of the loss of the network timing signal, BSs shall continue to operate and shall automatically resynchronize to the network timing signal when it is recovered. The synchronizing reference shall be a 1 pps timing pulse and may also include a 10 MHz frequency reference. These signals are typically provided by a GPS receiver.

For both FDD and TDD realizations, frequency references derived from the timing reference may be used to control the frequency accuracy of BSs provided that they meet the frequency accuracy requirements of 8.4.15. This applies during normal operation and during loss of timing reference.

8.4.10.1.2 SS synchronization

For any duplexing, all SSs shall acquire and adjust their timing so that all UL OFDMA symbols arrive time coincident at the BS to a accuracy of ± 25% of the minimum guard-interval or better.

8.4.10.2 Ranging

Ranging for time and power is performed during two phases of operation: during (re)registration and when synchronization is lost; and second, during FDD or TDD transmission on a periodic basis.

During registration, a new subscriber registers using the random access channel, and if successful, is entered into a ranging process under control of the BS. The ranging process is cyclic in nature where default time

<table>

</tr>
</tbody>
</table>
and power parameters are used to initiate the process followed by cycles where (re)calculated parameters are used in succession until parameters meet acceptance criteria for the new subscriber. These parameters are monitored, measured, and stored at the BS, and transmitted to the subscriber unit for use during normal exchange of data. During normal exchange of data, the stored parameters are updated in a periodic manner based on configurable update intervals to ensure changes in the channel can be accommodated. The update intervals shall vary in a controlled manner on a subscriber unit by subscriber unit basis.

Ranging on reregistration follows the same process as new registration.

8.4.10.3 Power control

In situations where the subcarrier power specified by power control mechanisms indicate that the transmit power for a given transmission would exceed the maximum transmit power for the specified MCS, the transmit power shall be limited to the maximum allowed. The MS shall evaluate the data allocation transmit power for each zone independently. Within each zone, all data allocations that are not overlapping in time shall be scaled by the same factor such that the OFDMA symbol with the largest power is limited to the maximum allowed. Regions defined by UIUC=0,12,13 and extended UIUC2=8 that do not overlap data allocations on any OFDMA symbol may be scaled independently of data allocations. UIUC 13 regions used for Sounding Zone allocations shall be scaled independently of data allocations, CQI, ranging and HARQ-ACK allocations if such region contains multiple symbols, each symbol shall be scaled independently.

A power control algorithm shall be supported for the UL channel with both an initial calibration and periodic adjustment procedure without loss of data. The BS should be capable of providing accurate power measurements of the received burst signal. This value can then be compared against a reference level, and the resulting error can be fed back to the SS in a calibration message coming from the MAC. The power control algorithm shall be designed to support power attenuation due to distance loss or power fluctuations at rates of at most 30 dB/s with depths of at least 10 dB for fixed deployment. The exact algorithm implementation is vendor-specific. The total power control range consists of both a fixed portion and a portion that is automatically controlled by feedback. The power control algorithm shall take into account the interaction of the RF power amplifier with different burst profiles. For example, when changing from one burst profile to another, margins should be maintained to prevent saturation of the amplifier and to prevent violation of emissions masks.

A transmitting SS shall maintain the same transmitted power density regardless of the number of subchannels assigned, unless the maximum power level is reached. In other words, when the number of active subchannels allocated to a user is reduced, the total transmitted power shall be reduced proportionally by the SS, without additional power control messages. When the number of subchannels is increased, the total transmitted power shall also be increased proportionally. However, the transmitted power level shall not exceed the maximum levels dictated by signal integrity considerations and regulatory requirements. The SS shall interpret power control messages as the required changes to the transmitted power density.

To maintain at the BS a power density consistent with the modulation and FEC rate used by each SS, the BS may change the SS TX power, through power correction messages, as well as the SS-assigned modulation and FEC rate. When the MS transmits in regions of any UIUCs, the SS shall use a temporary TX power value set according to Equation (131) (in decibels).

\[
P_{\text{new}} = P_{\text{last}} + (C/N_{\text{new}} - C/N_{\text{last}}) - (10 \log_{10}(R_{\text{new}}) - 10 \log_{10}(R_{\text{last}})) + \text{Offset} \tag{131}
\]

where

- \( P_{\text{new}} \) = the power of the new UL burst in the current UL frame
- \( C/N_{\text{new}} \) = normalized \( C/N \) for the new UL burst in the current UL frame
- \( R_{\text{new}} \) = repetition factor \( R \) for the new UL burst in the current UL frame
\[ P_{\text{last}} = \text{the power of the burst with the maximum value of } (C/N - 10\log_{10}(R)) \text{ in the most recently transmitted UL frame} \]

\[ C/N_{\text{last}} = \text{normalized } C/N \text{ associated with } P_{\text{last}} \text{ (thus referring to the burst with the maximum value of } (C/N - 10\log_{10}(R)) \text{ in the most recently transmitted UL frame)} \]

\[ R_{\text{last}} = \text{repetition factor } R \text{ associated with } P_{\text{last}} \text{ (thus referring to the burst with the maximum value of } (C/N - 10\log_{10}(R)) \text{ in the most recently transmitted UL frame)} \]

\[ \text{Offset} = \text{an accumulation of power correction terms sent by the BS since the last transmission} \]

where the power is per subcarrier power.

Initial terms \( P_{\text{new}}, P_{\text{last}}, C/N_{\text{new}}, C/N_{\text{last}}, R_{\text{new}}, \) and \( R_{\text{last}} \) in closed loop power control Equation (131) are obtained from the ranging CDMA code transmission. That is the initial term \( P_{\text{last}} \) is the transmitted ranging power (if an adjustment of RNG-RSP exists, then the adjustment of RNG-RSP is applied), \( C/N_{\text{last}} \) is the \( C/N \) of ranging CDMA code in the Table 515 (Normalized \( C/N \) per modulation) or Normalized \( C/N \) override in the UCD, and \( R_{\text{last}} \) is zero.

### Table 515—Normalized \( C/N \) per modulation for sounding transmission only

<table>
<thead>
<tr>
<th>Modulation/ FEC rate</th>
<th>Normalized ( C/N )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sounding transmission</td>
<td>9</td>
</tr>
</tbody>
</table>
Initial terms $P_{\text{new}}$, $C/N_{\text{new}}$, and $R_{\text{new}}$ are those of the first UL burst transmission with UIUC = 1~10.

For the periodic ranging, once MS sends periodic ranging code and fails to receive RNG-RSP, MS shall adjust its Tx power for the subsequent periodic ranging codes transmission up to $P_{TX, IR, MAX}$ (6.3.9.5.1). For the BR ranging, once MS sends BR ranging code and fails to receive CDMA allocation IE or RNG-RSP, MS shall adjust its Tx power for the subsequent BR ranging codes transmission up to $P_{TX, IR, MAX}$ (6.3.9.5.1).

If MS has UL HARQ connection, the normalized C/N value for HARQ bursts can be adjusted referencing to non HARQ bursts. The power offset is defined in UCD TLV of “Relative_Power_Offset_for_UL_HARQ_burst.” If this TLV exists in the UCD, then the power offset shall be added to the C/N value in Table 514 in case the transmission is HARQ.

When the MS transmits an UL burst containing a MAC management message (PDUs that have Basic CID, Primary management CID, or Secondary management CID), the transmit power for the burst shall be boosted by the value indicated by “Relative Power Offset for UL Burst Containing MAC Management Message” in the UCD.

The MS shall not change its power control mode during sleep mode. The MS shall not change its power control mode upon exit from sleep mode. In case of network re-entry from idle mode, the MS should use the closed loop power control mode upon completion of the initial ranging until it receives PMC_RSP message from BS.

8.4.10.3.1 Closed-loop power control

The SS shall report the maximum available power and the normalized transmitted power. These parameters may be used by the BS for optimal assignment of coding schemes and modulations and also for optimal allocation of subchannels. The algorithm is vendor-specific. The maximum available power may be reported in SBC-REQ. The current transmitted power shall also reported in the REP-RSP message if the relevant flag in the REP-REQ message has been set.

The current transmitted power is the power of the burst that carries the message. The maximum available power is reported for QPSK QAM-16 and QAM-64 constellations. The current transmitted power and the maximum power parameters are reported in dBm. The parameters are quantized in 0.5 dBm steps ranging from $-64$ dBm (encoded 0x00) to $63.5$ dBm (encoded 0xFF) for maximum available power and $-84$ dBm (encoded 0x00) to $43.5$ dBm (encoded 0xFF) for current transmitted power as defined in 11.8.3.2 and 11.1.1 respectively. Values outside this range shall be assigned the closest extreme. SSs that do not support QAM64 shall report the value of 0x00 in the maximum QAM-64 power field.

8.4.10.3.2 Optional open-loop power control

When the open-loop power control is supported and the UL power control mode is changed to open-loop power control by PMC_RSP, the power per a subcarrier shall be maintained for the UL transmission as follows. This open-loop power control shall be applied for the all UL bursts. See Equation (132).

$$P(dBm) = L + C/N + NI - 10 \times \log_{10}(R) + \text{Offset}_{SS} + \text{Offset}_{BS}$$

(132)

where

- $P$ is the TX power level (dBm) per a subcarrier for the current transmission, including MS Tx antenna gain.
- $L$ is the estimated average current UL propagation loss. It shall include SS Tx antenna gain and path loss, but exclude the BS Rx antenna gain.
C/N is the Normalized C/N of the modulation/FEC rate for the current transmission, as appearing in Table 514. Table 514 can be modified by UCD (Normalized C/N override or Normalized C/N override 2).

R is the number of repetitions for the modulation/FEC rate.

NI is the estimated average power level (dBm) of the noise and interference per a subcarrier at BS, not including BS Rx antenna gain.

Offset_SS_perSS is the correction term for SS-specific power offset. It is controlled by SS. Its initial value is zero.

Offset_BS_perSS is the correction term for SS-specific power offset. It is controlled by BS with power control messages. When Offset_BS_perSS is set through the PMC_RSP message, it shall include BS Rx antenna gain.

The estimated average current UL propagation loss, L, shall be calculated based on the total power received on the active subcarriers of the frame preamble, and with reference to the BS_EIRP parameter sent by the BS.

The default normalized C/N values per modulation are given by Table 514. The operating parameters BS_EIRP is signaled by a DCD message (see Table 575) and NI is signaled by “UL noise and interference level IE” (8.4.5.3.19).

Additionally, the BS controls the Offset_BS_perSS using PMC_RSP message (6.3.2.3.54) to override the Offset_BS_perSS value, or using RNG-RSP (6.3.2.3.6), Fast Power Control (FPC) message (6.3.2.3.34), Power Control IE (8.4.5.4.5) and UL-MAP Fast Tracking IE (8.4.5.4.20) to adjust the Offset_BS_perSS value. The accumulated power control value shall be used for Offset_BS_perSS.

MS shall reflect the amount of power adjusted by itself, during ranging due to the failure in receiving a response to the CDMA code transmitted (6.3.9.5.1, 8.4.10.3), to the Offset_BS_perSS as a correction term for the power offset.

The Offset_BS_perSS can be updated using relative or fixed form (as a function of the relevant adjustment commands used). Fixed form is used when the parameter is obtained from a PMC_RSP message. In this case, the SS should replace the old Offset_BS_perSS value by the new Offset_BS_perSS sent by the BS. With all other messages mentioned in the previous paragraph, relative form is used. In this case, MS should increase and decrease the Offset_BS_perSS according to the offset value sent by BS.

The actual power setting shall be quantized to the nearest implementable value, subject to the specification (8.4.13.1). For each transmission, the SS shall limit the power, as required to satisfy the spectral masks and EVM requirements.

a) Passive UL open-loop power control. In passive UL open-loop power control with Offset_SS_perSS retention (i.e., ‘Power control mode change = 0b10’ indicated by PMC_REQ/RSP message), the SS shall set Offset_SS_perSS as described below in the event of power control mode change from closed loop to open loop, and modify the TX power value using Equation (133).

\[
\text{Offset_SS_perSS} = P_{Tx,CL\text{-}last} - (L_{OL\text{-}init} + NI_{OL\text{-}init}) - C/N_{CL\text{-}last} + 10\log_{10}(R_{CL\text{-}last})
\]  

(133)

where

- \( P_{Tx, CL\text{-}last} \) MS transmit power level used in the last transmission in closed loop power control mode.
- \( L_{OL\text{-}init} \) Path-loss value estimated at MS during power control mode change from closed loop to open loop.
— $NI_{OL\_init}$ Latest NI value transmitted in UL Noise and Interference Level IE prior to mode change to open loop power control.
— $C/N_{CL\_last}$ Normalized $C/N$ according to modulation and FEC used in the last transmission in closed loop power control mode.
— $R_{CL\_last}$ Repetition factor for the modulation and FEC scheme used in the last transmission in closed loop power control mode.

The above $Offset\_SS_{perSS}$ shall be calculated only once during the power control mode change from closed loop to open loop. Therefore the $Offset\_SS_{perSS}$ value will remain constant unless another power control mode change is executed.

b) Active UL open-loop power control. An alternative way is that the SS may adjust $Offset\_SS_{perSS}$ value within a range. See Equation (134).

\[
Offset\_Bound\_lower \leq Offset\_SS_{perSS} \leq Offset\_Bound\_upper
\]

where

$Offset\_Bound\_upper$ is the upper bound of $Offset\_SS_{perSS}$

$Offset\_Bound\_lower$ is the lower bound of $Offset\_SS_{perSS}$

Or in case ARQ is enabled at some UL connections, the $Offset\_SS_{perSS}$ may be updated automatically based on the Ack/Nack within the range as specified by Equation (135). The specific algorithm is described as follows (in dB):

\[
\begin{align*}
\text{if NAK is received} & \quad Offset\_SS_{perSS} = Offset\_SS_{perSS} + UP\_STEP \\
\text{else if ACK is received} & \quad Offset\_SS_{perSS} = Offset\_SS_{perSS} - DOWN\_STEP \\
\text{else where} & \quad Offset\_SS_{perSS} = Offset\_SS_{perSS}
\end{align*}
\]

where

$UP\_STEP$ is the up adjustment step as specified by SS-Specific Up Power Offset Adjustment Step TLV

$DOWN\_STEP$ is the down adjustment step as specified by SS-Specific Down Power Offset Adjustment Step TLV

The operating parameters $UP\_STEP$, $DOWN\_STEP$, $Offset\_Bound\_upper$, $Offset\_Bound\_lower$ are signaled by a dedicated UCD message TLV.

8.4.10.3.2.1 UL Tx power and Headroom transmission condition

If the MS supports open loop power control, it shall support the BR and UL Tx power report header (6.3.2.1.2.1.2).

During initial network entry and full network re-entry, if TLV 196 (TX Power Report) is present in the UCD and the conditions of Equation (136) are met, the SS shall begin reporting TX power status after the RNG-RSP is received from the BS and before the DSA message is sent. For handover or idle mode re-entry, if TLV 196 (TX Power Report) is present in the UCD and the conditions of Equation (136) are met, the SS should begin reporting transmission power status immediately after the RNG-RSP is received. Optimized re-entry requires the SS to confirm that it received the RNG-RSP by sending a BW Request or other UL indication. The SS should use the BW Request and TX Power report header to confirm reception of the RNG-RSP and to provide SS transmission power status (enabling the BS to immediately allocate UL bandwidth). The SS shall report TX power status using the BR and UL Tx power report header.
(6.3.2.1.2.1), the PHY channel report header (6.3.2.1.2.1.5) or the UL Tx power report extended subheader
(6.3.2.2.7.5).

\[
|M_{\text{avg}}(n_{\text{last}}) - M_{\text{avg}}(n)| \geq \text{Tx\_Power\_Report\_Threshold} \quad (\text{dB})
\]

or

\[
n - n_{\text{last}} \geq \text{Tx\_Power\_Report\_Interval}
\]

where

\[
M(n) = L + NI + \text{Offset\_SS}_{\text{perSS}} + \text{Offset\_BS}_{\text{perSS}} \quad (\text{dB})
\]

\[
M_{\text{avg}}(n) = 10 \log_{10} \left( \alpha_{p_{\text{avg}}} \cdot 10^{M(n)/10} + (1 - \alpha_{p_{\text{avg}}} ) \cdot 10^{(M_{\text{avg}}(n-1)/10)} \right)
\]

\[
n_{\text{last}} \quad \text{is the time index when the last SS Tx power report is sent. The unit is frame.}
\]

\[
\text{Tx\_Power\_Report\_Threshold}, \text{Tx\_Power\_Report\_Interval}, \text{and} \ \alpha_{p_{\text{avg}}} \text{are indicated in UCD. In}
\]

UCD, there are sets of those parameters sets: depending on the allocation CQICH to SS, the corre-

sponding parameter set shall be used.

With closed loop power control, the MS may not be able to implement the first trigger with
\text{Tx\_Power\_Report\_Threshold} in Equation (136) because several of the terms (\text{Offset\_SS}_{\text{perSS}},

\text{Offset\_BS}_{\text{perSS}}) are only defined in open loop power control. The MS can use the first trigger in Equation

(136) but set \text{Offset\_SS}_{\text{perSS}} to zero and \text{Offset\_BS}_{\text{perSS}} to the cumulative value of all power corrections

from the BS. Optionally, the MS can elect to ignore the first trigger and report transmission power status

only using the second trigger with \text{Tx\_Power\_Report\_Interval}.

The MS may stop reporting transmission power status in the following cases in order to lower ranging

channel loading and improve battery life:

\begin{itemize}
  \item The MS enters sleep mode (i.e., activates a PSC),
  \item The MS enters idle mode, or
  \item The MS has no remaining UL data to send.
\end{itemize}

If the MS stops reporting transmission power status, it should start sending transmission power status

immediately if UL allocations start (e.g., in case of new active UGS or ertPS connection) or if the MS sends

a BW Request Header requesting an UL allocation.

The MS should estimate the \( M_{\text{avg}}(n) \) on an ongoing basis, using all frames during availability periods

instead of only during frames when the MS report its transmission power

\subsection{8.4.10.3.2.2 Power control in handoff}

During handover, the target BS may provide BW allocation information to the MS using Fast\_Ranging\_IE
to send an RNG-REQ message. In case of FBSS handover, the target BS may allocate a CQICH for the MS
to report CINR, or the MS may transmit the bandwidth request ranging code in order to request uplink band-
width allocation at the target BS. In these cases, the target BS shall also transmit the

UL\_noise\_and\_interference\_level\_IE in the same frame in which the OFDMA_Fast\_Ranging\_IE or CQICH

Allocation\_IE is transmitted. This UL\_noise\_and\_interference\_level\_IE shall include at least the NI field

that corresponds to the same zone that Fast\_Ranging\_IE points to (i.e., the UL zone in which the MS may

transmit RNG-REQ) if the Fast\_Ranging\_IE is used. The UL\_noise\_and\_interference\_level\_IE shall

include at least the NI field that corresponds to the CQICH region if CQICH\_Allocation\_IE is transmitted.

Also, during the FBSS process, the target BS shall provide the UL\_noise\_and\_interference\_level\_IE that
includes at least the NI field corresponding to the Periodic Ranging Region if the BS does not allocate
CQICH to the MS. This NI value is used for the MS to determine the initial transmit power level for the transmission of bandwidth request ranging code to the target BS. In turn, the MS shall calculate the initial transmit power at the target BS as follows:

1) If the MS is in open loop power control mode with serving BS, then Equation (132) of 8.4.10.3.2 shall be used. In this calculation, the MS shall reuse Offset_BSperSS from its serving BS, while all other equation parameters shall be target BS related.

2) If the MS is in closed loop power control mode with serving BS, then Equation (137) shall be used:

\[
P_{TBS} = P_{last,SBS} - \text{RSSI}_{TBS} + \text{RSSI}_{last,SBS} + N_I_{TBS} - N_I_{last,SBS} + C/N_{TBS} - C/N_{last,SBS} + BS\_EIRP_{TBS} - BS\_EIRP_{SBS} - 10\log_{10}(R_{TBS}) + 10\log_{10}(R_{last,SBS})
\]

where

- \(P_{last,SBS}\): MS transmit power level of the last transmission to the SBS [dBm].
- \(P_{TBS}\): Initial MS transmit power level (dBm) to be used in subsequent HO-ranging, bandwidth request ranging, CQICH transmission or Fast_Ranging_IE allocation transmissions to the TBS.
- \(\text{RSSI}_{last,SBS}\): DL RSSI at MS of the SBS preamble, used to derive Tx power of last transmission at the SBS [dBm].
- \(\text{RSSI}_{TBS}\): DL RSSI of the TBS preamble, measured by the MS [dBm].
- \(N_I_{last,SBS}\): Combined noise+interference known at time of last transmission at the SBS [dBm].
- \(N_I_{TBS}\): Combined noise+interference at the TBS [dBm].
- \(C/N_{last,SBS}\): Carrier-to-noise level for assigned ULMCS of last transmission at the SBS [dB].
- \(C/N_{TBS}\): Carrier-to-noise level for ULMCS derived from the UIUC assigned to the Fast_Ranging_IE allocation, carrier-to-noise level for CDMA code, or carrier-to-noise level for FAST_FEEDBACK at the TBS [dB].
- BS\_EIRP_{SBS}: SBS equivalent isotropic transmit power (from DCD) [dBm].
- BS\_EIRP_{TBS}: TBS equivalent isotropic transmit power (from DCD settings in MOB_NBR-ADV) [dBm].
- \(R_{last,SBS}\): Repetition factor of assigned ULMCS of last transmission at the SBS.
- \(R_{TBS}\): Repetition factor of assigned ULMCS at the TBS.

3) If the MS does not have one of the parameters needed for the above calculations (open loop or closed loop), it shall disregard Fast_Ranging_IE allocations or CQICH_Allocation_IE allocations and perform CDMA handover ranging with the target BS.

During HO ranging following the first transmission of the first CDMA code until the completion of the ranging process, the power control mode to be used should be up to the MS. Upon completion of HO, the MS should use the power control mode it was in before the HO.

8.4.11 Fast-feedback channels

Fast-feedback slots may be individually allocated to SS for transmission of PHY-related information that requires fast response from the SS. The allocations are done in unicast manner through the fast-feedback MAC subheader (see 6.3.2.2.6), CQICH Control IE (see 6.3.2.3.38.5), or CQICH Allocation IE (see 8.4.5.4.11); and the transmission takes place in a specific UL region designated by UIUC = 0.

In addition, the fast feedback region may also contain MAP NACK channels and MAP ACK channels. Both MAP NACK and MAP ACK channels are assigned to the MS using the Persistent HARQ DL MAP IE (8.4.5.3.29) and the Persistent HARQ UL MAP IE (8.4.5.4.28).

Each fast-feedback slot consists of one OFDMA slot mapped in a manner similar to the mapping of normal UL data. A fast-feedback slot uses QPSK modulation on the 48 data subcarriers it contains and can carry a
data payload of 4 bits. Table 516 defines the mapping between the payload bit sequences and the subcarriers modulation.

The fast-feedback code words used in Table 516 belong to a set of orthogonal vectors and are mapped directly to the data subcarriers of a tile in frequency-first order starting from the first OFDMA symbol, and the tile indices are defined in Equation (65) for PUSC and Equation (68) for optional PUSC. The vectors are defined in Table 517.

</table>
where

\[ P_0 = \exp\left(j \cdot \frac{\pi}{4}\right) \]

\[ P_1 = \exp\left(j \cdot \frac{3\pi}{4}\right) \]

\[ P_2 = \exp\left(-j \cdot \frac{3\pi}{4}\right) \]

\[ P_3 = \exp\left(-j \cdot \frac{\pi}{4}\right) \]  

The fast-feedback slot includes 4 bits of payload data, whose encoding depended on the instruction given in the FFSH, CQICH Control IE, and CQICH Allocation IE. These encodings are defined in 8.4.11.1 through 8.4.11.15.

In order to maintain operation of link adaptation mechanisms at the BS and adequate CINR reporting, the MS should not transmit non-CINR report codewords (such as: the indication flag and the Extended rtPS bandwidth request codewords) on two consecutive CQICH allocations each in different frame that are allocated to it.

If MIMO feedback opportunities are allocated to the MS, then the MS should not transmit the non-CINR, and non-MIMO reports on three consecutive allocations each in different frame.

### 8.4.11.1 Fast DL measurement feedback

MIMO-capable MS shall measure post-processing CINR for each individual layers as shown in Figure 295. When the FFSH's Feedback Type field is 00, the MS shall report the post-processing average CINR (Avg CINR). When BS requests MS feedback through CQICH_Alloc_IE() or CQICH_Enhanced_Alloc_IE() with feedback_type field = 00, MS shall report Avg CINR as described next.
For a single layer MIMO system (Matrix A and Matrix B) denote \( p \) as the index for a pair of pilots, \( \sigma_p^2 \) is the average noise plus interference variance over MS's receive antennas and pair of pilots. Further denote \( C(d, y|H) \) as the receiver-constrained mutual information conditioned on the channel knowledge, wherein \( d \) is the transmitted signal, \( y \) is the post-processing receive signal and \( H \) is the channel matrix between Tx and Rx antennas.

For Matrix B the average CINR is given by Equation (139).

\[
\text{Avg\_CINR}_{dB} = 10 \log_{10} \left( e^{C(d, y|H)} - 1 \right)
\]

\[
C(d, y|H) = \frac{1}{P} \sum_{p=1}^{P} C_p(d_p, y_p|H_p)
\]

\[
C_p(d_p, y_p|H_p) = \frac{1}{N} \log \det \left( I_N + \frac{H_p H_p^H}{\sigma_p^2} \right)
\]

where \( N \) is the number of streams, i.e., \( N = 2 \) is this case.

For Matrix A the average CINR is given by Equation (140).

\[
\text{Avg\_CINR}_{dB} = 10 \log_{10} \left( e^{C(d, y|H)} - 1 \right)
\]

\[
C(d, y|H) = \frac{1}{P} \sum_{p=1}^{P} C_p(d_p, y_p|H_p)
\]

\[
C_p(d_p, y_p|H_p) = \log \left( 1 + \frac{1}{\sigma_p^2} \| H_p \|^2_F \right)
\]

where \( \| \cdot \|^2_F \) denotes the Frobenius norm of a matrix.

Standard-compliant approximations of Equation (139) and Equation (140) are shown next.

Referring to Figure 296, the following are defined:
$l$ is the index of an OFDMA symbol, $1 \leq l \leq L$

$j$ is the index of a “column”, and has resolution of two OFDMA symbols, $1 \leq j \leq J$

subcarrier block is a set of physically adjacent subcarriers,

$m$ is the index of subcarrier block, $1 \leq m \leq M$

$k$ is the index of a pair of pilots within one subcarrier block within one column, $1 \leq k \leq K$

$\Delta$ is a subset of the columns in the zone, $\Delta \subseteq \{1, 2, \ldots, J\}$

$|\Delta|$ is the cardinality of $\Delta$, where $2 \leq |\Delta| \leq J$

$\Lambda$ is a subset of the OFDMA symbols in the zone, $\Lambda \subseteq \{1, 2, \ldots, J\}$

$|\Lambda|$ is the cardinality of $\Lambda$, where $2 \leq |\Lambda| \leq J$

Note that the number of subcarrier blocks is implementation-dependent with the only constraint that $M \geq 1$. Also note that when working in segmented PUSC, only the active pilots in the subcarrier block should be considered.

The average CINR over a zone can be given by:

$$\text{Avg}_{\text{CINR}}_{\text{dB}} = 10\log_{10}(e^{\frac{C_{(d,y)[f]}}{q}} - q)$$

where $q = 0$ or $q = 1$ depending on the MS specific implementation. This is to say that MS specific implementation can drop the “1” inside the log term.

The capacity can be averaged over a zone as follows:
For Matrix B, we have

\[ C_{m,j} = \frac{1}{K} \sum_{k=1}^{K} \log \det \left( zI + \frac{H_{m,j,k}^H H_{m,j,k}}{\sigma_m^2} \right) \]

For Matrix A, we have

\[ C_{m,j} = \frac{1}{K} \sum_{k=1}^{K} \log \left( z + \frac{\|H_{m,j,k}\|^2}{\sigma_m^2} \right) \]

where \( z = 0 \) or \( z = 1 \) depending on the MS specific implementation. This is to say that the MS specific implementation can drop the “\( I \)” inside the determinant for the capacity expression for Matrix B and the “1” inside the log term for the capacity expression for Matrix A.

The noise can be averaged over the \( m \)-th subcarrier block as follows:

\[ \sigma_m^2 = \frac{1}{K} \sum_{k=1}^{K} \sum_{\lambda_k=1} \sigma_{\lambda_k}^2 \]

where \( \sigma_{\lambda_k}^2 \) is the noise plus interference variance averaged over the MS’s receive antennas on a single pilot position \((\lambda_k)\).

When the Feedback_type field in CQICH_Enhanced_Alloc_IE() is 0b000 with CQICH type 0b101, Equation (141) shall be used.

\[ \text{Payload bits nibble} = \begin{cases} 0, & S/N \leq 1 - B \\ n, & (2n - 1 - B) < S/N \leq (2n + 1 - B), \quad 0 < n < 15 \\ 15, & S/N > 29 - B \end{cases} \quad (141) \]

where \( B \) is the positive integer value indicated in the SN Reporting Base TLV (see 11.7.22). \( B \) shall default to “3” if the SN Reporting Base TLV was not included in the REG-RSP.

For an MS that supports the feedback method by using feedback header, if \( M \) is the value of the indication flag in UCD, the MS shall set the payload bits nibble as \( M - 1 \). It should not use the payload bits nibble calculated based on Equation (141).

For band AMC operation, the SS shall report differential of CINR of selected bands on its fast-feedback channel or feedback header type 1101.

When the CINR report is requested on an STC zone (CQICH Alloc IE with “Feedback type”=’0b00’ or ‘0b01’, “Report type”=’1’ and “Zone type”=’01’) the method for calculating the CINR depends on the MIMO mode. The MS shall calculate the CINR in accordance with the MIMO mode of its most recent unicast burst.
(i.e., with explicit CID or RCID in the MAP) in the STC zone of interest regardless of the frame it appeared in, and without consideration of whether the burst was decoded successfully (using the start of a burst as its reference point, the last burst in a zone is the one with the highest sub-channel offset among those bursts that have the highest symbol offset.) If there has not been any unicast burst (i.e., with explicit CID or RCID in the MAP) transmitted in the STC zone to the MS in any frame since the last initial network entry or re-entry (after handover or idle mode), the MS shall prepare the CINR report according to the MIMO mode of the STC zone.

For SS with more than one receive antennas, the reported CINR shall include the processing gain associated with the multiple antennas and use the quantization defined for the CQICH.

8.4.11.2 Fast MIMO feedback

When the FFSH’s Feedback Type field is 01 or 10 the SS shall report the MIMO coefficient the BS should use for best DL reception (see 8.4.8.1.6). The mapping for the complex weights is shown in Figure 297.

![Figure 297—Mapping of MIMO coefficients to fast MIMO feedback payload bits](image)

When CQI Feedback Type field in CQICH_Enhanced_Alloc_IE() (see 8.4.5.4.14) is 0b011 and CQICH type is 0b101, the MS shall report the MIMO coefficient the BS should use for best DL reception. The mapping for the complex weights is shown in Figure 297. For this type of feedback, if $N$ is the number of BS Tx antennas, then $(N - 1)$ CQICH shall be allocated to the MS, and MS shall report the desired antenna weights of antenna 1 through $N - 1$ based on antenna 0.
8.4.11.3 Mode selection feedback

For an SS that supports the STC option (see 8.4.8), when the FFSH’s Feedback Type field is 11 or at a specific frame indicated in the CQICH_Alloc_IE(), the SS shall send its selection in terms of MIMO mode (STTD versus SM) or permutation mode on the assigned fast-feedback channel. Table 518 shows the encoding of payload bits for the fast-feedback slot (see 8.4.5.4.9), and Table 519 shows the encoding of payload bits for the secondary fast-feedback slot.

8.4.11.4 Effective CINR feedback for fast-feedback channel

When the feedback type field in the CQICH_IE() is 0b01 or the effective CINR report is request by REP-REQ, the SS shall report the effective CINR, as defined in 6.3.18, according to Table 520. To avoid ambiguity, both the BS and the SS must know the FEC type assumed for this report. The FEC type assumed for the MCS column is the first FEC type in the table in 11.8.3.5.2 for which the SS and BS have successfully negotiated the capability exchange. If none of the FEC types in 11.8.3.5.2 have been successfully negotiated, then the mandatory FEC type shall be assumed. In the case of 6-bit CQI, Table 520 shall be applied to the 4 LSB bits and the two MSB bits shall be set to ‘00’.

8.4.11.5 Enhanced fast-feedback channels

Enhanced fast-feedback slots may be individually allocated to an MS for transmission of PHY related information that requires fast response from the MS. The allocations are performed using one of the following options:

- In a unicast manner through the FFSH (see 6.3.2.2.6)
- The CQICH_Control_IE() (see 6.3.2.3.38.5)
- The CQICH_Alloc_IE() (see 8.4.5.4.11)
- The CQICH_Enhanced_Alloc_IE() (see 8.4.5.4.14)
- The MIMO_Compact_DL-MAP_IE() (see 6.3.2.3.38.6.7)
- Dedicated_MIMO_DL_Control_IE() (8.4.5.3.21.1)
- The AAS_SDMA_DL_IE() (8.4.5.4.24)

The transmission takes place in a specific UL region designated by UIUC = 0.

Each 3-bit MIMO fast-feedback slot consists of 1/2 OFDMA slots mapped in a manner similar to the mapping of ACK Channel. An enhanced fast-feedback slot uses QPSK modulation on the 24 data subcarriers it contains, and can carry a data payload of 3 bits. Table 521 defines the mapping between the payload bit sequences and the subcarriers modulation.

Table 522 defines the mapping between the payload bit sequences and the subcarriers modulation for 6 bit CQI type 0b000 and 0b100. For CQICH types 0b110, 0b111, and 0b001 the 6 bits CQI shall follow the mapping as described below:

- CQICH type 0b110 (even): Tile(0), Tile(2), Tile(4)
- CQICH type 0b111 (odd): Tile(1), Tile(3), Tile(5)
- CQICH type 0b001 (18 bit mapping in a full slot):
  - Bit17 – Bit12 – Tile (0), tile (3)
  - Bit11 – Bit6 – Tile (1), tile (4)
  - Bit5 – Bit0 – Tile (2), tile (5)

The fast-feedback channel is orthogonally modulated with QPSK symbols. Let $M_{n,8m+k}(0 \leq k \leq 7)$ be the modulation symbol index of the $k$-th modulation symbol in the $m$-th UL tile of the $n$-th fast-feedback channel. The possible modulation patterns composed of $M_{n,8m} , M_{n,8m+1} , \ldots , M_{n,8m+7}$ the $m$-th tile of the $n$-th fast-feedback channel are defined in Table 523.

Table 523—Orthogonal modulation index in fast-feedback channel

</table>

where

$$P0 = \exp \left( j \cdot \frac{2\pi}{4} \right)$$

$$P1 = \exp \left( j \cdot \frac{3\pi}{4} \right)$$
$P_2 = \exp\left(-j \cdot \frac{3\pi}{4}\right)$

$P_3 = \exp\left(-j \cdot \frac{\pi}{4}\right)$

$M_{n,8m+i}$ is mapped to a fast-feedback channel tile, as shown in Figure 298, for PUSC UL subchannel, and in Figure 299, for optional PUSC UL subchannel. A fast-feedback channel is mapped to one subchannel composed of six tiles.

The enhanced fast-feedback slot includes 6 bits of payload data, whose encoding depends on the instruction given in the FFSH, the CQICH_Control_IE(), the CQICH_Alloc_IE(), or the CQICH_Enhanced_Alloc_IE(). The following subclauses define these encodings.

### 8.4.11.6 Fast DL measurement feedback for enhanced fast-feedback channel

When the FFSH’s Feedback Type field is 0b00 or the feedback is requested through CQICH_Alloc_IE() (see 8.4.5.4.11), or the Feedback Type field in CQICH_Enhanced_Alloc_IE() is 0b000-0b010 with CQICH type 0b000 or 0b100 (see 8.4.5.4.13), the MS shall report the SNR it measures on the DL. Equation (142) shall be used.

\[
P_2 = \exp\left(-j \cdot \frac{3\pi}{4}\right)
\]

\[
P_3 = \exp\left(-j \cdot \frac{\pi}{4}\right)
\]
where $B$ is the positive integer value indicated in the SN Reporting Base TLV (see 11.7.22). $B$ shall default to “3” if the SN Reporting Base TLV was not included in the REG-RSP.

For MIMO capable MSs, if the BS allocates a single CQICH to the MS in UL-MAP (CQICH_Num = 0) for the purposes of Fast DL Measurement, the MS shall report the effective post processing SNR Avg CINR as defined in 8.4.11.1. Otherwise, if the BS allocate multiple CQICHs to the MS in UL-MAP (CQICH_Num > 0) for the purposes of Fast DL Measurement, the MS shall report post processing S/N of individual layers in order of layer indices.

### 8.4.11.7 Fast MIMO feedback of quantized precoding weight for enhanced fast-feedback channel

When the FFSH’s Feedback Type field is 0b01 or 0b10, or the CQI Type field in the MIMO Compact DL-MAP IE() (see 6.3.2.3.38.6.7) is 0b01, or the Feedback Type field in CQICH_Enhanced_Alloc_IE() (see 8.4.5.4.13) is 0b011 with CQICH type 0b000 or 0b100, the MS shall report the MIMO coefficient the BS should use for best DL reception. The mapping for the complex weights is shown in Figure 300. For this type of feedback, if $N$ is the number of BS Tx antennas, then $(N−1)$ CQICH shall be allocated to the SS and SS shall report the desired antenna weights of antenna 1 through $N−1$ based on antenna 0.

\[
\text{Payload bits} = \begin{cases} 
0, & S/N \leq -B \\
n, & (n - 1 - B) < (S/N) \leq (n - B), 0 < n < 31 \\
31, & S/N > 30 - B 
\end{cases}
\] (142)
When the enhanced fast-feedback channel is employed, the SS may report the MIMO mode feedback on the assigned CQICH when the FFSH’s Feedback Type field is 0b00; or the Feedback Type field in the MIMO Compact DL-MAP IE() (see 6.3.2.3.38.6.7) is 0b000, 0b001, or 0b010; or the Feedback Type field in CQICH_EHanced_Alloc_IE() (see 8.4.5.4.14) is 0b000, 0b001, or 0b010 with CQICH type 0b000 or 0b100. The encoding of payload bits is shown in Table 524.

</tr>
</tbody>
</table>

Also, the codeword numbered 39 (i.e., 0b100111) is used as an acknowledgement for the Anchor BS Switch IE.

8.4.11.10 UEP fast-feedback

When the UEP fast-feedback is employed and the FFSH’s Feedback Type field is 00 or the BS requests the feedback through CQICH_Alloc_IE() or CQICH_Control_IE(), the MS may report the feedback payload on the assigned CQICH by using the following UEP fast-feedback method. The UEP fast-feedback provides the payload bits carried by the fast-feedback channel with the unequal error protection (UEP) capability. The UEP fast-feedback repeats each payload bit according to a predefined repetition ratio, as illustrated in Figure 301. The repeated bit sequence is interleaved and used for binary DPSK modulation on the subcarriers for the fast-feedback channel.

When the 4-by-3 UL tile structure is used (see 8.4.6.2.1), the number of tiles in a channel, \( N \), is 6 and the number of subcarriers in a tile, \( L \), is 12. When the 3-by-3 UL tile structure is used (see 8.4.6.4.1), \( N = 6 \) and \( L = 9 \).

When the MS reports the measured S/N, each payload bit is repeated according to the predefined UEP ratio \( R_0:R_1:R_2:R_3 \), where \( R_0, R_1, R_2, \) and \( R_3 \) represent the repetition number for the first payload bit \( b_0 \) (MSB), the...
second payload bit \( b_1 \), the third payload bit \( b_2 \), and the fourth payload bit \( b_3 \) (LSB), respectively. In case of the 4-bit CQI payload, a ratio of \( R_0:R_1:R_2:R_3 = 26:19:14:7 \) is used for the 4-by-3 UL tile structure, and \( R_0:R_1:R_2:R_3 = 19:14:10:5 \) is used for the 3-by-3 UL tile structure.

The repeated bit sequence is interleaved according to Equation (143) before binary DPSK modulation.

\[
y = ((xR)/N)\mod(R) + \left\lfloor x/N \right\rfloor
\]

where

- \( y \) denotes the bit index in the interleaved bit sequence (\( y = 0, 1, 2, c, R-1 \))
- \( x \) denotes bit index in the repeated bit sequence (\( x = 0, 1, 2, c, R-1 \))

The length of the repeated bit sequence is \( R = R_0 + R_1 + R_2 + R_3 = N(L-1) = 66 \) for the 4-bit CQI. The interleaved bit sequence is divided into \( N \) groups and each group has \( L-1 \) bits. The \( n \)-th group (\( n = 0, 1, \ldots, cN-1 \)) is used for binary DPSK modulation on the subcarriers in the \( n \)-th UL tile, as shown in Figure 301. The first subcarrier in each tile is used as a phase reference. The \( L-1 \) bits in the \( n \)-th group are mapped to \( L \) DPSK symbols for the \( n \)-th tile as shown in Equation (144).

\[
C_{n,k}^{\text{CQI}} = \begin{cases} 
1 & (k = 0) \\
C_{n,k-1}^{\text{CQI}} & k > 0 \text{ and } (B_{n,k-1}^{\text{CQI}} = 0) \\
-C_{n,k-1}^{\text{CQI}} & k > 0 \text{ and } (B_{n,k-1}^{\text{CQI}} = 1)
\end{cases}
\]

where

- \( C_{n,k}^{\text{CQI}} \) is the mapping symbol of the \( k \)-th subcarrier of the \( n \)-th tile (\( k = 0, 1, \ldots, L-1 \))
- \( B_{n,k}^{\text{CQI}} \) is the \( k \)-th bit of \( n \)-th group in the interleaved bit sequence (\( k = 0, 1, \ldots, L-2 \))
8.4.11.11 Band AMC differential CINR feedback for enhanced fast-feedback channel

When the band AMC operation is triggered, the MS shall report the differential of CINR for $N$ selected bands (increment: 1 and decrement: 0 with a step of 1 dB) on its enhanced, primary fast-feedback channel or secondary fast-feedback channel. The first $2^N$ codewords are used. The differential reporting shall be in the order of the band indices with the LSB of the codeword referencing the band with the lowest index.

8.4.11.12 Indication flag feedback

For an MS that supports the feedback method using the feedback header, the MS can send an indication flag on the fast-feedback channel, the enhanced fast-feedback channel, or the primary/secondary fast-feedback channel. The indication flag is a specific encoding of the payload bits on the fast-feedback channel or the enhanced fast-feedback channel. The indication flag is used by the MS to indicate to the BS its intention to transmit a feedback header or a BR header without the need to perform BR ranging. After receiving the indication flag from the MS, the BS may allocate the required UL resource to the MS.
In order to maintain operation of link adaptation mechanisms at the BS and adequate CINR reporting, the MS shall not transmit the indication flag codeword on two consecutive CQICH allocations that are allocated to it.

For the case of fast-feedback channel or secondary fast-feedback changeful the Indication Flag feedback operation is enabled, the specific encoding of the payload bits is defined in the Use CQICH indication flag TLV. This specific encoding is reserved for the purpose of indication flag and shall not be used to send other feedback information (see 8.4.11.1).

For the case of enhanced fast-feedback channel or primary fast-feedback channel, the encoding of 0b111100 shall be used as the indication flag (see Table 524).

### 8.4.11.13 Primary and secondary fast-feedback channels

A primary fast-feedback slot consists of 1 OFDMA slots mapped in a manner similar to the mapping of normal UL data. A primary fast-feedback slot uses QPSK modulation on the 48 data subcarriers of UL PUSC tiles it contains, and can carry a data payload of 6 bits. The primary fast-feedback slot has identical mapping between the payload bit sequences and the subcarriers modulation as the enhanced fast-feedback 6-bit payload slot except null pilot subcarriers within the slot. (See Figure 302).

A secondary fast-feedback slot consists of one OFDMA slot mapped in a manner similar to the mapping of normal UL data. A secondary fast-feedback slot uses QPSK modulation on the 24 pilot subcarriers of UL PUSC tiles it contains, and can carry a data payload of 4 bits. Table 529 defines the mapping between the payload bit sequences and the subcarriers modulation.

#### Table 529—Secondary fast-feedback channel subcarrier modulation with 4 bit

<table>
<thead>
<tr>

<td>1,1,1,0,0</td>
<td>1001</td>
<td>1,3,2,2,3,1</td>
</tr>
</tbody>
</table>
The secondary fast-feedback channel is orthogonally modulated with QPSK symbols. Let $M_{n,4m+k}$ ($0 \leq k \leq 3$) be the modulation symbol index of the $k$-th modulation symbol in the $m$-th UL PUSC tile of the $n$-th secondary fast-feedback channel. The possible modulation patterns composed of $M_{n,4m+k}$ in the $m$-th tile of the $n$-th secondary fast-feedback channel are defined in Table 530.

### Table 530—Orthogonal modulation index in secondary fast-feedback channel

<table>
<thead>

<td>P0, P1, P2, P3</td>
</tr>
<tr>
<td>3</td>
<td>P1, P0, P3, P2</td>
</tr>
</tbody>
</table>

where

$P_0 = \exp\left(\frac{j\pi}{4}\right)$

$P_1 = \exp\left(\frac{j3\pi}{4}\right)$

$P_2 = \exp\left(-\frac{j3\pi}{4}\right)$

$P_3 = \exp\left(-\frac{j\pi}{4}\right)$

$M_{n,4m+k}$ are mapped to secondary fast-feedback channel tile as shown in Figure 303 for PUSC UL subchannel. A secondary fast-feedback channel is mapped to one subchannel composed of six tiles.
8.4.11.14 Extended rtPS BR

If an MS has Extended rtPS connections, the MS may inform the serving BS of the existence of pending erTPS data. The codeword 0b111011 is used for that purpose. If the BS receives the codeword (i.e. 0b111011) on CQICH from the MS, the BS should allocate for the MS an UL burst corresponding to the largest Maximum Sustained Traffic Rate of the MS's stopped erTPS UL service flows. The connection for which the MS uses the UL allocation implicitly indicates the erTPS service flow to resume. The MS may alternatively include the erTPS resumption bitmap extended subheader (6.3.2.2.7.9) to indicate the erTPS service flows to resume.

8.4.11.15 MIMO feedback for Tx beamforming

Codebooks are defined for the feedback of MIMO Tx beamforming, whose codeword may be employed as the beamforming matrix in MIMO precoding in 8.4.8.3.6. The vector codebooks for 2x1, 3x1, and 4x1 with 3-bit feedback index are listed in Table 531, Table 532, and Table 533. The notation $V(N_t, S, L)$ denotes the vector codebook, which consists of $2^L$ complex, unit vectors of a dimension $N_t$, and $S$ denotes the number of streams. The integer $L$ is the number of bits required for the index that can indicate any vector in the codebook.

Table 531—$V(2,1,3)$

<td>-0.8779 - j0.3481</td>
<td></td>
</tr>
</tbody>
</table>
The codebooks in Table 531, Table 532, and Table 533 are produced by generating expressions one per table. These tables are optimized for generation efficiency and storage memory.

Three operations are employed and they employ floating point arithmetic in IEEE Std 754, whose final results are rounded to four decimal places. The first operation generates a unitary \( N \times N \) matrix \( H(v) \) using an \( N \) vector \( v \) as shown in Equation (145).

\[
H(v) = \begin{cases} 
I, & v = e_1 \\
I - pww^H, & \text{otherwise} 
\end{cases} 
\]  

(145)

where

\[ w = v - e_1 \text{ and } e_1 = [1 \ 0 \ ... \ 0] \]

\[ p = \frac{2}{\|w\|^2} \]

\( I \) is the \( N \times N \) identity matrix

\( ()^H \) denotes the conjugate transpose operation

Two vector codebooks \( V(3,1,6) \) and \( V(4,1,6) \) are generated as follows. All the vector codewords \( v_i, i = 2, \ldots, 2^L \) are derived from the first codeword \( v_1 \) as follows:

\[
\tilde{v}_i = H(s)Q^{i-1}(u)H^H(s) \cdot v_1, \text{ for } i = 2, \ldots, 2^L,
\]
\[ v_i = \tilde{v}_i e^{j\phi_i}, \text{ for } i = 2, \ldots, 2^L, \]

where

\[
Q'(u) = \text{diag} \left( e^{j\frac{2\pi}{N} u_1}, \ldots, e^{j\frac{2\pi}{N} u_N} \right)
\]

is a diagonal matrix

\[ u = u = [u_1 \ldots u_N] \]

is an integer vector

\[
v_1 = \frac{1}{\sqrt{N}} \begin{bmatrix} 1 & e^{j\frac{2\pi}{N}} & \ldots & e^{j\frac{2\pi}{N} (N-1)} \end{bmatrix}^T
\]

\[ \phi_i \]

is the phase of the first entry of \( \tilde{v}_i \)

The parameters for the generation of \( V(3,1,6) \) and \( V(4,1,6) \) are listed in Table 534.

<td>[1.3954– j0.0738, 0.0206+ j0.4326, -0.1658– j0.5445, 0.5487– j0.1599]^T</td>
</tr>
</tbody>
</table>

The second operation generates an \( N \) by \( M+1 \) unitary matrix from a unit \( N \) vector and a unitary \( N-1 \) by \( M \) matrix as shown in Equation (146):

\[
HC(v_N, A_{(N-1)M}) = H(v_N) \begin{bmatrix} 1 & 0 & \ldots & 0 \\ 0 & \ddots & & \vdots \\ 0 & \ldots & 0 & A_{(N-1)M} \end{bmatrix}
\]

where

\[ N-1 \geq M; \] the \( N-1 \) by \( M \) unitary matrix has property \( A^H A = I \).

The third operation generates an \( N \) by \( M \) matrix from a unit \( N \) vector, \( v_N \), by taking the last \( M \) columns of \( H(v_N) \) as shown in Equation (147).

\[
HE(v_N, M) = H(v_N)[N-M+1:N]
\]

The fourth operation generates an \( N \) by 2 matrix from a unit \( N \) vector, \( v_N \), by taking the first 2 columns of \( H(v_N) \) as shown in Equation (148).

\[
HF(v_N) = H(v_N)_{1:2}
\]

The four operations jointly generate eleven matrix codebooks from vector codebooks as shown in Table 535, where each entry is the generating operation of one codebook.
Table 535 contains operations to generate codebooks $V(N_t, S, L)$ for $N_t = 2, 3, 4$, $S = 2, 3, 4$, and $L = 3$ and 6.

**Table 535—Operations to generate codebooks**

<td>$H(V(4,1,6))$</td>
</tr>
</tbody>
</table>

The set notation $V(N_t, 1, L)$ in the input arguments of the operations denotes that each vector in the codebook $V(N_t, 1, L)$ is sequentially taken as an input to the operations. The output of the operation with one or more codebooks as input arguments is also a codebook. For example, in $HC(V(3,1,3), H(V(2,1,3)))$ has two codebooks as input. The first is $V(3,1,3)$ with 8 vectors and the second is $H(V(2,1,3))$ with 8 2x2 matrices, which are computed from $V(2,1,3)$. The feedback index is constructed by sequentially concatenating all the indexes of the input argument vector codebooks in binary format. For example, the feedback index of $HC(V(3,1,3), H(V(2,1,3)))$ is constructed as $i_2j_2$, where $i_2$ and $j_2$ are the indexes of the vectors in codebooks $V(3,1,3)$ and $V(2,1,3)$ in binary format respectively.

Table 536, Table 537, Table 538, and Table 539 are included to illustrate codebooks generated using the rules defined above.

8.4.11.16 MAP ACK Channel

Each MAP ACK channel occupies one fast feedback slot. The MAP ACK channel shall be individually assigned to the MS for transmitting an acknowledgement of the receipt of the respective Persistent HARQ DL MAP IE (8.4.5.3.29), the Persistent HARQ UL MAP IE (8.4.5.4.28) or H-FDD group switch instructions (8.4.4.2.1). The transmission takes place in a specific UL region designated by the UIUC=0.

Each MAP ACK channel shall consist of 1 OFDMA slot mapped in a manner similar to UL data. A MAP ACK channel slot uses QPSK modulation on the 48 data subcarriers it contains and carries a data payload of 1 bit. Table 540 defines the mapping between the payload bit sequence and the subcarriers modulation.

8.4.12 Channel quality measurements

8.4.12.1 Introduction

RSSI and CINR signal quality measurements and associated statistics can aid in such processes as BS selection/assignment and burst adaptive profile selection. As channel behavior is time-variant, both mean and standard deviation are defined. Implementation of the RSSI and CINR statistics and their reports is mandatory.

The process by which RSSI measurements are taken does not necessarily require receiver demodulation lock; for this reason, RSSI measurements offer reasonably reliable channel strength assessments even at low signal levels. On the other hand, although CINR measurements require receiver lock, they provide information on the actual operating condition of the receiver, including interference and noise levels, and signal strength.

8.4.12.2 RSSI mean and standard deviation

When collection of RSSI measurements is mandated by the BS, an SS shall obtain an RSSI measurement (implementation-specific). From a succession of RSSI measurements, the SS shall derive and update estimates of the mean and the standard deviation of the RSSI, and report them via REP-RSP messages.

Mean and standard deviation statistics shall be reported in units of dBm and dB, respectively. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from –40 dBm (encoded 0x53) to –123 dBm (encoded 0x00). Values outside this range shall be assigned the closest extreme value within the scale.

The method used to estimate the RSSI of a single message is left to individual implementation, but the relative accuracy of a single signal strength measurement, taken from a single message, shall be ± 2 dB, with an absolute accuracy of ± 4 dB. This shall be the case over the entire range of input RSSIs. In addition, the range over which these single-message measurements are measured should extend 3 dB on each side beyond the –40 dBm to –123 dBm limits for the final averaged statistics that are reported.

One possible method to estimate the RSSI of a signal of interest at the antenna connector is given by Equation (149).

\[
RSSI = 10 \left( \frac{\frac{G_{rt}}{10} \times 1.2567 \times 10^4 V_c^2}{(2^{2B})R} \right) \left( \frac{1}{N-1} \sum_{n=0}^{N-1} |Y_{IorQ}(k,n)| \right)^2 \text{mW}
\]

where

- \(B\) is ADC precision, number of bits of ADC
- \(R\) is ADC input resistance (\(\Omega\))
- \(V_c\) is ADC input clip level (V)
- \(G_{rt}\) is analog gain from antenna connector to ADC input
- \(Y_{IorQ}(k,n)\) is \(n\)-th sample at the ADC output of I or Q-branch within signal \(k\)
- \(N\) is number of samples

The (linear) mean RSSI statistics (in milliwatts), derived from a multiplicity of single messages, shall be updated using Equation (150).

\[
\delta[k] = \begin{cases} 
R[0] & k = 0 \\
(1 - \alpha_{avg}) \delta[k-1] + \alpha_{avg} R[k] & k > 0 
\end{cases} \text{mW}
\]
where

\[ k \] is the time index for the message (with the initial message being indexed by \( k = 0 \), the next message by \( k = 1 \), etc.)

\[ R[k] \] is the RSSI in mW measured during message \( k \), and \( \alpha_{\text{avg}} \) is an averaging parameter specified by the BS.

The mean estimate in dBm shall then be derived from Equation (151).

\[
\hat{\mu}_{RSSI \ dBm}[k] = 10 \log(\mu_{RSSI}[k]) \quad \text{dBm}
\]  

(151)

To solve for the standard deviation in dB, the expectation-squared statistic shall be updated using Equation (152),

\[
x_{RSSI}^2[k] = \begin{cases} 
[R(0)]^2 & k = 0 \\
(1 - \alpha_{\text{avg}})x_{RSSI}^2[k-1] + \alpha_{\text{avg}}[R[k]]^2 & k > 0 
\end{cases} \quad (\text{mW})^2
\]  

(152)

and the result applied to Equation (153).

\[
\hat{\sigma}_{RSSI \ dB} = 5 \log\left(\left|x_{RSSI}^2[k] - (\hat{\mu}_{RSSI}[k])^2\right|\right) \quad \text{dB}
\]  

(153)

The message time index is incremented every frame. The reported RSSI value shall be an estimate of the received signal strength of the frame preamble of the associated segment of the particular BS.

### 8.4.12.3 CINR mean and standard deviation

When physical CINR measurements are mandated by the BS, an SS shall obtain a CINR measurement (implementation-specific). From a succession of these measurements, the SS shall derive and update estimates of the mean and/or the standard deviation of the CINR and report them via REP-RSP messages and/or report the estimate of the mean of the physical CINR via the fast-feedback channel (CQICH).

For the REP-RSP, the following encoding shall be used unless different encoding scheme is defined. Mean and standard deviation statistics for CINR shall be reported in units of decibels. To prepare such reports, statistics shall be quantized in 1 dB increments, ranging from a minimum of −10 dB (encoded 0x00) to a maximum of 53 dB (encoded 0x3F). Values outside this range shall be assigned the closest extreme value within the scale.

The method used to estimate the CINR of a single message is left to individual implementation, but the relative and absolute accuracy of a CINR measurement derived from a single message shall be ±1 dB and ±2 dB, respectively. The specified accuracy shall apply to the range of CINR values starting from 3 dB below SNR of the most robust rate to 10 dB above the SNR of the least robust rate. See Table 545 in 8.4.14.1.1.

If a physical CINR report from the preamble was instructed, then the reported CINR shall be an estimate of the CINR over the subcarriers of the preamble. For the frequency reuse configuration = 3 type, the reported CINR shall be the estimate of the CINR over the modulated subcarriers of the preamble. For the frequency reuse configuration = 1, the reported CINR shall be the estimate of the average CINR over all subcarriers of the preamble except the guard subcarriers and the DC subcarriers. In other words, the signal on the unmodulated subcarriers (except the guard subcarriers and the DC subcarriers) shall also be considered as noise and interference for the CINR estimate of the frequency reuse configuration = 1. The reported value
shall represent the average CINR on nonboosted data subcarriers of the first zone in the frame; hence preamble boosting shall be compensated for in both desired signal and interference/noise calculation.

If a physical CINR measurement is made for the purpose of computing a scan or handover trigger (Table 577) the CINR metric for the serving BS and the neighbor BS shall be estimates of the physical CINR measured on the preambles. For the serving BS, the physical CINR shall be computed according to the reuse factor indicated in the MOB_NBR-ADV “Reuse factor for SBS CINR calculation for scan and handover” field (Table 144). For the neighbor BS the physical CINR shall be computed according to the reuse factor indicated in the MOB_NBR-ADV “Preamble Index/Subchannel Index” field (Table 144) for each advertised neighbor BS shall be the same as the “Reuse factor for SBS CINR calculation for scan and handover” indicated by that neighbor BS in its MOB_NBR-ADV. After the MS performs handover to a new serving BS, it shall compute physical CINR for scan and handover purposes using the reuse factor indicated in the MOB_NBR-ADV “Preamble Index/Subchannel Index” field advertised by the previous serving BS until it receives a MOB_NBR-ADV from the new serving BS.

In case a physical CINR report on a specific permutation zone was instructed, then the reported value shall represent the average CINR on nonboosted data subcarriers of the zone on which measurement was requested; hence pilot boosting shall be compensated for in both desired signal and interference/noise calculation.

In case a physical CINR report on an STC zone is instructed, the SS shall report the average post-combined CINR.

In addition, the range over which these single-packet measurements are measured should extend 3 dB on each side beyond the –10 dB to 53 dB limits for the final reported, averaged statistics.

One possible method to estimate the CINR of a single message is to compute the ratio of the sum of signal power and the sum of residual error for each data sample, using Equation (154).

$$\text{CINR}[k] = \frac{\sum_{n=0}^{N-1} |r[k, n]|^2}{\sum_{n=0}^{N-1} |r[k, n] - s[k, n]|^2}$$

(154)

where

- $r[k, n]$ is the received sample $n$ within message measured at time index $k$ in frame units
- $s[k, n]$ is the corresponding detected or pilot sample (with channel state weighting)

The message time index is incremented every frame. The SS shall maintain separate message time index counters and mean CINR estimates for REP-RSP-based reports and for fast-Feedback-based reports. When the CINR configuration is changed (i.e., CINR report configuration in a CQICH IE or REP-REQ message differs from the previous CQICH IE or REP-REQ, respectively), the SS shall reset the corresponding message time index to zero.

When the MS is required to measure CINR for handover, the mean CINR statistic (in dB) shall be derived from a multiplicity of single messages using Equation (155).

$$\hat{\mu}_{\text{CINR, db}}[k] = 10 \log_{10}(\hat{\mu}_{\text{CINR}}[k])$$

(155)

where
\( \hat{\mu}_{\text{CINR}}[k] = \begin{cases} 
\text{CINR}[0] & k = 0 \\
(1 - \alpha_{\text{avg}}) \hat{\mu}_{\text{CINR}}[k - 1] + \alpha_{\text{avg}} \text{CINR}[k] & k > 0 
\end{cases} \) (156)

\( \text{CINR}[k] \) is a linear measurement of CINR (derived by any mechanism that delivers the prescribed accuracy) for message \( k \)

\( \alpha_{\text{avg}} \) is an averaging parameter specified by the BS

For CINR report via CQICH, REP-RSP, and Feedback Header for link adaptation, the MS shall derive mean CINR (in dB) using Equation (157).

\[ \hat{\mu}_{\text{CINR \ dB}}[k] = 10 \log(\hat{\mu}_{\text{CINR}}[k]) \] (157)

where

\[ \hat{\mu}_{\text{CINR}}[k] = \begin{cases} 
\text{CINR}[0] & k = 0 \\
(1 - \alpha_{\text{avg}}) \hat{\mu}_{\text{CINR}}[k - 1] + (1 - \alpha_{\text{avg}}) \alpha_{\text{avg}} \text{CINR}[k] & k > 0 
\end{cases} \] (158)

\( \text{CINR}[k] \) is a linear measurement of CINR for the \( k \)-th measurement; and \( n \) is number of consecutive frames in which no measurement is made. In frames where no measurement is made, the MS shall report the latest averaged results.

To solve for the standard deviation, if logarithmic CINR calculation is not enabled (see 11.8.3.5.19), the expectation-squared statistic shall be updated using Equation (159).

\[ x_{\text{CINR}}^2[k] = \begin{cases} 
[\text{CINR}[0]]^2 & k = 0 \\
(1 - \alpha_{\text{avg}}) x_{\text{CINR}}^2[k - 1] + \alpha_{\text{avg}} \text{CINR}[k] & k > 0 
\end{cases} \] (159)

and the result applied to

\[ \hat{\sigma}_{\text{CINR \ dB}} = 5 \log \left[ (x_{\text{CINR}}^2[k] - (\hat{\mu}_{\text{CINR}}[k])^2) \right] \text{ dB} \] (160)

\( \text{CINR}[k] \) is a linear measurement of CINR for the \( k \)-th measurement; and \( n \) is number of consecutive frames in which no measurement is made. In frames where no measurement is made, the MS shall report the latest averaged results.

If logarithmic CINR standard deviation calculation is enabled (see 11.8.3.5.19), the MS shall calculate the standard deviation in decibel format using Equation (161) through Equation (163).

1) Compute the first moment of CINR using Equation (161) as:

\[ x_{\text{CINR \ dB}}^2[k] = \begin{cases} 
\text{CINR}_{\text{dB}}[0] & k = 0 \\
(1 - \alpha_{\text{avg}}) x_{\text{CINR \ dB}}^2[k - 1] + (1 - \alpha_{\text{avg}}) \alpha_{\text{avg}} \text{CINR}_{\text{dB}}[k] & k > 0 
\end{cases} \] (161)
where \( n \) is number of consecutive frames in which no measurement is made, and \( \text{CINR}_{db}[k] = 10 \log_{10}(\text{CINR}[k]) \).

2) Compute the second moment of CINR using Equation (162) as follows:

\[
x_{\text{CINR}, \text{db}}[k] = \begin{cases} (\text{CINR}_{db}[0])^2 & k = 0 \\ (1 - \alpha_{\text{avg}})^{x_{\text{CINR}, \text{db}}[k-1]} + (1 - (1 - \alpha_{\text{avg}})^{x_{\text{CINR}, \text{db}}[k-1]})(\text{CINR}_{db}[k])^2 & k > 0 \end{cases}
\]  

(162)

3) Compute the standard deviation using Equation (163) as follows:

\[
\hat{\sigma}_{\text{CINR, db}} = \sqrt{x_{\text{CINR}, \text{db}}[k] - (x_{\text{CINR}, \text{db}}[k])^2}
\]

(163)

The averaging parameter \((\alpha_{\text{avg}})\) for CINR measurement may be sent as a DCD Message TLV 21 for physical CINR averaging. The averaging parameter \((\alpha_{\text{avg}})\) for HO CINR measurement may be sent as DCD Message TLV 121 for HO CINR averaging. Unless specified otherwise, the default averaging parameter \((\alpha_{\text{avg}})\) is 1/4. When the averaging parameter \((\alpha_{\text{avg}})\) is given to an SS through REP-REQ, this value shall be used only for deriving physical CINR estimates reported through REP-RSP and can be changed further only through another REP-REQ message. When the averaging parameter is given to an SS through CQICH Allocation IE, this value shall be used only for deriving physical CINR estimates reported through fast-feedback channel (CQICH) and can be changed further only through another CQICH Allocation IE. An averaging parameter value sent through DCD shall not override the averaging parameter value sent in a dedicated REP-REQ message or a CQICH Allocation IE.

**8.4.12.4 Optional frequency selectivity characterization**

In order to characterize the relationship between channel frequency selectivity and link performance in a compact form, the parameters of an effective CINR versus weighting parameter \(\beta\) curve can be sent from the SS to the BS using an unsolicited REP-RSP TLV. When requested by the BS, the SS shall compute a quadratic approximation of an effective CINR (dB) vs. \(\beta\) dB = \(10 \log(\beta)\) curve. The quadratic approximation is represented as: effective-CINR dB(\(\beta\) dB) = \(a + b \times \beta\) dB + \(c \times \beta^2\) dB. Where \(a, b,\) and \(c\) are the Y-intercept, linear, and quadratic parameters, respectively, that are to be estimated by the SS. The quadratic approximation is derived by performing a curve fit to an experimentally derived effective CINR versus \(\beta\) curve.

**8.4.13 Transmitter requirements**

**8.4.13.1 Tx power level control**

The transmitter shall support monotonic power level control of 45 dB (30 dB for license-exempt bands) minimum with single step size accuracy requirement specified in Table 542.

**Table 542—Single step size relative accuracy**

<table>
<thead>
<tr>
<th>Single step size (m)</th>
<th>Required relative accuracy</th>
</tr>
</thead>
<tbody>
<tr>
<td>(</td>
<td>m</td>
</tr>
<tr>
<td>(</td>
<td>m</td>
</tr>
<tr>
<td>(</td>
<td>m</td>
</tr>
<tr>
<td>(4\text{dB} &lt;</td>
<td>m</td>
</tr>
</tbody>
</table>
Two exception points of at least 10 dB apart are allowed over the 45 dB range, where in these two points an accuracy of up to ± 2 dB is allowed for any size step.

8.4.13.2 Transmitter spectral flatness

All requirements on the transmitter apply to the RF output connector of the equipment. For equipment with integral antenna only, a reference antenna with 0 dBi gain shall be assumed.

The average energy of the constellations in each of the \( n \) spectral lines shall deviate no more than indicated in Table 543. The absolute difference between adjacent subcarriers shall not exceed 0.4 dB; excluding intentional boosting or suppression of subcarriers, CSIT sounding symbols and PAPR reduction subchannels are not allocated.

<table>
<thead>
<tr>
<th>Spectral lines</th>
<th>Spectral flatness</th>

<td>±2/–4 dB from the measured energy averaged over all (N_{used}) active tones</td>
</tr>
</tbody>
</table>

The power transmitted at spectral line 0 shall not exceed –15 dB relative to total transmitted power.

These data shall be taken from the channel estimation step.

8.4.13.3 Transmitter constellation error and test method

To ensure that the receiver SNR does not degrade more than 0.5 dB due to the transmitter SNR, the relative constellation RMS error, averaged over subcarriers, OFDMA frames, and packets, shall not exceed a burst profile dependent value according to Table 544. When measuring the transmitter constellation error, it should be noted that if multiple permutation zones are present in a DL subframe, the pilot level may shift when transitioning from zone to zone as the BS attempts to maintain constant power density throughout the frame.

<table>

</tbody>
</table>
All measurement errors taken together shall be 10 dB less than the required noise level, i.e., if a specification is TX S/N = 10 dB, the measurement S/N should be at least 20 dB. For all PHY modes, measurements shall be taken with all nonguard subcarriers active and no PAPR reduction subchannels used.

8.4.13.3.1 RMS constellation error measurement for BS (DL)

The test may be performed in any permutation zone like PUSC. The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps:

a) The BS under test shall transmit all subchannels defined in the symbol structure (see 8.4.6).

b) Locate the Preamble.

c) Perform timing and frequency estimation.

d) Compensate the timing offset as estimated.

e) The received signal shall be de-rotated according to estimated frequency offset.

f) The complex channel response coefficients shall be estimated for each of the subcarriers.

g) Divide each subcarrier value by the complex estimated channel response coefficient.

h) For each data-carrying subcarrier, find the closest constellation point and compute the Euclidean distance from it.

i) Compute the RMS average of all errors in a packet, given by Equation (164).

8.4.13.3.2 RMS constellation error measurement for SS

The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps:

a) The SS under test shall transmit on part of the UL subchannels. Recommended value is 1/4 of the UL subchannels.

b) The tester will locate a complete UL subframe.

c) Perform timing and frequency estimation.

d) Compensate the timing offset as estimated.

e) The received signal shall be de-rotated according to estimated frequency offset.

f) Estimate the average channel according to the all transmitted subcarriers.

g) Divide each subcarrier value with a complex estimated channel response coefficient.

h) For each data-carrying subcarrier, find the closest constellation point and compute the Euclidean distance from it.

i) Compute the RMS average of all errors in a packet. It is given by Equation (164).

j) Normal RMS constellation error measurement shall be performed in scenarios where the number of modulated subcarriers is constant across symbols.

k) In case the number of subcarriers varies between symbols, it is recommended to measure RMS constellation error separately for symbols with different power levels.

8.4.13.3.3 Calculation of RMS constellation error

The RMS constellation error is calculated using Equation (149).
where

\[ \text{Error}_{RMS}^2 = \frac{1}{N_f} \sum_{i=1}^{N_f} \left( \sum_{j=1}^{L_p} \sum_{k \in S} [(I(i, j, k) - I_0(i, j, k))^2 + (Q(i, j, k) - Q_0(i, j, k))^2] \right) \]

\[ \sum_{j=1}^{L_p} \sum_{k \in S} [I_0(i, j, k)^2 + Q_0(i, j, k)^2] \]

\[ (164) \]

where

- \( L_p \) is the length of the packet
- \( N_f \) is the number of frames for the measurement
- \((I_0(i, j, k), Q_0(i, j, k))\) denotes the ideal symbol point of the \( i \)-th frame, \( j \)-th OFDMA symbol of the frame, \( k \)-th subcarrier of the OFDMA symbol in the complex plane
- \((I(i, j, k), Q(i, j, k))\) denotes the observed point of the \( i \)-th frame, \( j \)-th OFDMA symbol of the frame, \( k \)-th subcarrier of the OFDMA symbol in the complex plane
- \( S \) is the group of modulated data subcarriers where the measurement is performed

### 8.4.13.3.4 Unmodulated subcarrier errors for SS

Unmodulated subcarrier errors is a measure of the amount of noise emitted by the SS on the unmodulated subcarriers (within the used subcarriers range). The measure is relative to the power emitted by the SS on the modulated subcarriers.

a) The SS under test shall transmit on part of the UL subchannels.
b) The tester will locate a complete UL subframe.
c) Perform timing and frequency estimation.
d) Compensate the timing offset as estimated.
e) The received signal shall be de-rotated according to estimated frequency offset.
f) The unmodulated subcarrier errors (relative to the transmitted power) shall be measured according to Equation (165).
g) The value of the unmodulated subcarrier error shall not exceed the maximum values defined in Table 544 and \( 10 \times \log_{10}(\frac{S_u}{S}) \).

\[ \text{Error}_{RMS}^2 = \frac{1}{N_f} \sum_{i=1}^{N_f} \left( \sum_{j=1}^{L_p} \sum_{k \in S} [(I(i, j, k))^2 + (Q(i, j, k))^2] \right) \]

\[ \sum_{j=1}^{L_p} \sum_{k \in S} [I_0(i, j, k)^2 + Q_0(i, j, k)^2] \]

\[ (165) \]

where

- \( L_p \) is the length of the packet
- \( N_f \) is the number of frames for the measurement
- \((I_0(i, j, k), Q_0(i, j, k))\) denotes the ideal symbol point of the \( i \)-th frame, \( j \)-th OFDMA symbol of the frame, \( k \)-th subcarrier of the OFDMA symbol in the complex plane
- \((I(i, j, k), Q(i, j, k))\) denotes the observed point of the \( i \)-th frame, \( j \)-th OFDMA symbol of the frame, \( k \)-th subcarrier of the OFDMA symbol in the complex plane
- \( S \) is the group of modulated data subcarriers where the measurement is performed
the group of the unmodulated data subcarriers. It includes all subcarriers in the range 0 \ldots N_{\text{used}} - 1, except the DC subcarrier and the modulated subcarriers (in \(S\)).

### 8.4.13.4 Transmitter reference timing accuracy

At the BS, the transmitted DL radio frame shall be time-aligned with the 1pps timing pulse (8.4.10.1.1). The start of the preamble symbol, excluding the CP duration, shall be time aligned with 1pps timing pulse when measured at the antenna port.

At the MS, upon close-loop adjustments of Tx and Rx timings from BS through CDMA ranging methods during network entry and periodic ranging, the MS obtains the system time reference. Thereafter, the MS shall maintain the relative time reference when measured at the antenna port.

### 8.4.14 Receiver requirements

All requirements on the receiver apply to the RF input connector of the equipment. For equipment with internal antennas only, a reference antenna with 0 dBi gain shall be assumed.

### 8.4.14.1 OFDMA PHY requirements for enhanced HO performance

#### 8.4.14.1.1 Receiver sensitivity

The BER measured after FEC shall be less than \(10^{-6}\) at the power levels given by Equation (166) for standard message and test conditions. The minimum input levels are measured as follows:

- Using the defined standardized message packet formats.
- Using an AWGN channel.

The receiver minimum sensitivity level, \(R_{SS}\), is derived according to Equation (166).

\[
R_{SS} = -114 + SNR_{Rx} - 10 \times \log_{10}(R) + 10 \times \log_{10}\left(\frac{F_S \times N_{\text{used}} \times 10^{-6}}{N_{\text{FFT}}}\right) + \text{ImpLoss} + NF
\]  \hspace{1cm} (166)

where

- \(SNR_{Rx}\) is the receiver SNR as per Table 545
- \(R\) is the repetition factor as described in 8.4.9
- \(F_S\) is the sampling frequency in Hz
- \(\text{ImpLoss}\) is the implementation loss, which includes nonideal receiver effects such as channel estimation errors, tracking errors, quantization errors, and phase noise. The assumed value is 5 dB.
\(NF\) is the receiver noise figure, referenced to the antenna port. The assumed value is 8 dB.

### Table 545—Receiver SNR assumptions

<table>
<thead>
<tr>
<th>Modulation</th>
<th>Coding rate</th>
<th>Receiver SNR (dB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>QPSK</td>
<td>1/2</td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>3/4</td>
<td>8</td>
</tr>
<tr>
<td>16-QAM</td>
<td>1/2</td>
<td>10.5</td>
</tr>
<tr>
<td></td>
<td>3/4</td>
<td>14</td>
</tr>
<tr>
<td>64-QAM</td>
<td>2/3</td>
<td>18</td>
</tr>
<tr>
<td></td>
<td>3/4</td>
<td>20</td>
</tr>
</tbody>
</table>

Note that these SNR values are derived in an AWGN environment, and assume that a tail-biting convolutional code is used.

Test messages for measuring Receiver Sensitivity shall be based on a continuous stream of MAC PDUs, each with a payload consisting of a \(R\) times repeated sequence \(S_{\text{modulation}}\). For each modulation, a different sequence applies:

- \(S_{\text{QPSK}} = [0x E4, 0xB1, 0xE1, 0xB4]\)
- \(S_{16-\text{QAM}} = [0xA8, 0x20, 0xB9, 0x31, 0xEC, 0x64, 0xFD, 0x75]\) (167)
- \(S_{64-\text{QAM}} = [0xB6, 0x93, 0x49, 0xB2, 0x83, 0x08, 0x96, 0x11, 0x41, 0x92, 0x01, 0x00, 0xBA, 0xA3, 0x8A, 0x9A, 0xB2, 0x83, 0xE7, 0x15, 0x51, 0xD3, 0x05, 0x10, 0xDB, 0x25, 0x92, 0xF7, 0x97, 0x59, 0xF3, 0x87, 0x18, 0xBE, 0xB3, 0xCB, 0x9E, 0x31, 0xC3, 0xDF, 0x35, 0xD3, 0xFB, 0xA7, 0x9A, 0xFF, 0xB7, 0xDB]\)

For each mandatory test message, the \((R,S_{\text{modulation}})\) tuples that shall apply are as follows:

- Short length test message payload (288 data bytes): \((72,S_{\text{QPSK}}), (36,S_{16-\text{QAM}}), (6,S_{64-\text{QAM}})\)
- Mid length test message payload (864 data bytes): \((216,S_{\text{QPSK}}), (108,S_{16-\text{QAM}}), (18,S_{64-\text{QAM}})\)
- Long length test message payload (1536 data bytes): \((384,S_{\text{QPSK}}), (192,S_{16-\text{QAM}}), (32,S_{64-\text{QAM}})\)

The test condition requirements are as follows:

- Ambient room temperature
- Shielded room
- Conducted measurement at the RF port if available
- Radiated measurement in a calibrated test environment if the antenna is integrated
- CC FEC is enabled

The test shall be repeated for each test message length and for each \((R,S_{\text{modulation}})\) tuple as identified above, using the mandatory FEC scheme. The results shall meet or exceed the sensitivity requirements set out in Equation (166).
8.4.14.1.2 MS UL Tx time tracking accuracy

With the time reference MS maintained in 8.4.13.4, MS shall autonomously adjust UL Tx timing according to the timing advances and retards of the DL in the preamble detected at the MS antenna port. The autonomous timing reference shall be tracked at antenna port without BS close-loop timing control.

At the MS, the transmitted radio frame shall be time-aligned with the network specified UL frame boundary. At zero timing advance and retard setting, the start of the first UL data symbol, excluding the CP duration, shall be time aligned with the specified UL frame boundary relative to the DL arrival time when measured at the antenna port without BS close-loop control.

8.4.14.1.3 MS autonomous neighbor cell scanning

If an MS supports FBSS/MDHO capability as defined in 11.7.12.5, the MS shall support autonomous neighbor cell scanning procedure according to the following. The MS may also perform normal scanning procedures as defined in 6.3.21.1.2. Autonomous scanning may be initiated by the MS with or without a trigger.

For autonomous scanning procedure, the MS shall perform neighbor cell scanning via preamble detection for neighbor cells in the same carrier frequency. The MS shall maintain the signal quality database for neighbor cells without being instructed by the BS.

8.4.14.2 Receiver adjacent and nonadjacent channel rejection

The adjacent channel rejection and alternate channel rejection shall be measured by setting the desired signal’s strength 3 dB above the rate dependent receiver sensitivity [see Equation (166)] and raising the power level of the interfering signal until the specified error rate is obtained. The power difference between the interfering signal and the desired channel is the corresponding adjacent channel rejection. The interfering signal in the adjacent channel shall be a conforming OFDMA signal, not synchronized with the signal in the channel under test. For nonadjacent channel testing the test method is identical except the interfering channel shall be any channel other than the adjacent channel or the co-channel.

For the PHY to be compliant, the minimum rejection shall exceed the limits in Table 546.

<table>
<thead>
<tr>
<th>Table 546—Adjacent and nonadjacent channel rejection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modulation/coding</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td>16-QAM-3/4</td>
</tr>
<tr>
<td>64-QAM-3/4</td>
</tr>
</tbody>
</table>

The requirements of Table 546 are applicable only to the mandatory Convolutional Encoding mode.

8.4.14.3 Receiver maximum input signal

8.4.14.3.1 SS receiver maximum input signal

The SS receiver shall be capable of decoding a maximum on-channel signal of –30 dBm.
8.4.14.3.2 BS receiver maximum input signal

The BS receiver shall be capable of decoding a maximum on-channel signal of –45 dBm.

8.4.14.4 Receiver maximum tolerable signal

8.4.14.4.1 SS receiver maximum tolerable signal

The SS receiver shall tolerate a maximum signal of 0 dBm without damage.

8.4.14.4.2 BS receiver maximum tolerable signal

The BS receiver shall tolerate a maximum signal of –10 dBm without damage.

8.4.15 Frequency control requirements

8.4.15.1 Center frequency and symbol clock frequency tolerance

At the BS, the transmitted center frequency, receive center frequency, and the symbol clock frequency shall be derived from the same reference oscillator. At the BS, the reference frequency accuracy shall be better than ±2 × 10⁻⁶.

At the SS, both the transmitted center frequency and the sampling frequency shall be derived from the same reference oscillator. Thereby, the SS UL transmission shall be locked to the BS so that its center frequency shall deviate no more than 2% of the subcarrier spacing compared to the BS center frequency.

During the synchronization period, the SS shall acquire frequency synchronization within the specified tolerance before attempting any UL transmission. During normal operation, the SS shall track the frequency changes by estimating the DL frequency offset and shall defer any transmission if synchronization is lost. To determine the Tx frequency, the SS shall accumulate the frequency offset corrections transmitted by the BS (e.g., in RNG-RSP message) and may add to the accumulated offset an estimated UL frequency offset based on the DL signal.

8.4.16 Optional HARQ support

The following optional modes exist for HARQ

— Incremental redundancy for CTC—specified in 6.3.17 and in 8.4.9.2.3.5.
— Incremental redundancy for CC (convolutional code)—specified in 8.4.16.2 and 8.4.9.2.1.1.
— Chase combining for all coding schemes specified in 8.4.16.1

These modes can be supposed by the normal map and the HARQ map.

8.4.16.1 Optional Chase HARQ support

The optional Chase HARQ scheme enables BS and SS to enhance performance of HARQ-enabled connection by means of chase combining scheme. This scheme is supported for all coding schemes. Each burst is appended with a CRC that is checked by the receiver. An UL and a DL ACK channels are defined (see 8.4.16.3 and 8.4.5.4.22). The receiver replies with an ACK in the corresponding ACK channel if the decoding succeeded and with a NACK if the decoding failed.

If the burst was not ACK-ed, the transmitter may transmit a burst with exactly the same data contents again. The receiver may combine the newly received burst with the formerly received burst(s) to enhance decoding performance.
8.4.16.1.1 HARQ retransmission process

The process of retransmissions is controlled by the BS using the ACID (ARQ Channel ID) and AI_SN fields in the DL and UL maps. Each HARQ channel (indicated by specific ACID of 0–15) is managed separately.

When the AI_SN field in the HARQ channel remains the same between two HARQ burst allocations, it indicates retransmission. In this case, the transmitter is required to retransmit the same data that was transmitted using the same ACID and AI_SN. The burst profile of the retransmission shall be the same as in the first transmission; however, the level of boosting and repetition may be changed.

When the AI_SN field in the HARQ channel is changed, it indicates transmission of new data. In this case, the data stored in the transmitter and receiver for this ACID and the previously used AI_SN may be discarded.

8.4.16.1.2 CRC

Bursts transmitted using Chase HARQ shall include CRC of 16 bits. The CRC is appended to MAC data after padding (before partitioning to FEC blocks and encoding as defined in 8.4.9). Padding is done so that the total length after CRC concatenation matches the size of the burst indicated by the map.

The CRC shall be CRC16-CCITT, as defined in ITU-T Recommendation X.25, and it is calculated over all the bits in the burst, including data and padding. After adding CRC, the packet shall be partitioned into FEC blocks and applied to the randomizer. The randomization is performed on each FEC block including CRC, which means that for each FEC encoder block the randomizer shall be initialized independently.

This CRC shall be used for error detection and for ACK/NACK transmission.

8.4.16.1.3 Concurrent transmission of UL HARQ bursts

The BS may allocate more than one UL HARQ burst for an SS (see 8.4.4.6). The maximal number of UL bursts supported by an HARQ-enabled SS is indicated by the capability field in 11.8.3.5.13 and includes both HARQ and non-HARQ bursts.

8.4.16.1.4 Encoding

When using Chase-HARQ with HARQ DL/UL IE in the normal maps, the encoding scheme is indicated by DIUC/UIUC code and the encoding process shall be the same as in non-HARQ transmission with the same DIUC/UIUC.

8.4.16.2 Optional IR HARQ for convolutional code

This mode of operation is similar to Chase HARQ (see 8.4.16.1). The specifications in 8.4.16.1 apply to this mode, except for the following differences:

a) An SPID field is supplied by the HARQ DL/UL MAP IE.

b) The value of SPID may be arbitrarily changed by the BS between retransmissions.

c) The encoding process is based on the non-HARQ coding scheme, except for the changes indicated in 8.4.9.2.1.1.

8.4.16.3 UL ACK channel

The UL ACK (Acknowledgment) provides feedback for DL Hybrid ARQ. This channel shall only be supported by SS supporting HARQ. The SS transmits ACK or NAK feedback for DL packet data. One ACK
channel occupies a half subchannel, which is three pieces of $3 \times 3$ UL tile in the case of optional PUSC or three pieces of $4 \times 3$ UL tile in the case of PUSC. The even half subchannel consists of Tile(0), Tile(2), and Tile(4). The odd half subchannel consists of Tile(1), Tile(3), and Tile(5).

The Acknowledgment bit of the $n$-th ACK channel shall be 0 (ACK) if the corresponding DL packet has been successfully received; otherwise, it shall be 1 (NAK). This 1 bit is encoded into a length 3 codeword over 8-ary alphabet for the error protection as shown in Table 547.

<table>
<thead>
<tr>
<th>ACK 1-bit symbol</th>

</tr>
</tbody>
</table>

The UL ACK channel is orthogonally modulated with QPSK symbols. Let $M_{n,8m+k}$ ($0 \leq k \leq 7$) be the modulation symbol index of the $k$-th modulation symbol in the $m$-th UL tile of the $n$-th UL ACK channel. The possible modulation patterns composed of $M_{n,8m}, M_{n,8m+1}, \ldots, M_{n,8m+7}$ in the $m$-th tile of the $n$-th UL ACK channel are defined in Table 548.

<table>

</tbody>
</table>

where
\[ P_0 = \exp\left( j \cdot \frac{\pi}{4} \right) \]

\[ P_1 = \exp\left( j \cdot \frac{3\pi}{4} \right) \]

\[ P_2 = \exp\left( -j \cdot \frac{3\pi}{4} \right) \]

\[ P_3 = \exp\left( -j \cdot \frac{\pi}{4} \right) \]

\( M_{n,8m+k} \) is mapped to UL ACK channel tile as shown in Figure 304 for PUSC UL subchannel and in Figure 305 for optional PUSC UL subchannel. An UL ACK channel is mapped to half subchannel composed of 3 tiles. In the figures, subcarrier index increases from left to right.
8.5 WirelessHUMAN specific components

8.5.1 Channelization

The channel center frequency shall follow Equation (168):

\[
\text{Channel center frequency (MHz)} = 5000 + 5 \, n_{ch}
\]  

(168)

where \( n_{ch} = 0,1,...,199 \) is the Channel Nr. This definition provides an 8-bit unique numbering system for all channels, with 5 MHz spacing, from 5 GHz to 6 GHz. This provides flexibility to define channelization sets for current and future regulatory domains. The set of allowed channel numbers is shown in Table 549 for...
two regulatory domains. The support of any individual band in the table is not mandatory, but all channels within a band shall be supported.

Figure 306 depicts the 20 MHz channelization scheme listed in Table 549. Channelization has been defined to be compatible with IEEE Std 802.11a-1999 for interference mitigation purposes, even though this results in less efficient spectrum usage in the middle Unlicensed National Information Infrastructure (U-NII) band.

Figure 306—Channelization, 20 MHz
8.5.2 Tx spectral mask

The transmitted spectral density of the transmitted signal shall fall within the spectral mask as shown Figure 307 and Table 550. The measurements shall be made using 100 kHz resolution bandwidth and a 30 kHz video bandwidth. The 0 dBr level is the maximum power allowed by the relevant regulatory body.

9. Configuration

9.1 SS IP addressing used on secondary management connection

9.1.1 DHCP fields used by the SS

The following fields shall be present in the DHCP request from the SS and shall be set as described below and encoded as per IETF RFC 2131:

- The hardware type (htype) shall be set to 1 (Ethernet).
- The hardware length (hlen) shall be set to 6.
- The client hardware address (chaddr) shall be set to the 48-bit MAC address associated with the RF interface of the SS.
- The “client identifier” option shall be included, with the hardware type set to 1, and the value set to the same MAC address as the chaddr field.
- The “parameter request list” option shall be included. The option codes that shall be included in the list are follows:
  - Option code 1 (Subnet Mask)
  - Option code 2 (Time Offset)
  - Option code 3 (Router Option)
  - Option code 4 (Time Server Option)
  - Option code 7 (Log Server Option)
  - Option code 60 (Vendor Class Identifier)—A compliant SS shall send the following ASCII coded string in Option code 60: “802.16.”

The following fields are expected in the DHCP response returned to the SS. The SS shall configure itself based on the DHCP response.

- The IP address to be used by the SS (yiaddr).
- The IP address of the TFTP server for use in the next phase of the bootstrap process (siaddr).
- If the DHCP server is on a different network (requiring a relay agent), then the IP address of the relay agent (giaddr).
  NOTE—This may differ from the IP address of the first hop router.
- The name of the SS configuration file to be read from the TFTP server by the SS (file).
- The subnet mask to be used by the SS (Subnet Mask, option 1).
- The time offset of the SS from UTC (Time Offset, option 2). This is used by the SS to calculate the local time for use in time-stamping error logs.
- A list of addresses of one or more routers to be used for forwarding SS-originated IP traffic (Router Option, option 3). The SS is not required to use more than one router IP address for forwarding.
- A list of time servers (IETF RFC 868) from which the current time may be obtained (Time Server Option, option 4).
- A list of SYSLOG servers to which logging information may be sent (Log Server Option, option 7).

9.1.2 Mobile IP v4 fields used by the MS

If Mobile IP v4 is used to obtain an address for the secondary management connection, the following fields shall be present in the Mobile IP registration request sent from the MIP client residing in the MS and shall be set as described below and encoded according to IETF RFC 3344.

a) When the MS (or Mobile Node) attempts to obtain an IP address dynamically, the home address field shall be set to “0.0.0.0”.

Copyright © 2009 IEEE. All rights reserved.
b) When the MS attempts to obtain an IP address in the visited network, the home agent address field shall be set to “0.0.0.0”. On the other hand, when the MS attempts to obtain an IP address in the home network, the home agent address field shall be set to “255.255.255.255”.

c) The Network Access Identifier (NAI) extension [IETF RFC 2789] shall be included for identifying the Mobile IP user.

d) The Challenge extension shall be included [IETF RFC 3012], if the Challenge extension is included in the Agent Advertisement message.

e) A 128-bit key may be shared between an MS and an ASA server during the initial Mobile IP registration, and the MS-ASA Authentication extension may be generated based on the shared key [IETF RFC 3012].

The following fields are expected in the Mobile IP registration response returned to the MIP Client residing in the MS. The MS shall configure itself based on the Mobile IP registration response.

— The home address to be used by the MS.
— The MS’s NAI extension to identify a Mobile IP user [IETF RFC 2789].
— The challenge extension if the foreign agent supports more strong security.
— The MS and home agent authentication extension for authenticating the home agent.
— The Key Reply extensions for security between the MS and the home agent, and between the MS and foreign agent, if the MS requests keys between the MS and the home agent, and between the MS and the foreign agent.

9.2 SS Configuration file

9.2.1 SS binary configuration file format

The SS-specific configuration data shall be contained in the SS configuration file that is downloaded to the SS via TFTP. It shall consist of a number of configuration settings (1 per parameter), each in a TLV encoded form (see Clause 11). Note that SSs are not required to need a configuration file. In this case, the configuration file name will not be present in the DHCP response.

Configuration settings are divided into three types as follows:

— Standard configuration settings that shall be present
— Standard configuration settings that may be present
— Vendor-specific configuration settings

SSs shall be capable of processing all standard configuration settings. SSs shall ignore any configuration setting in the configuration file that it cannot interpret. To allow uniform management of SSs conformant to this specification, conformant SSs shall support a 8192 byte configuration file at a minimum.

Integrity of the configuration file information is provided by the SS message integrity check (MIC). The SS MIC is a digest that ensures the data sent from the provisioning server were not modified en route. This is not an authenticated digest (i.e., it does not include any shared secret).

The SS MIC shall immediately be followed by the End of Data marker equal to 0xFF.

In case the file is a noninteger number of 32-bit words, the file shall be padded with zeros until the next 32-bit boundary.

The file structure is shown in Figure 308.
9.2.2 Configuration file settings

The following configuration settings shall be included in the configuration file and shall be supported by all SSs:

- SS MIC Configuration Setting
- TFTP Server Timestamp

The following configuration settings may be included in the configuration file and if present shall be supported by all SSs:

- Software Upgrade Filename Configuration Setting (see 11.2.2)
- Software Server IP Address (see 11.2.3)
- Vendor-specific configuration settings

9.2.3 Configuration file creation

The sequence of operations required to create the configuration file is as shown in Figure 309, Figure 310, and Figure 311.

a) Create the TLV entries for all the parameters required by the SS.

```plaintext
| type, length, value for parameter 1 |
| type, length, value for parameter 2 |
| type, length, value for parameter n |
```

Figure 309—Create TLV entries for parameters required by the SS
b) Calculate the SS MIC configuration setting as defined in 9.2.3.1 and add to the file following the last parameter using code and length values defined for this field.

```
<table>
<thead>
<tr>
<th>type, length, value for parameter 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>type, length, value for parameter 2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>type, length, value for parameter n</td>
</tr>
<tr>
<td>type, length, value for SS MIC</td>
</tr>
</tbody>
</table>
```

Figure 310—Add SS MIC

c) Add the end of data marker and pad with zeros to next 32-bit boundary if necessary.

```
<table>
<thead>
<tr>
<th>type, length, value for parameter 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>type, length, value for parameter 2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>type, length, value for parameter n</td>
</tr>
<tr>
<td>type, length, value for SS MIC</td>
</tr>
<tr>
<td>end of data marker</td>
</tr>
</tbody>
</table>
```

Figure 311—Add end of data marker and pad

### 9.2.3.1 SS MIC calculation

The SS MIC configuration setting shall be calculated by performing a SHA-1 digest over the bytes of the configuration setting fields. It is calculated over the bytes of these settings as they appear in the TFTPed image, without regard to TLV ordering or contents. There are two exceptions to this disregard of the contents of the TFTPed image:

- The bytes of the SS MIC TLV itself are omitted from the calculation. This includes the type, length, and value fields.
- On receipt of a configuration file, the SS shall recompute the digest and compare it to the SS MIC configuration setting in the file. If the digests do not match, then the configuration file shall be discarded.

### 9.3 ASN.1 Management Information Base

The Management Information Base for BSs and SSs is defined as ASN.1 (refer to [ISO/IEC ASN.1]) MIB modules, in conformance with IETF RFC 2578. The implementation of the ASN.1 MIB modules is mandatory for all BSs. The implementation of the ASN.1 MIB modules is mandatory for SSs that are managed using the SNMP protocol.
The specific requirements for implementation of individual MIB modules are defined in 9.3.3. The specific requirements for implementation of individual MIB objects in each MIB module are defined in conformance statements of the MIB modules.

Table 551 lists all defined ASN.1 MIB modules, their status and module identity OID. The subsequent subclauses give more details about each defined MIB module.

Table 551—List of ASN.1 MIB Modules

9.3.1 WMAN-IF-MIB module

The WMAN-IF-MIB MIB module is obsolete. Equipment compliant to this standard shall implement the WMAN-IF2-BS-MIB, WMAN-IF2M-BS-MIB, WMAN-IF2F-BS-MIB, WMAN-IF2-SS-MIB, and WMAN-IF2-TC-MIB modules rather than the WMAN-IF-MIB MIB module. The WMAN-IF-MIB MIB module was originally introduced in the amendment IEEE Std 802.16f-2005 to define management objects relevant to a fixed broadband wireless access system specified in IEEE Std 802.16-2004.

The WMAN-IF-MIB MIB module is identified by the module identity name wmanIfMib and is accessible through the following OID:

9.3.2 WMAN-DEV-MIB module

The WMAN-DEV-MIB MIB module defines management objects relevant to devices implementing the broadband wireless access air interface defined in this standard. The objects of this MIB module may refer explicitly to terms defined in the standard (e.g., configuration file encodings) but mainly provide the mandatory support required to manage the devices implementing the IEEE 802.16 interface.
The BS shall implement this MIB module. SS shall implement this MIB module if it is managed using SNMP protocol.

The WMAN-DEV-MIB MIB module is identified by module identity name wmanDevMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso8802}(8802).\text{wman}(16).\text{wmanDevMib}(1)
\]

### 9.3.3 WMAN-IF2-BS-MIB module

The WMAN-IF2-BS-MIB MIB module defines all management objects that are common to all broadband wireless interfaces as defined in this standard.

The BS shall implement this MIB module.

The WMAN-IF2-BS-MIB MIB module is identified by module identity name wmanIf2BsMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso8802}(8802).\text{wman}(16).\text{wmanIf2BsMib}(2)
\]

### 9.3.4 WMAN-IF2M-BS-MIB module

The WMAN-IF2M-BS-MIB MIB module defines all management objects that are specific to mobile broadband wireless interfaces as defined in this standard.

The BS shall implement this MIB module if it supports mobility.

The WMAN-IF2M-BS-MIB MIB module is identified by module identity name wmanIf2mBsMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso8802}(8802).\text{wman}(16).\text{wmanIf2mBsMib}(3)
\]

### 9.3.5 WMAN-IF2F-BS-MIB module

The WMAN-IF2F-BS-MIB MIB module defines all management objects that are specific to fixed broadband wireless interfaces as defined in this standard.

The BS shall implement this MIB module if it supports fixed BWA.

The WMAN-IF2F-BS-MIB MIB module is identified by module identity name wmanIf2fBsMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso8802}(8802).\text{wman}(16).\text{wmanIf2fBsMib}(4)
\]

### 9.3.6 WMAN-IF2-SS-MIB module

The WMAN-IF2-SS-MIB MIB module defines all management objects for all broadband wireless interfaces as defined in this standard for direct management of SS.

The SS shall implement this MIB module if it is managed using SNMP protocol.
The WMAN-IF2-SS-MIB MIB module is identified by module identity name wmanIf2SsMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso}8802(8802).\text{wman}(16).\text{wmanIf2SsMib}(5)
\]

### 9.3.7 WMAN-IF2-TC-MIB module

The WMAN-IF2-TC-MIB MIB module defines TEXTUAL-CONVENTIONS to be imported by WMAN-IF2 MIBs.

The WMAN-IF2-TC-MIB MIB module is identified by module identity name wmanIf2TcMib and shall be accessed through the following OID:

\[
\text{iso}(1).\text{std}(0).\text{iso}8802(8802).\text{wman}(16).\text{wmanIf2TcMib}(6)
\]

### 9.4 Management protocols

The protocols used for management purposes between an external entity and an IEEE 802.16 entity are not in the scope of this standard. Refer to Annex L for example deployments of management frameworks. Whichever framework is deployed, the ASN.1 MIBs serve the purpose of a protocol neutral reference model of the management operations that may be performed on an IEEE 802.16 entity.

#### 9.4.1 SNMP

SNMP is a protocol to access the managed objects in a BS and SS. BSs and Ss implementing SNMP management protocol are assumed to comply with the following requirements. The support of SNMP is compliant to SNMPv2, but is backward compatible to SNMPv1 through appropriate translation. The SNMP agent optionally supports for SNMPv3. If an agent implements SNMPv3, it is assumed to implement at least all the mandatory groups of the standard MIBs required for SNMPv3: RFC3410, RFC3411, RFC3412, RFC3413, RFC3414, and RFC3415 as well as the MIB defining coexistence between SNMPv1, v2 and v3 in RFC3584. The SNMPv3 framework may be considered as a mechanism to flexibly control access to this MIB module, and mitigate security vulnerability. The SNMP agent is assumed to support RFC3418.

#### 9.4.1.1 Relationship with interface MIB

This subclause describes the integration with MIB-II under Interface Group MIB defined in IETF RFC 2863.

#### 9.4.1.1.1 MIB-2 integration

The Internet Assigned Number Authority (IANA) has assigned the following ifTypes:

\[
\text{IANAifType ::= TEXTUAL-CONVENTION}
\]

\[
\text{SYNTAX INTEGER \{}
\]

\[
\text{propBWAp2Mp (184), -- prop broadband wireless access point to multipoint}
\]

\[
\text{-- use of this ifType for IEEE 802.16 WMAN}
\]

\[
\text{-- interface as per IEEE Std 802.16f is deprecated,}
\]

\[
\text{-- and ifType ieee80216WMAN should be used}
\]

\[
\text{-- instead.}
\]

\[
\text{ieee80216WMAN (237), -- IEEE 802.16 WMAN interface}
\]

\[
\text{\}}
\]
The interface type “propBWAp2Mp” (ifType 184) originally introduced in the amendment IEEE 802.16f-2005 is deprecated. All new implementations of SNMP agents should use the interface type “ieee80216WMAN” (ifType 237). For backwards compatibility purposes, SNMP managers shall accept the deprecated interface type.

9.4.1.1.2 Usage of MIB-II tables

“Interfaces” group of MIB-II, in RFC2863, has been designed to manage various sub-layers (e.g., MAC and PHY) beneath the internetwork-layer for numerous media-specific interfaces. The implementation of ifTable in SNMP managed BS and SS is mandatory.

The implementation of the ifTable for BS shall create one row for each BS sector. Each BS sector shall support a different MAC version (see 11.1.3). The following recommendations must be applied to each row defining a BS sector:

- ifIndex value is implementation specific
- ifType shall be set to ieee80216WMAN (value of 237 as defined in 9.4.1.1.1)
- ifSpeed shall be set to “0”
- ifPhysAddress shall be set to the Base Station ID of the BS sector
- ifOperStatus is “up(1)” as soon as the BS has started to transmit DCD messages allowing an SS to synchronize to a downlink channel. IfOperStatus “dormant(5),” does not apply to a BS
- All other columnar objects shall be initialized as specified in IETF RFC 2863

Table 552 shows an example of the usage of ifTable objects for base station

<table>
<thead>
<tr>
<th>ifTable</th>
<th>ifIndex</th>
<th>ifType (IANA)</th>
<th>ifSpeed</th>
<th>ifPhysAddress</th>
<th>ifAdminStatus</th>
<th>ifOperStatus</th>
</tr>
</thead>
<tbody>
<tr>
<td>BS Sector 1</td>
<td>1</td>
<td>ieee80216WMAN</td>
<td>0</td>
<td>BS station ID</td>
<td>Administra-</td>
<td>Operational</td>
</tr>
<tr>
<td>BS Sector 2</td>
<td>2</td>
<td>ieee80216WMAN</td>
<td>0</td>
<td>BS station ID</td>
<td>Administra-</td>
<td>Operational</td>
</tr>
<tr>
<td>BS Sector 3</td>
<td>3</td>
<td>ieee80216WMAN</td>
<td>0</td>
<td>BS station ID</td>
<td>Administra-</td>
<td>Operational</td>
</tr>
<tr>
<td>Ethernet</td>
<td>4</td>
<td>ethernetCsmacd</td>
<td>Interface Speed</td>
<td>MAC address</td>
<td>Administra-</td>
<td>Operational</td>
</tr>
</tbody>
</table>

Table 552 shows an example of the usage of ifTable for BS that supports multiple sectors. Each sector may support one of the MAC/PHY interfaces as defined in 11.1.3.

The implementation of the ifTable for SS shall create one row for each SS WirelessMAN interface. Additional rows may be necessary to support other network interfaces, such as Ethernet. The following recommendations shall be applied to each row:

- ifIndex value is implementation specific
- ifType shall be set to ieee80216WMAN (value of 237 as defined in subclause 9.4.1.1.1)
- ifSpeed shall be set to “0”
- ifPhysAddress shall be set to the SS MAC Address (of the WirelessMAN interface)
- ifOperStatus is “up(1)” as soon as the SS is capable of detecting downlink PHY frames
- All other columnar objects shall be initialized as specified in IETF RFC 2863

---

24The data rate in bits/s varies dynamically between zero and a theoretical maximum and there is no concept of an interface speed in the IEEE 802.16 standards. In such cases, according the IETF RFC 2863, the ifSpeed should be set to zero.
Table 553—Example of the Usage of ifTable objects for subscriber station

<table>
<thead>
<tr>
<th>ifTable</th>
<th>ifIndex</th>
<th>ifType (IANA)</th>
<th>ifSpeed</th>
<th>ifPhysAddress</th>
<th>ifAdminStatus</th>
<th>ifOperStatus</th>
</tr>
</thead>
<tbody>
<tr>
<td>SS</td>
<td>1</td>
<td>ieee80216WMAN</td>
<td>0</td>
<td>SS MAC address</td>
<td>Administration Status</td>
<td>Operational Status</td>
</tr>
<tr>
<td>Ethernet</td>
<td>2</td>
<td>ethernetCsmacd</td>
<td>Interface Speed</td>
<td>MAC address</td>
<td>Administration Status</td>
<td>Operational Status</td>
</tr>
</tbody>
</table>

Table 553 shows an example of the usage of ifTable for SS that may support one of the MAC / PHY interfaces as defined in 11.1.3.

Figure 312 shows a procedure describing how the BS can determine the MAC / PHY standard interface and capability a SS can support.
1) Receive RNG-REQ from SS / MS
2) If MAC version is IEEE Std 802.16-2004, then
   a) `wmanIf2BsSsMacVersion = ieee802Dot16Of2004`
   b) `wmanIf2mBsSsReqCapMobilityFeature = notSupported`
   c) Go to step 5)
3) Receive REG-REQ from SS/MS  
4) If Mobility Feature is supported, then  
   a) \text{wmanIfBsSsMacVersion} = \text{ieee802Dot16at2009}  
   b) \text{wmanIf2mBsSsReqCapMobilityFeature} = \text{Supported}  
   otherwise  
   c) \text{wmanIfBsSsMacVersion} = \text{ieee802Dot16at2009}  
   d) \text{wmanIf2mBsSsReqCapMobilityFeature} = \text{Not Supported}  
5) Continue network entry procedure  

\textbf{9.4.1.2 Events and traps}  

IEEE 802.16 WMAN MIBs defines objects for reporting events through mechanisms, such as traps and non-volatile logging. However, the definition and coding of events is vendor-specific. In order to assist the network operators who must troubleshoot multi-vendor equipment, the circumstances and meaning of each event should be reported as human-readable text. Therefore, the trap definitions should include the event reason encoded as display string, and is shown in the following example.  

\begin{verbatim}  
      trapName NOTIFICATION-TYPE  
        OBJECTS {ifIndex,  
                   eventReason,  
                   other useful objects  
                 }  
        MAX-Access   read-only  
        STATUS       current  
        DESCRIPTION  
          "trap description"  
      ::= { Object Id }.  
\end{verbatim}
10. Parameters and constants

10.1 Global values

The BS and SS shall meet the requirements contained in Table 554.

</tbody>
</table>
For the purposes of protocol testing, it is useful to run the privacy protocol with timer values well below the low end of the operational ranges. The shorter timer values “speed up” privacy’s clock, causing privacy protocol state machine events to occur far more rapidly than they would under an “operational” configuration. While privacy implementations need not be designed to operate efficiently at this accelerated privacy pace, the protocol implementation should operate correctly under these shorter timer values. Table 557 provides a list of shortened parameter values that are likely to be employed in protocol conformance and certification testing.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Shortened value</th>
<th>[min (s)]</th>
</tr>
</thead>
<tbody>
<tr>
<td>AK Lifetime</td>
<td>5 (300)</td>
<td></td>
</tr>

<td>Authorization Grace Time</td>
<td>1 (60)</td>
<td></td>
</tr>
<tr>
<td>TEK Grace time</td>
<td>1 (60)</td>
<td></td>
</tr>
</tbody>
</table>

The TEK Grace Time shall be less than half the TEK lifetime.

10.3 PHY-specific values

10.3.1 WirelessMAN-SC parameter and constant definitions

10.3.1.1 PS

For the WirelessMAN-SC PHY, a PS is the duration of four modulation symbols at the symbol rate of the DL transmission.

10.3.1.2 Symbol rate

The symbol rate shall be in the range 10–44.8 MBd, in increments of 100 kBD.

10.3.1.3 UL center frequency

The UL center frequency shall be a multiple of 250 kHz.

10.3.1.4 DL center frequency

The DL center frequency shall be a multiple of 250 kHz.

10.3.1.5 Tolerated poll jitter

For the 10–66 GHz PHY, the minimum value of the Tolerated Poll Jitter (see 11.13.12) shall be 3000 μs.

10.3.1.6 Allocation Start Time

Unit of Allocation Start Time shall be minislots from the start of the DL frame in which the UL-MAP message occurred.
10.3.1.7 Timing Adjust Units

The timing adjust units shall be \( \frac{1}{4} \) modulation symbols. During periodic ranging, the range of the value of this parameter shall be limited to \( \pm 2 \) modulation symbols.

10.3.2 Reserved

10.3.3 WirelessMAN-OFDM parameters and constant definitions

10.3.3.1 Uplink Allocation Start Time

The unit of allocation start time shall be PSs from the start of the DL frame in which the UL-MAP message occurred or from the start of the AAS zone if the UL MAP was transmitted in AAS zone. The minimum value specified for this parameter shall correspond to a point in the frame 1 ms after the last symbol of the UL-MAP.

10.3.3.2 PS

PSs are defined as in Equation (169).

\[
PS = \frac{4}{F_s}
\]  

(169)

10.3.3.3 Timing adjust units

The timing adjust units shall be \( \frac{1}{F_s} \).

10.3.4 WirelessMAN-OFDMA parameters and constant definitions

10.3.4.1 Uplink Allocation Start Time

The unit of allocation start time shall be PSs from the start of the DL frame in which the UL-MAP message occurred. The minimum value specified for this parameter shall refer to the time indicated by \( T_{proc} \) defined in Table 554.

\( F_s \) is the sampling frequency of the downlink.

10.3.4.2 PS

PSs are defined as Equation (170).

\[
PS = \frac{4}{F_s}
\]  

(170)

10.3.4.3 Timing adjust units

The timing adjust units shall be \( \frac{1}{F_s} \).

10.4 Well-known addresses and identifiers

There are several CIDs defined in Table 558 that have specific meaning. These identifiers shall not be used for any other purposes.

It is noted that the multicast CID may have a format with Reduced CID on HARQ region.
<table>
<thead>
<tr>
<th>CID</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ranging CID</td>
<td>0x0000</td>

<td>0xFE0–0xFEFE</td>
<td>For the DL multicast service, the same value is assigned to all MSs on the same channel that participate in this connection.</td>
</tr>
<tr>
<td>AAS Initial Ranging</td>
<td>0xFEFF</td>
<td>A BS supporting AAS shall use this CID when allocating an AAS ranging period (using AAS Ranging Allocation IE).</td>
</tr>
<tr>
<td>Multicast Polling</td>
<td>0xFF00–0xFFF9</td>
<td>A MS may be included in one or more multicast polling groups for the purpose of obtaining bandwidth via polling. These connections have no associated service flow.</td>
</tr>
<tr>
<td>Normal Mode Multicast</td>
<td>0xFFFA</td>
<td>Used in DL-MAP to denote bursts for transmission of DL broadcast information to normal mode MS.</td>
</tr>
<tr>
<td>Sleep Mode Multicast</td>
<td>0xFFFFB</td>
<td>Used in DL-MAP to denote bursts for transmission of DL broadcast information to sleep mode MS. May also be used in MOB_TRF-IND messages.</td>
</tr>
<tr>
<td>Idle Mode Multicast</td>
<td>0xFFFC</td>
<td>Used in DL-MAP to denote bursts for transmission of DL broadcast information to idle mode MS. May also be used in MOB_PAG-ADV messages.</td>
</tr>
<tr>
<td>Fragmentable Broadcast</td>
<td>0xFFFD</td>
<td>Used by the BS for transmission of management broadcast information with fragmentation. The fragment subheader shall use 11-bit FSN on this connection.</td>
</tr>
<tr>
<td>Padding</td>
<td>0xFFFE</td>
<td>Used for transmission of padding information by SS and BS.</td>
</tr>
<tr>
<td>Broadcast</td>
<td>0xFFFF</td>
<td>Used for broadcast information that is transmitted on a DL to all SS.</td>
</tr>
</tbody>
</table>
11. TLV encodings

The following TLV encodings shall be used for parameters in both the configuration file (Clause 9) and MAC Management messages (6.3.2.3). TLV tuples with Type values not specified in this standard or specified as “reserved” shall be silently discarded. The SS and BS shall silently discard any TLV with an unknown type number. The length of the Type field shall be one byte.

The format of the Length field shall be per the “definite form” of ITU-T X.690. Specifically, if the actual length of the Value field is less than or equal to 127 bytes, then

— The length of the Length field shall be one byte,
— The MSB of the Length field shall be set to 0, and
— The other 7 bits of the Length field shall be used to indicate the actual length of the value field in bytes.

If the length of the Value field is more than 127 bytes, then

— The length of the Length field shall be one byte more than what is actually used to indicate the length of the value field in bytes,
— The MSB of the first byte of the Length field shall be set to 1,
— The other 7 bits of the first byte of the Length field shall be used to indicate the number of additional bytes of the Length field (i.e., excluding the first byte), and
— The remaining bytes (i.e., excluding the first byte) of the Length field shall be used to indicate the actual length of the Value field.

NOTE—Uniqueness of TLV Type values is assured by identifying the groups of IEEE 802.16 entities (configuration file and/or MAC management messages) that share references to specific TLV encodings. Disjoint collections of TLVs are formed that correspond to each such functional grouping. Each set of TLVs that are explicitly defined to be members of a compound TLV structure form additional collections. Unique type values are assigned to the member TLV encodings of each collection.

An additional collection, the Common encodings, is defined that consists of TLV encodings that are referenced by more than one of the functional groups. The Type values of the TLV members of this collection are assigned to assure uniqueness across all collections. This is the only collection for which global uniqueness is guaranteed.

In cases where a collection contains TLV encodings that are PHY-specification-specific, subcollections are formed that contain these TLV encodings. Type values assigned to members of each subcollection are assigned so that the values are unique within the subcollection and with non-PHY-specification-specific members of the collection. Type values are not unique across PHY-specific subcollections.

TLV Type values are assigned in accordance with the following rules:

— Common encodings start at 149, subsequent values are assigned in descending order.
— For individual collections, non-PHY-specification-specific encodings start at 1, subsequent values are assigned in ascending order.
— For individual collections, PHY-specification-specific encodings start at 150, subsequent values are assigned in ascending order.

Unless otherwise indicated, bit 0 is the LSB of the least significant byte for all TLVs with length of multiple bytes.

11.1 Common encodings

Common TLV fields and their associated type codes are presented in Table 559.

### 11.1.1 Current Tx power

This parameter indicates the transmitted power used for the burst that carried the message. The parameter is reported in dBm and is quantized in 0.5 dBm steps ranging from –84 dBm (encoded 0x00) to 43.5 dBm (encoded 0xFF). Values outside this range shall be assigned the closest extreme. The parameter is only applicable to systems supporting the OFDM, or OFDMA PHY specifications. However, for the OFDM or OFDMA PHY, this value indicates the average transmitted power of each subcarrier for the burst that carried the message.
11.1.2 Authentication tuples

An authentication tuple shall be the last item in identified management messages.

When no authorization is negotiated between an MS and a BS as an authorization policy, all authentication tuples (i.e., CMAC-Tuple, HMAC-Tuple, and short HMAC-Tuple) shall be omitted from MAC management messages unless otherwise required by the negotiated authorization policy support (see 11.8.4.2).

11.1.2.1 HMAC tuple

This parameter contains the HMAC Key Sequence Number concatenated with an HMAC Digest used for message authentication. The HMAC Key Sequence Number is stored in the 4 LSBs of the first byte of the HMAC Tuple, and the 4 MSBs are reserved. The HMAC-Tuple attribute format is shown in Table 560 and Table 561. When PKM is disabled (see 11.7.8.6), the content of this field shall be ignored and the message considered authenticated.

### Table 560—HMAC Tuple definition

</tr>
</tbody>
</table>

11.1.2.2 CMAC Tuple

The CMAC Tuple attribute format is shown in Table 562 and Table 563.

A message received, that contains an CMAC Tuple, shall not be considered authentic if the length field of the tuple is incorrect, or if the locally computed value of the digest does not match the digest in the message.
NOTE—It would be appropriate for a MIB to increment an error count on receipt of a nonauthentic message so that management can detect an active attack.

Table 562—CMAC Tuple

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The CMAC tuple is added to the RNG-REQ message only during handover, secure location update or network re-entry from idle mode. This tuple shall be included in the messages if the MS and the BS share a valid AK.

11.1.2.3 Short-HMAC tuple

This parameter contains the HMAC Key Sequence Number concatenated with an HMAC Digest used for message authentication. The HMAC Key Sequence Number is stored in the 4 LSBs of the first byte of the HMAC Tuple, and the 4 MSBs are reserved. The HMAC Tuple attribute format is shown in Table 564 and Table 565.

Table 564—Short-HMAC tuple

</tr>
</tbody>
</table>
11.1.3 MAC version encoding

This parameter specifies the version of IEEE 802.16 to which the message originator conforms.

If the MAC version values exchanged between a BS and SS during network entry differ such that the BS version is greater than the SS version, the SS may attempt to perform normal operations. The BS may attempt to communicate with the SS per the version specified by the SS, or may decline to interoperate with the SS.

If the MAC version values exchanged between a BS and SS during network entry differ such that the BS version is smaller than the SS version, the BS may attempt to perform normal operations. The SS may attempt to communicate with the BS per the version specified by the BS, or may decline to interoperate with the BS.

</tbody>
</table>

11.1.4 Service flow descriptors

Information regarding the attributes of an UL or DL service flow shall be encapsulated in a compound structure identified by the appropriate TLV Type value. The contents of the compound structure are defined in 11.13.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>146</td>
<td>variable</td>
<td>Compound: DL service flow</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
<tr>
<td>145</td>
<td>variable</td>
<td>Compound: UL service flow</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>
11.1.5 Vendor ID encoding

The value field contains the vendor identification specified by the 3-byte, vendor-specific organizationally unique identifier of the SS or BS MAC address.

When used as a subfield of the TLVs Vendor-specific information, Vendor-specific QoS parameters, Vendor-specific classification rule parameters, Vendor-specific PHS parameters, or Software upgrade descriptors, the Vendor ID encoding identifies the Vendor ID of the SSs that are intended to use this information. A vendor ID used in a Registration Request shall be the Vendor ID of the SS sending the request. A vendor ID used in a Registration Response shall be the Vendor ID of the BS sending the response.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>144</td>
<td>3</td>
<td>v1, v2, v3</td>
<td>REG-REQ (see 6.3.2.3.7), REG-RSP (see 6.3.2.3.8)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>SBC-REQ (see 6.3.2.3.23) SBC-RSP (see 6.3.2.3.24)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSx-REQ, DSx-RSP, DSx-ACK, Configuration File</td>
</tr>
</tbody>
</table>

11.1.6 Vendor-specific information

Vendor-specific information for SSs, if present, shall be encoded in the vendor-specific information field (VSIF) (type 143) using the Vendor ID field (11.1.5) to specify which tuples apply to which vendor’s products. The Vendor ID shall be the first TLV embedded inside VSIF. If the first TLV inside VSIF is not a Vendor ID, then the TLV shall be discarded.

This configuration setting may appear multiple times. The same Vendor ID may appear multiple times. This configuration setting may be nested inside a Packet Classification Configuration Setting, a Service Flow Configuration Setting, or a Service Flow Response. However, there shall not be more than one Vendor ID TLV inside a single VSIF.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>143</td>
<td>variable</td>
<td>Per vendor definition</td>
<td>MAC Management message per vendor</td>
</tr>
</tbody>
</table>

Example: Configuration with vendor-A-specific fields and vendor-B-specific fields:

VSIF (143) + n (number of bytes inside this VSIF)
144 (Vendor ID Type) + 3 (length field) + Vendor ID of Vendor A
Vendor A Specific Type #1 + length of the field + Value #1
Vendor A Specific Type #2 + length of the field + Value #2

VSIF (143) + n (number of bytes inside this VSIF)
144 (Vendor ID Type) + 3 (length field) + Vendor ID of Vendor B
Vendor B Specific Type + length of the field + Value
11.1.7 Sleep mode specific information

11.1.7.1 Enabled-Action-Triggered

This value indicates the enabled action that MS performs upon reaching trigger condition in sleep mode. MS may include this TLV item in MOB_SLP-REQ message to request an activation of type of Power Saving Class. BS shall include this TLV in MOB_SLP-RSP message transmitted in response to the MOB_SLP-REQ message.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 139  | 1      | Indicates action performed upon reaching trigger condition in sleep mode  
|      |        | If bit 0 is set to 1, respond on trigger with MOB_SCN-REP          | MOB_SLP-REQ/RSP        |
|      |        | If bit 1 is set to 1, respond on trigger with MOB_MSHO-REQ         | RNG-REQ/RSP           |
|      |        | If bit 2 is set to 1, on trigger, MS starts neighboring BS scanning  |                        |
|      |        | process by sending MOB_SCN-REQ                                    |                        |
|      |        | Bit 3–bit 7: Reserved. Shall be set to 0.                         |                        |

11.1.7.2 SLPID_Update

The SLPID_Update TLV specifies a new SLPID that replaces an old SLPID. This TLV may include multiple Old_New_SLPID values for the MSs negatively indicated in MOB_TRF-IND message.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>138</td>
<td>variable</td>
<td>See following table</td>
<td>RNG-RSP, MOB_TRF-IND</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Length (bits)</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Old New SLPID</td>
<td>20</td>
<td>First 10 bits indicates old SLPID and the second 10 bits indicates new SLPID</td>
</tr>
</tbody>
</table>

11.1.7.3 Next Periodic Ranging

This value indicates the offset of the frame in which the periodic ranging will be performed with respect to the frame where MOB_SLP-RSP or RNG-RSP with ranging status = ‘success’ is transmitted. If MS receives MOB_SLP-RSP or RNG-RSP message with ‘Next Periodic Ranging’ = 0, it shall deactivate all active Power Saving Classes and return to Normal Operation.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>137</td>
<td>2</td>
<td>Offset in frames</td>
<td>MOB_SLP-RSP, RNG-RSP</td>
</tr>
</tbody>
</table>

11.1.8 Idle mode specific information

11.1.8.1 MAC Hash Skip Threshold

“MAC Hash Skip Threshold” indicates the maximum number of successive MOB_PAG-ADV messages without individual notification to the MS. If the value is 0xFF, the BS shall omit the MS MAC address hash of the MS with Action Code=0x00 in MOB_PAG-ADV messages. If the value is zero, the BS shall include the MS MAC address hash of the MS in every MOB_PAG-ADV message.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>136</td>
<td>1</td>
<td>0x00-0xFE: Initial value of the MAC Hash Skip Threshold Counter (refer to 6.3.23.6) 0xFF: This BS shall omit the MS MAC Address hash in MOB_PAG-ADV messages and MS does not start MAC Hash Skip Counter. (6.3.23.6 and 6.3.23.8.1.4)</td>
<td>RNG-REQ/RSP, DREG-REQ/CMD</td>
</tr>
</tbody>
</table>

11.1.8.2 Paging Controller ID

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>135</td>
<td>6</td>
<td>This is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in IDLE Mode.</td>
<td>RNG-REQ, RNG-RSP, DREG-CMD</td>
</tr>
</tbody>
</table>

11.1.8.3 Paging information

In case of RNG-RSP message, Paging Information shall be included if Location Update Response is set to 0x00 (Success of Idle Mode Location Update) and Paging Information has changed.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>134</td>
<td>7</td>
<td>Bits 0–15: PAGING_CYCLE—Cycle in which the paging message is transmitted within the paging group. Bits 16–31: PAGING_OFFSET—Determines the frame within the cycle from which the paging interval starts. Shall be smaller than PAGING_CYCLE value. Bits 32–47: Paging-group-ID—ID of the paging group to which the MS is assigned. Bits 48–55: Paging Interval Length—Max duration in frames of Paging Listening interval. Used in calculation of Paging listening interval; value shall be between 1 and 5 frames (default=2).</td>
<td>RNG-RSP, DREG-CMD</td>
</tr>
</tbody>
</table>

11.1.9 SA-TEK-Update

The “SA-TEK-Update” field provides a translation table that allows an MS to update its security associations and TEK pairs so that it may continue security service after a handover to a new serving BS.
The “SA-TEK-Update” field is a compound TLV list where each entry identifies the primary and static SAs, their SA identifiers (SAID) and additional properties of the SA (e.g., type, cryptographic suite) that the MS is authorized to access. In case of HO, the details of any Dynamic SAs that the requesting MS was authorized in the previous serving BS are also included.

Additionally, in case of HO, for each active SA in previous serving BS, corresponding TEK, GTEK, and GKEK parameters are also included. Thus, SA_TEK_Update provides a shorthand method for renewing active SAs used by the MS in its previous serving BS. The TLVs specify SAID in the target BS that shall replace active SAID used in the previous serving BS and also “older” TEK-Parameters and “newer” TEK Parameters relevant to the active SAIDs. The update may also include multicast/broadcast Group SAIDs (GSAIDs) and associated GTEK-Parameter pairs. The new SAID field shall refer to SAID assignments by the new BS. The mapping of these new SAIDs to the SAIDs assigned by the previous serving BS is controlled by the SAID Update TLV (11.7.17) and is further controlled by the rules for SAID updating outlined in 6.3.21.2.8.1.6.6.

In case of unicast SAs, the TEK-Parameters attribute contains all of the keying material corresponding to a particular generation of a SAID’s TEK. This would include the TEK, the TEK’s remaining key lifetime, its key sequence number, and the cipher block chaining (CBC) initialization vector. The TEKs are encrypted with KEK.

In case of group or multicast SAs, the TEK-Parameters attribute contains all of the keying material corresponding to a particular generation of a GSAID’s GTEK. This would include the newer GTEK parameter pairs, GTEK’s remaining key lifetime, the GTEK’s key sequence number, and the cipher block chaining (CBC) initialization vector. The type and length of the GTEK are equal to the ones of the TEK. The GKEK should be identically shared within the same multicast group or the broadcast group. The GTEKs are encrypted with GKEK and GKEKs are encrypted with KEK.

Multiple iterations of these TLVs may occur suitable to re-creating and reassigning all active SAs and their (G)TEK pairs for the MS from its previous serving BS. If any of the Security Associations parameters change, then those Security Associations parameters encoding TLVs that have changed will be added.

This TLV may be sent in a single frame along with unsolicited REG-RSP.

The following TLV values shall appear in each SA TEK Update TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (1 byte)</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>

</thead>
</table>
| SA-TEK-Update-Type | 142.1 | 1             | 1: TEK parameters for an SA
|                 |      |               | 2: GTEK parameters for a GSA
|                 |      |               | 3–255: Reserved                                |
| New SAID        | 142.2 | 2             | New SAID after handover to new BS               |
All sub-attributes included in the TEK-Parameters (Old TEK/GTEK-Parameters, New TEK/GTEK-Parameters and GKEK-Parameters are defined in 11.9.

11.1.10 NSP List encodings

11.1.10.1 NSP List

The NSP LIST TLV contains one or more 24-bit Network Service Provider Identifiers.

11.1.10.2 Verbose NSP Name List

The Verbose NSP Name List is a compound list of the verbose names of the Network Service Providers as indicated by the NSP List.
11.1.11 MIH message encodings

11.1.11.1 MIHF frame

This TLV is used to carry an MIHF frame. MIHF frames are specified in IEEE Std 802.21.

<table>
<thead>
<tr>
<th>Field</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verbose NSP Name Length</td>

</tbody>
</table>

11.1.12 MCID Update Management encoding

The TLV encodings defined in this subclause are specific to the MBS_MAP (6.3.2.3.52) and MOB_NBR-ADV (6.3.2.3.42) MAC management message. These TLVs provide information regarding several MBS zones and the MCID used in them.

11.1.12.1 MCID pre-allocation and transmission info

This TLV indicates the mapping of MCIDs used in the current MBS Zone ID to new MCID within a neighboring MBS zone and information regarding the MBS map transmission in the neighboring MBS zone.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length (bytes)</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>128</td>
<td>variable (3 + N × 4)</td>
<td>See Table 566</td>
<td>MBS_MAP, MOB_NBR-ADV</td>
</tr>
</tbody>
</table>

Table 566—MCID Pre-allocation and Transmission Info definition

<table>
<thead>
<tr>
<th>Field</th>
<th>Length (bits)</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBS_ZONE_ID</td>

</tr>
<tr>
<td>Neighboring_MBS_ZONE_ID</td>
<td>7</td>
<td>MBS zone identifier for neighboring MBS Zone</td>
</tr>
<tr>
<td>Neighboring zone type</td>
<td>1</td>
<td>0 – Neighbor MBS zone supports macro-diversity 1 – Neighbor MBS zone does not support macro-diversity</td>
</tr>
<tr>
<td>Next_MBS_Frame_Offset_Delta</td>
<td>4</td>
<td>Signed integer: −8 to +7. This value is added to the Next_MBS_Frame_Offset in MBS_DATA_IE, Extended_MBS_DATA_IE, or MBS_DATA_Time_Diversity_IE to obtain the frame offset to the next MBS MAP message in the neighboring MBS Zone. The range of this value is −7 to 7 frames. The value of −8 indicates that there is no indication regarding the transmission in the neighboring zone.</td>
</tr>
</tbody>
</table>

Copyright © 2009 IEEE. All rights reserved.
A value of 0xFFFF in the New_MCID field indicates that the service flow corresponding to Current_MCID is not available in the MBS Zone indicated by the TLV.

To receive the MBS MAP in the neighboring MBS zone, the MS is required to receive the MBS_MAP_IE in the DL MAP in the neighboring MBS zone. This is performed using the information in the “Next MBS frame offset” field in the MBS data allocation IE (i.e., MBS_DATA_IE, Extended_MBS_DATA_IE, and MBS_DATA_Time_Diversity_IE) and the Next_MBS_Frame_Offset_Delta field in the TLV. The MBS_MAP_IE is located in the frame offset indicated by the sum of the two fields (Next MBS frame offset field in the MBS data allocation IE and Next_MBS_Frame_Offset_Delta field in the TLV).

### 11.1.12.2 MCID Continuity and Transmission Info

This field indicates a certain MCID stays the same in one or more MBS Zones and information regarding the MBS map transmission in the neighboring MBS zone.

<table>
<thead>
<tr>

<td>1</td>
<td>0 – Neighbor MBS zone supports macro-diversity</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 – Neighbor MBS zone does not support macro-diversity</td>
</tr>
</tbody>
</table>
To receive the MBS MAP in the neighboring MBS zone, the MS is required to receive the MBS_MAP_IE in the DL MAP in the neighboring MBS zone. This is performed using the information in the “Next MBS frame offset” field in the MBS data allocation IE (i.e., MBS_DATA_IE, Extended_MBS_DATA_IE, and MBS_DATA_Time_Diversity_IE) and the Next_MBS_Frame_Offset_Delta field in the TLV. The MBS_MAP_IE is located in the frame offset indicated by the sum of the two fields (Next MBS frame offset field in the MBS data allocation IE and Next_MBS_Frame_Offset_Delta field in the TLV).

If there are no MCIDs listed in this TLV and “No MCID Update Info Present” field is set to zero then all MCIDs within the current MBS Zone stay the same in the neighboring MBS Zone indicated by the TLV and the “Next_MBS_Frame_Offset_Delta” applies to all MCIDs.

### 11.2 Configuration file encodings

These settings are found only in the configuration file. They shall not be forwarded to the BS in the Registration Request.

<table>
<thead>
<tr>

To receive the MBS MAP in the neighboring MBS zone, the MS is required to receive the MBS_MAP_IE in the DL MAP in the neighboring MBS zone. This is performed using the information in the “Next MBS frame offset” field in the MBS data allocation IE (i.e., MBS_DATA_IE, Extended_MBS_DATA_IE, and MBS_DATA_Time_Diversity_IE) and the Next_MBS_Frame_Offset_Delta field in the TLV. The MBS_MAP_IE is located in the frame offset indicated by the sum of the two fields (Next MBS frame offset field in the MBS data allocation IE and Next_MBS_Frame_Offset_Delta field in the TLV).

If there are no MCIDs listed in this TLV and “No MCID Update Info Present” field is set to zero then all MCIDs within the current MBS Zone stay the same in the neighboring MBS Zone indicated by the TLV and the “Next_MBS_Frame_Offset_Delta” applies to all MCIDs.

### 11.2 Configuration file encodings

These settings are found only in the configuration file. They shall not be forwarded to the BS in the Registration Request.
11.2.1 SS MIC configuration setting

This value field contains the SS MIC code. This is used to detect unauthorized modification or corruption of the configuration file.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>20</td>
<td>d1 d2... d20</td>
</tr>
</tbody>
</table>

11.2.2 Software upgrade descriptors

This field defines the parameters associated with software upgrades. It is composed of one or more upgrade descriptors. An upgrade descriptor is defined by the set of all encapsulated tags defined in 11.2.2.1 through 11.2.2.4, occurring in order in the TFTP file. A new upgrade descriptor begins with the occurrence of the Vendor ID TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Variable</td>
<td>Compound</td>
</tr>
</tbody>
</table>

When a managed SS decodes a descriptor with a matching Vendor ID, Hardware ID, and Software version different than the one currently running, it may initiate a TFTP transfer to upgrade its software.

11.2.2.1 Vendor ID

This value identifies the managed SS vendor to which the software upgrade is to be applied. Its format and value is described in 11.1.5.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.144</td>
<td>3</td>
<td>v1, v2, v3</td>
</tr>
</tbody>
</table>

11.2.2.2 Hardware ID

This value identifies the hardware version to which the software upgrade is to be applied. This value is administered by the vendor identified by the Vendor ID field.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.1</td>
<td>n</td>
<td>Hardware ID (string)</td>
</tr>
</tbody>
</table>
11.2.2.3 Software version

This value identifies the software version of the software upgrade file. The value is administered by the vendor identified in the Vendor ID field. It should be defined by the vendor to be unique with respect to a given Hardware ID.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.2</td>
<td>n</td>
<td>Software version (string)</td>
</tr>
</tbody>
</table>

11.2.2.4 Upgrade filename

The filename of the software upgrade file for the managed SS. The filename is a fully qualified directory-path name that is in a format appropriate to the server. There is no requirement that the character string be null-terminated; the length field always identifies the end of the string. The file is expected to reside on a TFTP server identified in a configuration setting option defined in 11.2.3.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.3</td>
<td>n</td>
<td>Filename</td>
</tr>
</tbody>
</table>

11.2.3 Software upgrade TFTP server

This object is the IP address of the TFTP server on which the software upgrade file for the SS resides.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4 or 16</td>
<td>IP Address</td>
</tr>
</tbody>
</table>

11.2.4 TFTP Server Timestamp

This is the sending time of the configuration file in seconds. The definition of time is as in IETF RFC 868.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>4</td>
<td>Number of seconds since 00:00 1 January 1900</td>
</tr>
</tbody>
</table>

NOTE—The purpose of this parameter is to prevent replay attacks with old configuration files.

11.2.5 MIB object write-access control

SS support of MIB object write-access control is recommended. This object makes it possible for an operator to disable SNMP “Set” access to individual Management Information Base (MIB) objects while a SS is connected to that operator network. This behavior is not persistent and terminates when the SS deregisters or loses connection to the BS. Each instance of this object controls access to all of the writable...
MIB objects whose Object ID (OID) prefix matches. The object may be repeated to disable access to any number of MIB objects, where, n is the size of the ASN.1 Basic Encoding Rules [ISO 8825] encoding of the OID prefix plus one byte for the control flag.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>n</td>
<td>OID prefix plus control flag</td>
</tr>
</tbody>
</table>

The control flag may take the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>allow write-access</td>
</tr>
<tr>
<td>1</td>
<td>disallow write-access</td>
</tr>
</tbody>
</table>

Any OID prefix may be used. The Null OID 0.0 may be used to control access to all MIB objects with MAX-ACCESS as writable.

When multiple instances of this object are present and overlap, the longest (most specific) prefix has precedence. Thus, one example might be as follows:

<table>
<thead>
<tr>
<th>someTable</th>
<th>disallow write-access</th>
</tr>
</thead>
<tbody>
<tr>
<td>someTable.1.3</td>
<td>allow write-access</td>
</tr>
</tbody>
</table>

This example disallows MAX-ACCESS write-access to all writable objects in someTable except for someTable.1.3.

An attempt to set the MAX-ACCESS write-access of an unsupported MIB element or prefix shall be silently discarded.

### 11.2.6 Set MIB Object

This object allows arbitrary MIB objects to be Set via the TFTP configuration file, where the value is an ASN.1 VarBind as defined in IETF RFC 1157. The VarBind is encoded in ASN.1 Basic Encoding Rules (just as it would be if part of an SNMP Set request, for example).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>n</td>
<td>variable binding</td>
</tr>
</tbody>
</table>

SS support of Set MIB Object is recommended, but is not required. The SS shall treat this object as if it were part of an “Set” Request for the applicable MIB variable with the following caveats:
a) It shall treat the request as fully authorized (it shall not refuse the request for lack of privilege).

b) Attempt to write to MAX-ACCESS read-only MIB variables will be disallowed and silently discarded. Temporary MAX-ACCESS write restriction due to application of MIB object write-access control 11.2.5 shall not be considered when evaluating attempt to write to MIB objects for this purpose.

c) Writes to persistent MIB variables shall only update the “working” copy. A MIB value that supports persistence shall not update its nonvolatile store for the indicated MIB object; such updates are only supported when the SS is connected and registered to the BS.

This object may be repeated with different VarBinds to “Set” a number of MIB objects. All such Sets shall be treated as if simultaneous.

Each VarBind shall be limited to 255 bytes.

**11.3 UCD management message encodings**

The UCD message encodings are specific to the UCD message (see 6.3.2.3.3).

**11.3.1 UCD channel encodings**

UCD channel encodings shared across PHY specifications are provided in Table 568.

For FDD/H-FDD operation, if two TLVs for a particular type occur in the UCD, the first TLV corresponds to H-FDD group 1, while the second TLV corresponds to H-FDD group 2.

<table>
<thead>
<tr>

| UL PUSC Subchannel Rotation               | 203           | 1      | Value: Indicates the default setting of subchannel rotation in the UL frame.  
Value 0 (default) indicates UL PUSC subchannel rotation is enabled.  
Value 1 indicates UL PUSC subchannel rotation is disabled.  
The default setting of subchannel rotation is only valid in zones that are not preceded by an OFDMA uplink Zone IE. If this TLV is not present, the default setting of UL PUSC subchannel rotation is enabled. |
| Relative Power Offset for UL HARQ burst   | 205           | 1      | Bits 0–3: Offset for HARQ burst relative to non-HARQ burst (signed integer in 0.5 dB unit)  
Bits 4–7: reserved (Shall be set to zero)  
If this TLV is not present, the default value of power offset shall be equal to zero. |
| Relative Power Offset for UL Burst Containing MAC Management Message | 206           | 1      | Bits 0–2: Power offset for UL burst containing a MAC management message relative to the normal traffic burst (unsigned integer in 0.5 dB units).  
Bits 3–7: reserved (Shall be set to zero).  
If this TLV is not present, the default value of the power offset shall be equal to zero. |
| UL_initial_transmit_timing                | 207           | 1      | 0 b00000000 : The timing is referenced to the ‘UL_Allocation_Start_Time’  
0 b00000001 - 0 b11111110 : Timing offset in unit of 2 PSs (two physical slots) before ‘UL_Allocation_Start_Time’ to which the MS timing shall be referenced. If this value is larger than ‘TTG-SSRTG’, then MS shall consider this value as ‘TTG-SSRTG’. For example, 0 b00000001 means ‘initial timing reference = UL_Allocation_Start_Time – 2 PSs’  
0 b11111111 : The timing is referenced to the ‘UL_Allocation_Start_Time-TTG+SSRTG’. If this TLV is not present, the default value of initial timing at MS shall be ‘UL_Allocation_Start_Time’ |
| UL PHY Mode ID                            | 208           | 2      | Bits 0–7: Channel bandwidth in units of 125 kHz;  
Bits 8–10: FFT size  
0 b000= 2048  
0 b001= 1024  
0 b010=512  
0 b011=128  
0 b100 – 0 b111: reserved  
Bits 11–13: Cycle Prefix (CP)  
0 b000= 1/4  
0 b001= 1/8  
0 b010=1/16  
0 b011=1/32  
0 b100 – 0 b111: reserved  
Bits 14–15: reserved  
NOTE—This TLV shall only be used for FDD operation. This TLV shall be included only if the UL channel bandwidth is different from the DL channel bandwidth. When this TLV is part of the compound UCD_settings TLV (11.18.1), the PHY Mode ID (11.18.2) applies to the DL only |

|                                |               |        | Bits 35–39, Allocation phase expressed in frames, 0 ≤ Allocation Phase < periodicity (=2<sup>d</sup>)  
|                                |               |        | NOTE—Up to two TLVs may be used for FDD/H-FDD, to indicate two fast feedback regions in two groups. |
| HARQ Ack Region                | 211           | 4      | Bits 0–3: num subchannels  
|                                |               |        | Bits 4–8: No. OFDMA symbols  
|                                |               |        | Bits 9–15: Subchannel offset  
|                                |               |        | Bits 16–23: OFDMA Symbol offset  
|                                |               |        | Bits 24–26, Parameter d that defines periodicity of 2<sup>d</sup> frames  
|                                |               |        | Bits 27–31, Allocation phase expressed in frames, 0 ≤ Allocation Phase < periodicity (=2<sup>d</sup>)  
|                                |               |        | NOTE—Up to two TLVs may be used for FDD/H-FDD, see 8.4.5.4.23. |
| Ranging Region                 | 212           | 5/10/15/20 | The value of TLV consists of up to four concatenated sections (one section per Ranging method), each having the following structure:  
|                                |               |        | Bit 0: dedicated ranging indicator  
|                                |               |        | Bits 1–2: ranging method  
|                                |               |        | Bits 3–9: num subchannels  
|                                |               |        | Bits 10–16: num OFDMA symbols  
|                                |               |        | Bits 17–23: subchannel offset  
|                                |               |        | Bits 24–31: OFDMA symbol offset  
|                                |               |        | Bits 32–34, Parameter d that defines periodicity of 2<sup>d</sup> frames  
|                                |               |        | Bits 35–39, Allocation phase expressed in frames, 0 ≤ Allocation Phase < periodicity (=2<sup>d</sup>)  
| Sounding Region                | 213           | 5/10   | For 5 bytes per each sounding region  
|                                |               |        | Bit 0: reserved  
|                                |               |        | Bits 1–2: PAPR Reduction/Safety zone  
|                                |               |        | Bits 3–9: num subchannels  
|                                |               |        | Bits 10–16: num OFDMA symbols  
|                                |               |        | Bits 17–23: subchannel offset  
|                                |               |        | Bits 24–31: OFDMA symbol offset  
|                                |               |        | Bits 32–34, Parameter d that defines periodicity of 2<sup>d</sup> frames  
|                                |               |        | Bits 35–39, Allocation phase expressed in frames, 0 ≤ Allocation Phase < periodicity (=2<sup>d</sup>)  
| MS Transmit Power Limitation Level | 214          | 1      | Unsigned 8-bit integer. Specifies the maximum allowed MS transmit power. Values indicate power levels in 1 dB steps starting from 0 dBm.  
| H-FDD Group Switch Delay       | 215           | 1      | The delay (in frames) of H-FDD Group Switching transition; in accordance with 8.4.4.2.1. If this parameter is not present, H-FDD Group Switching Delay shall default to H-ARQ ACK Delay.  
|                                |               |        | For H-FDD, either H-FDD Group Switch Delay or H-ARQ ACK Delay shall be present in the UCD. |

11.4.1 DCD channel encodings

The DCD Channel Encodings are provided in Table 575.

For FDD/H-FDD operation, if two TLVs for a particular type occur in the DCD, the first TLV corresponds to H-FDD group 1, while the second TLV corresponds to H-FDD group 2.

### Table 575—DCD channel encodings

| Cell Type TLV                     | 57            | 1      | Cell type TLV may be used by the MS in the network for cell selection and reselection. Cell Type is encoded as follows: Bits 0–3: Indicates class of BS  
  a) if bits 0–3 = 0000, it is a class-0 BS  
  b) if bits 0–3 = 0001, it is a class-1 BS  
  c) if bits 0–3 = 0010, it is a class-2 BS  
  d) if bits 0–3 = 0011, it is a class-3 BS  
  e) if bits 0–3 = 0100, it is a class-4 BS  
  f) if bits 0–3 = 0101, it is a class-5 BS  
  g) if bits 0–3 = 0110, it is a class-6 BS  
  h) if bits 0–3 = 0111, it is a class-7 BS  
  i) if bits 0–3 = 1000, it is a class-8 BS  
  j) if bits 0–3 = 1001, it is a class-9 BS  
  k) if bits 0–3 = 1010, it is a class-10 BS  
  l) if bits 0–3 = 1011, it is a class-11 BS  
  m) if bits 0–3 = 1100, it is a class-12 BS  
  n) if bits 0–3 = 1101, it is a class-13 BS  
  o) if bits 0–3 = 1110, it is a class-14 BS  
  p) if bits 0–3 = 1111, it is a class-15 BS  
  The definition of these classes are out of scope of the specification  
  Bits 4–7 of the cell Type are reserved. | All       |
| \( N + I \)                       | 60            | 1      | The operator will define the \( N + I \) (Noise + Interference) based on the related RF system design calculations. | OFDM      |
| MBS zone identifier list          | 61            | variable | This parameter shall include all MBS zone identifiers (i.e., \( n \times \text{MBS zone identifier} \)) with which BS is associated. An MBS zone identifier is 1 byte long. Bits 6 through 0 are the MBS Zone Identifier, bit 7 is set to 0 in each byte.  
  The MBS Zone identifier shall not be ‘0’. When the parameter is part of a compound DCD_settings TLV (refer to 11.18.1), a value of 0 means that the neighbor BS is not affiliated with any MBS zone | All       |

<td></td>
<td>NOTE 2—When type 0x1 is used together with function 0x3 or 0x4, the threshold value shall range from –32 dB (0x80) to +31.75 dB (0x7F). When type 0x1 is used together with function 0x5 or 0x6, the threshold value shall be interpreted as an unsigned byte with units of 0.25 dB, such that 0x00 is interpreted as –103.75 dBm and 0xFF is interpreted as –40 dBm</td>
</tr>
</tbody>
</table>

If Trigger TLVs are included in the DCD message, the MS may ignore Trigger TLVs having a metric that the MS and BS have not agreed to support during SBC-REQ/RSP message exchange.

When the average value of the MS’s measurements over the averaging interval of a trigger defined by a Trigger TLV meets the trigger condition as specified by the type, function, and value of the trigger, the MS shall invoke the trigger’s specified action. For the metrics CINR and RSSI, the average values are computed using the formulae defined in 8.4.12. Whenever the trigger condition of a trigger is met, the MS shall invoke the action of the trigger. If more than one trigger conditions are met simultaneously the MS shall invoke the action of at least one of the triggers.
Triggers specified in this TLV may be overridden by triggers specified in the Neighbor BS Trigger TLV (see 6.3.2.3.42, Table 145).

The set of triggers defined by the Trigger TLVs in the DCD_settings compound TLV for a given neighbor BS shall be identical to the complete set of triggers in the DCD message of that BS. When this TLV does not occur in the DCD_settings compound TLV for a given neighbor BS, the set of Trigger TLVs in the neighbor BS's DCD message shall be identical to the set of Trigger TLVs in the current BS.

The CINR, RSSI, and RTD metric fields are encoded according to the descriptions found within 6.3.2.3.45 for the MOB_SCN-REP message and 6.3.2.3.48 for the MOB_MSHO-REQ message.

The RTD trigger shall be measured only on the serving BS rather than relative to or from neighbor BSs. The trigger functions 0x5 and 0x6 shall be the only applicable ones for the RTD trigger. When the type is set to RTD metric (i.e., 0x2), only either of the trigger functions 0x5 or 0x6 shall be applicable.

The MS may transmit MOB_MSHO-REQ and MOB_SCN-REQ messages autonomously, i.e., in addition to messages prompted by trigger conditions.

11.6 RNG-RSP management message encodings

CID update encodings (11.7.9) and SAID update encodings (11.7.17) may be used in RNG-RSP for reestablishing connections. When CID update encodings or SAID update encodings are used in RNG-RSP, those will be included in the compound REG-RSP encodings TLV. When the compound SBC-RSP encodings and REG-RSP encodings are included in RNG-RSP for HO optimization, the target BS shall only include TLV fields which values are different from what are used in the serving BS. For the TLV fields that are not included in the compound SBC-RSP and REG-RSP encodings, the MS shall set the values according to what are used in the serving BS. The encodings in Table 585 are specific to the RNG-RSP message (6.3.2.3.6).

<td>1</td>
<td>Indicates whether the former serving BS retains the connection information of the MS: 0 = Connection information for the MS is deleted. 1 = Connection information for the MS is retained.</td>
<td>All</td>
</tr>
</tbody>
</table>
For each Bit location, a value of ‘0’ indicates the associated re-entry management messages shall be required, a value of ‘1’ indicates the re-entry management message should be omitted.

**Bit 0:** Omit SBC-REQ management messages during current re-entry processing.

- (Bit 1, Bit 2) = (0,0): Perform re-authentication and SA-TEK 3-way handshake. BS shall not include SA-TEK-Update TLV in the SA-TEK-Response message. In addition, the RNG-RSP message does not include SA-TEK-Update TLV.
- (Bit 1, Bit 2) = (0,1): Reserved.
- (Bit 1, Bit 2) = (1,0): SA-TEK-Update TLV is included in the RNG-RSP message. In this case, SA-TEK 3-way handshake is avoided.
- (Bit 1, Bit 2) = (1, 1): Re-authentication and SA-TEK 3-way handshake is not performed. The RNG-RSP message does not include SA-TEK-Update TLV. All the TEKs received from the serving BS are reused.

**Bit 3:** Omit Network Address Acquisition management messages during current reentry processing

**Bit 4:** Omit Time of Day Acquisition management messages during current reentry processing

**Bit 5:** Omit TFTP management messages during current re-entry processing

**Bit 6:** If Bit 6 = 1, Full service and operational state transfer or sharing between Serving BS and Target BS (All static and dynamic context, e.g., ARQ windows, timers counters state machines)

**Bit 7:** Omit REG-REQ management message during current re-entry processing

**Bit 8:** If Bit 8 = 0, BS shall send an unsolicited SBC-RSP management message

**Bit 9:** If Bit 9 = 1, post-HO re-entry MS DL data pending at target BS

**Bit 10:** If Bit 10 = 0, BS shall send an unsolicited REG-RSP management message

**Bit 11:** (Target) BS supports virtual SDU SN. If Bit 11=1 and MS supports SDU SN, it shall issue SN REPORT upon completion of HO to this BS.

**Bit 12:** If Bit 12 = 1, MS shall send a notification of MS’s successful re-entry registration.

**Bit 13:** If this bit is set to 1, MS shall trigger a higher layer protocol required to refresh its traffic IP address (e.g., DHCP Discover [IETF RFC 2131] or Mobile IPv4 re-registration [IETF RFC 3344]).

**Bits 14–15:** Reserved

### 11.7.1 ARQ Parameters

This field provides the fragmentation and ARQ parameters applied during the establishment of the secondary management connection. For purposes of ARQ parameter negotiation, the appearance of the field
in the REG-REQ message is equivalent to its appearance in the DSA-REQ message. The appearance of the
field in the REG-RSP message is equivalent to its appearance in the DSA-RSP message.

This field is a compound TLV that may take on any of the ARQ parameters described in 11.13.17. The
subtype values defined for use within the 145/146 service flow definitions are applicable for this TLV as
well.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>variable</td>
<td>Compound</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

### 11.7.2 SS management support

This field indicates whether the SS is managed by standard-based IP messages over the secondary
management connection. When the SS indicates in the REG-REQ that it is managed, the BS shall respond
with this field in the REG-RSP message to indicate if the BS supports SS management. If BS also supports
SS management, the BS and SS shall perform stages g), h), and i) of the initial network entry process (see
6.3.9). Otherwise, if the BS or the SS does not support SS management, these stages shall be skipped by the
BS and SS. If this TLV is not included in REG-REQ and REG-RSP message, it means that SS has no
secondary management connection.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>0 = No secondary management connection (default)</td>
<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Secondary management connection</td>
<td></td>
</tr>
</tbody>
</table>

### 11.7.3 IP management mode

The IP management mode parameter dictates whether the provider intends to manage the SS on an ongoing
basis via IP-based mechanisms. If this TLV is not included in REG-REQ and REG-RSP message, it means
that SS is the unmanaged mode.

<table>
<thead>
<tr>

</table>
11.7.5 Secondary Management CID

This parameter contains the Secondary Management CID issued to an SS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
<td>Secondary Management CID</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>

11.7.6 Number of CIDs supported

11.7.6.1 Number of Uplink Transport CIDs Supported field

This field shows the number of UL transport CIDs the SS can support.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>2</td>
<td>Number of UL Transport CIDs the SS can support.</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.6.2 Number of Downlink Transport CIDs Supported field

This field shows the number of DL transport CIDs the SS can support.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>2</td>
<td>Number of DL Transport CIDs the SS can support.</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.7 CS capabilities

11.7.7.1 Classification/PHS options and SDU encapsulation support

This parameter indicates which classification/PHS options and SDU encapsulation the SS supports. By default, Packet, IPv4 and IEEE 802.3/Ethernet shall be supported, thus absence of this parameter in REG-REQ means that named options are supported by the SS. When the length field of the TLV is 2, it indicates that bits 16–31 should be considered to be equal to zero.
### 11.7.7.2 Maximum number of classification rules

This is the maximum number of admitted classification rules that the SS supports.

<table>
<thead>
<tr>

<td></td>
<td>Bit 2: GPCS PHS</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3–7: Reserved; shall be set to zero</td>
<td></td>
</tr>
</tbody>
</table>

A bit value of 1 indicates the associated PHS feature is supported.

The default value is 0 (no PHS).

11.7.7.4 ROHC support

This parameter is used by the SS or BS to indicate support for ROHC.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>1</td>

<td>2–255: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

11.7.8.2 DSx flow control

This field specifies the maximum number of concurrent DSA, DSC, or DSD transactions that may be outstanding. An SS shall maintain only one outstanding DSA, DSC or DSD transaction for any service flow.
11.7.8.3 MCA flow control

This field specifies the maximum number of concurrent MCA transactions that may be outstanding.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>1</td>
<td>0 indicates no limit (default) 1–255 indicate maximum concurrent transactions</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.8.4 Multicast polling group CID support

This field indicates the maximum number of simultaneous multicast polling groups to which the SS is capable of belonging.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>1</td>
<td>0–255 Default = 0</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.8.5 Maximum MAC data per frame support

This compound TLV defines the maximum amount of MAC level data including MAC headers and HARQ retransmission bursts the MS is capable of processing in the DL/UL part of a single MAC frame. A value of 0 indicates such limitation does not exist, except the limitation of the physical medium. If those TLVs are absent then the default value (0) should be used.

<table>
<thead>
<tr>
<th>Name</th>

<tr>
<td></td>
<td></td>
<td>1: Packing supported</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>2–255: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

11.7.8.7 MAC Extended rtPS support

The MAC Extended rtPS Support field indicates the availability of SS support for extended rtPS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>22</td>
<td>1</td>
<td>0 = No Extended rtPS support (default)</td>
<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Extended rtPS support</td>
<td></td>
</tr>
</tbody>
</table>

11.7.8.8 Maximum number of bursts transmitted concurrently to the MS

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Length (1 byte)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>Max_Num_Bursts</td>
<td>1</td>
<td>Valid values: 1–16 Maximum number of bursts transmitted concurrently to the MS. Includes all bursts without CID or with CIDs matching then MS's CIDs.</td>
</tr>
</tbody>
</table>

**11.7.8.9 Co-located coexistence capability supported**

The Co-located Coexistence Capability Supported TLV indicates if co-located coexistence is supported. MSs and BSs that support co-located coexistence shall identify themselves by including this TLV. For each bit, a value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 50   | 1      | Bit 0: PSC-based co-located coexistence mode 1  
      |        | Bit 1: PSC-based co-located coexistence mode 2  
      |        | Bit 2: Sleep mode follows the MAP relevance for PSC-based co-located coexistence  
      |        | Bit 3: Uplink band AMC for PSC-based co-located coexistence  
      |        | Bit 4–7: Reserved                  | REG-REQ, REG-RSP |

**11.7.8.10 H-FDD sleep capabilities**

H-FDD sleep capabilities TLV indicates if sleep mode is supported in HFDD mode. For each bit, a value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 51   | 1      | Bit 0: Support for sleep mode following MAP relevance for H-FDD  
      |        | Bits 1–7: Reserved                       | REG-REQ, REG-RSP |

**11.7.8.11 Extended capability**

The extended capability field specifies extended capability support for the specified features. For each bit, a value of 0 indicates “not supported” while 1 indicates “supported.” If the TLV is not transmitted, the default value of each mentioned capability is “not supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 49   | 1      | Bit 0: Indicates the capability to support ARQ Map Last Bit concept and the optimized Sequence Block as defined in Table 170. The feature is enabled only in case both MS and BS support it.  
      |        | Bit 1: Indicates the capability to support BS_Controlled_HO (see 6.3.21.2.2). If the MS does not support this capability, it may ignore the BS_Controlled_HO flag in the DCD.  
      |        | Bit 2: Indicates support for Group parameter Create/Change TLV (11.13.39)  
      |        | Bits 3–7: Reserved, set to zero                  | REG-REQ, REG-RSP |
11.7.9 CID Update Encodings field

The CID Update Encodings field provides a translation table that allows an MS to update its service flow and connection information so that it may continue service after an HO to a new serving BS.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type (1 byte)</th>
<th>Length (1 byte)</th>
<th>Value (variable length)</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>CID_update</td>
<td>24</td>
<td>variable</td>
<td>Compound</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>

These TLV values shall appear in each CID Update TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type (1 byte)</th>
<th>Length (1 byte)</th>
<th>Value (variable length)</th>
</tr>
</thead>
<tbody>
<tr>
<td>New_CID</td>
<td>24.1</td>
<td>2</td>
<td>New CID after HO to new BS.</td>
</tr>
<tr>
<td>SFID</td>
<td>24.2</td>
<td>4</td>
<td>Service flow ID</td>
</tr>
</tbody>
</table>

The following TLV element may appear in a CID Update TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type (1 byte)</th>
<th>Length (1 byte)</th>
<th>Value (variable length)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Info</td>
<td>24.3</td>
<td>variable</td>
<td>If any of the service flow parameters change, then those service flow parameter encoding TLVs that have changed will be added. Connection Info is a compound TLV value that encapsulates the service flow parameters that have changed for the service. All the rules and settings that apply to the parameters when used in the DSC-RSP message apply to the contents encapsulated in this TLV.</td>
</tr>
</tbody>
</table>

11.7.9.1 Compressed CID Update Encodings field

The Compressed CID Update Encodings field provides a translation table that allows an MS to update its CID. Only CIDs that have no parameter change can be translated by this TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compressed CID update</td>
<td>25</td>
<td>variable</td>
<td>The first byte indicates the length of the following BITMAP in bytes. The n-th bit, starting from the MSB of the BITMAP is set to 1 when the n-th SFID is to be updated to a new CID. Where, the SFIDs are sorted with increasing order. After the BITMAP, a list of new CID follows. The number of new CID is equal to the number of ones in the BITMAP.</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>
11.7.10 Method for allocating IP address for the secondary management connection

<table>

<td></td>
</tr>
</tbody>
</table>

11.7.11 Reserved

11.7.12 HO Support

11.7.12.1 System Resource_Retain_Time

The Resource_Retain_Time is the duration for MS’s connection information that will be retained in serving BS. BS shall start Resource_Retain_Time timer at MS notification of pending HO attempt through MOB_HO-IND or by detecting an MS drop. The unit of this value is 100 ms.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>2</td>
<td>0–65535: In units of 100 milliseconds</td>
<td>REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>300 (30 000 ms) is the default</td>
<td></td>
</tr>
</tbody>
</table>

11.7.12.2 HO Process Optimization MS Timer

During network reentry, the HO Process Optimization MS Timer is the duration in frames the MS shall wait until receipt of the next unsolicited network reentry MAC management message as indicated in the HO Process Optimization element of the RNG-RSP message. MS shall start HO Process Optimization MS Timer on receipt of RNG-RSP with HO Process Optimization message element indicating one or more unsolicited network reentry MAC management messages are pending and required to complete network reentry and establish MS Normal Operation with target BS. HO Process Optimization MS Timer shall recycle on MS receipt of any unsolicited network reentry MAC management message and shall terminate on MS establishment of Normal Operation with the target BS. On HO Process Optimization MS Timer timeout and while HO Process Optimization MS Timer Retries is valid, MS shall send the network reentry MAC management request message corresponding to the expected and pending network reentry MAC management response message as indicated in HO Process Optimization and recycle HO Process Optimization MS Timer.

<table>
<thead>
<tr>
<th>Type</th>

<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 7: Reserved, shall be set to zero</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.12.6 Handover indication readiness timer

During HO preparation phase, after transmitting the MOB_BSHO-REQ or the MOB_BSHO-RSP messages, the serving BS may allocate an unsolicited UL grant to enable MS to transmit MOB-HO-IND without issuing BW request.
During initial network entry, MS may transmit REG-REQ with Handover Indication Readiness Timer TLV, which is used to declare the minimum time it may require to process MOB_BSHO-REQ or MOB_BSHO- RSP messages.

The BS shall respond in REG-RSP with Handover Indication Readiness Timer TLV. The value included in REG-RSP shall be the greater of the MS supported value and the BS supported value (The BS value is the minimum time required to allocate an unsolicited UL grant. Handover Indication Readiness Timer is relative to the frame in which MOB_BSHO-REQ/RSP message is transmitted.

A value of 1 means the HO indication may be sent in the frame succeeding MOB_BSHO-REQ/RSP.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>46</td>
<td>1</td>
<td>In frames, Default = 2</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.12.7 BS switching timer

The serving BS uses Handover Indication Readiness Timer (11.7.12.6) and BS Switching Timer to determine Action Time in MOB_BSHO-REQ/RSP messages.

BS Switching Timer is the minimum time the MS requires between transmission of MOB_HO-IND message at the serving BS, until it is able to receive Fast_Ranging_IE at the target BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>47</td>
<td>1 or 2</td>
<td>Minimum time from transmission of MOB_HO-IND at the serving BS until proper reception of Fast_Ranging_IE at the target BS [in frames, minimum value is 1] Bits 0–3: minimum time for intra-FA HO default = 2 Bits 4–7: minimum time for inter-FA HO default = 3 Bits 8–15: minimum time for inter-FFT HO; 0xFF = coordinated handover not supported when FFT changes; default = 0xFF</td>
<td>REG-REQ</td>
</tr>
</tbody>
</table>

NOTE—Bits 8–15 shall only be sent if length = 2.

11.7.13 Mobility parameters support

The parameters in 11.7.13.1 are associated with mobile operations.

11.7.13.1 Mobility features supported

The Mobility Features Supported field indicates whether the MS supports mobility HO, sleep mode, and idle mode. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>1</td>
<td>Bit 0: Mobility (HO) support Bit 1: Sleep mode support Bit 2: Idle mode support</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>
11.7.13.2 Power saving class capability

For MS supporting sleep mode, this parameter defines the capability of the MS supporting power saving class in sleep mode.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 48   | 2      | Bit 0: Power saving class type I supported  
Bit 1: Power saving class type II supported  
Bit 2: Power saving class type III supported  
Bit 3: Multiple active power saving classes supported  
Bits 4–9: Total number of power saving class instances of all types supported by the MS  
Bits 10–15: Reserved | REG-REQ  
REG-RSP |}

11.7.14 Sleep mode recovery time

The Sleep Mode Recovery Time field indicates the time required for an MS that is in a sleep mode to return to awake mode. This parameter is optional and may be used by the BS to determine sleep interval window sizes when initiating sleep mode with an MS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 32   | 1      | Number of frames required for the MS to switch from sleep mode to awake mode. | REG-REQ |}

11.7.15 MS-PREV-IP-ADDR

The MS-PREV-IP-ADDR parameter specifies the IP address that the MS was assigned on the secondary management connection based on an association with its last serving BS. An IPv4 address shall be specified in conventional dotted format, e.g., 134.234.2.3. An IPv6 address may be expressed in abridged or unabridged form; however, the form chosen shall be consistent with RFC 2373.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>33</td>
<td>variable</td>
<td>String</td>
<td>REG-REQ</td>
</tr>
</tbody>
</table>
11.7.16 SKIP-ADDR-ACQUISITION

The SKIP-ADDR-ACQUISITION parameter indicates to an MS whether it should reacquire its IP address on the secondary management connection and related context or reuse its prior context.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>34</td>
<td>1</td>
<td>0: No IP address change 1: Reacquire IP address</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>

11.7.17 SAID Update Encodings field

The SAID Update Encodings field provides a translation table that allows an MS to update its security associations so that it may continue security service after an HO to a new serving BS.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (1 byte)</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAID update</td>
<td>35</td>
<td>variable</td>
<td>Compound</td>
<td>REG-RSP</td>

</tbody>
</table>

The following TLV values shall appear in each SAID Update TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (1 byte)</th>
<th>Value (variable length)</th>
</tr>
</thead>
<tbody>
<tr>
<td>New SAID</td>
<td>35.1</td>
<td>2</td>
<td>New SAID after HO to new BS</td>
</tr>
<tr>
<td>Old SAID</td>
<td>35.2</td>
<td>2</td>
<td>Old SAID before HO from old BS</td>
</tr>
</tbody>
</table>

11.7.18 Total number of provisioned service flow

When a BS shall transmit multiple DSA transactions for provisioned service flows, BS may include this TLV in REG-RSP message for provisioned service flows in order to indicate how many DSA transactions with provisioned service flows will be transmitted.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
<td>1</td>
<td>Total number of DSA transactions for provisioned service flows for an MS</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>
11.7.19 Idle mode

11.7.19.1 Idle mode timeout

This value is the MS-reported default timer value for MS idle mode timer.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>37</td>
<td>2</td>
<td>Maximum time interval between MS idle mode location updates in seconds (default = 4096 s)</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.7.20 ARQ-ACK Type

The value of this parameter specifies the ARQ ACK type supported by the MS. The MS shall transmit this parameter if ARQ is supported. The requester includes its desired setting in the REQ message. The receiver of the REQ message shall take the common part of the values it prefers and values in the REQ message. Those common values are included in the RSP message and become the agreed upon the values set. Absence of the parameter during a REG dialog shall indicate the originator of the message desires all the possible ACK type to be supported.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>1</td>
<td>Bit 0:Selective ACK entry</td>
<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1:Cumulative ACK entry</td>
<td></td>
</tr>

<td>Bit 4: Sequence block ACK entry (valid only if extended capability is supported)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 5–7: Reserved</td>
<td></td>
</tr>
</tbody>
</table>
11.7.21 MAC header and extended subheader support

The MAC Header and Subheader Support field indicates whether the MS and BS support various types of MAC header and extended subheaders. This field may be sent by either BS or MS. Omission of this field from the REG-REQ/RSP message indicates that none of the headers or subheaders are supported.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>3</td>
<td>Bit 0: BR and UL Tx power report header support</td>
<td>REG-REQ, REG-RSP</td>

<tr>
<td></td>
<td></td>
<td>Bits 17–23: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

A bit value of 0 indicates “not supported” while 1 indicates “supported.”

11.7.22 SN Reporting Base

SN Reporting Base indicates the (negative of the) base value that the MS shall use in sending fast DL measurement feedback on an enhanced fast-feedback channel.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>1</td>
<td>A positive integer in the range 0–255; the base value used in reporting shall be the negative of this value</td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>

11.7.23 MS periodic ranging timer information

This value indicates MS value of T4 timer, used for triggering the periodic ranging as described in 6.3.2.3.24 and illustrated in Figure 102.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>1</td>
<td>Unsigned integer representing MS timer T4 in seconds</td>
<td>REG-REQ</td>
</tr>
</tbody>
</table>
11.7.24 MBS capabilities

The MBS capability parameter indicates type of supported MBS service. If this TLV is included with all bits set to 0, then this shall indicate that the MS or BS does not support MBS services. A bit value of 1 indicates the associated MBS service type is supported.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>52</td>
<td>1</td>
<td>Bit 0: MBS in Serving BS Only is supported</td>

<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>1</td>
<td>Bit 0: Ability to receive requests piggybacked with data Bit 1: Ability to use 3-bit FSN values used when forming MAC PDUs on non-ARQ connections Bits 2–7: Reserved; shall be set to zero</td>
<td>SBC-REQ (see 6.3.2.3.23) SBC-RSP (see 6.3.2.3.24)</td>
</tr>
</tbody>
</table>

11.8.3 Physical Parameters Supported

11.8.3.1 Subscriber transition gaps

This field indicates the transition gap SSTTG and SSRTG for TDD and H-FDD SSs. This parameter is not used by WirelessMAN-SC. Instead, performance is mandated in Table 244.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
<td>Bits 0–7: SSTTG (μs) Bits 8–15: SSRTG (μs) Allowed values: OFDM mode: TDD and H-FDD 0…100. Other modes: TDD: 0…50; H-FDD: 0…100</td>
<td>SBC-REQ (see 6.3.2.3.23) SBC-RSP (see 6.3.2.3.24)</td>
</tr>
</tbody>
</table>

11.8.3.2 Maximum Tx power

The maximum available power for BPSK, QPSK, 16-QAM, and 64-QAM constellations. The maximum power parameters are reported in dBm and quantized in 0.5 dBm steps ranging from -64 dBm (encoded 0x00) to 63.5 dBm (encoded 0xFF). Values outside this range shall be assigned the closest extreme. SSs that do not support QAM64 shall report the value of 0x00 in the maximum QAM64 power field. This parameter is only applicable to systems supporting the OFDM or OFDMA PHY specifications.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>4</td>
<td>Bit 0–7: Maximum transmitted power for BPSK. Bit 8−15: Maximum transmitted power for QPSK. Bit 15–23: Maximum transmitted power for 16-QAM. Bit 24–31: Maximum transmitted power for 64-QAM. SSs that do not support 64-QAM shall report the value 0x00.</td>
<td>SBC-REQ</td>
</tr>
</tbody>
</table>

An OFDMA MS that supports Uplink Channel Sounding shall use the BPSK value to report the maximum transmit power for the Uplink Channel Sounding Transmission.
11.8.3.3 WirelessMAN-SC specific parameters

11.8.3.3.1 SC SS demodulator types

This field indicates the different modulation types supported by an SS for DL reception. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>

Bits 6–7: Reserved; shall be set to zero | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

11.8.3.4.4 OFDM SS TC sublayer support

This field indicates whether the SS supports the TC sublayer (see 8.3.4). A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 154  | 1      | Bit 0: TC sublayer support; default value = 0  
Bits 1–7: Reserved; shall be set to zero | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

11.8.3.4.5 OFDM private map support

The OFDM Private Map Support field indicates the private map parameters supported by a WirelessMAN-OFDM SS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 155  | 1      | Bit 0: regular private map support  
Bit 1: compressed and reduced private map support  
Bit 2–7: Reserved | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |
11.8.3.4.6 OFDM SS UL power control support

The OFDM SS UL Power Control Support field indicates the UL power control options supported by a WirelessMAN-OFDM PHY SS for UL transmission. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>

</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2–7: Reserved; shall be set to zero.</td>
<td></td>
</tr>
</tbody>
</table>

11.8.3.5 WirelessMAN-OFDMA specific parameters

11.8.3.5.1 OFDMA MS FFT sizes

The OFDMA MS FFT Sizes field indicates the FFT sizes supported by the MS. For each FFT size, a bit value of 0 indicates “not supported” while 1 indicates “supported.” This TLV also indicates which FFTs the MS can support for scanning and handover purposes. When an MS indicates it supports more than one BW, the MS shall be able to scan and handover to that BS even if the serving BS is using a different FFT.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>

</tr>
</tbody>
</table>

11.8.3.5.2 OFDMA SS demodulator

This field indicates the different demodulator options supported by a WirelessMAN-OFDMA PHY SS for DL reception. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.” The SS or BS may include bits 0–7 only and set the TLV length field to 1, in which case the receiving entity shall assume that the options represented by bits 8–15 are not supported.
This field specifies the number of DL H-ARQ channels \( n \) the SS supports, where \( n = 1..16 \). The value of the TLV shall be set to \( (n - 1) \).

<table>

### 11.8.3.5.3 OFDMA SS modulator

This field indicates the different modulator options supported by a WirelessMAN-OFDMA PHY SS for UL transmission. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>161</td>
<td>1</td>
<td>The number of DL H-ARQ channels</td>
<td>SBC-REQ (see 6.3.2.3.23)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>SBC-RSP (see 6.3.2.3.24)</td>
</tr>
</tbody>
</table>

This field specifies the number of UL H-ARQ channels \( n \) the SS supports, where \( n = 1..16 \). The value of the TLV shall be set to \( (n - 1) \).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>153</td>
<td>1</td>
<td>The number of UL_HARQ channels</td>

<tr>
<td></td>
<td></td>
<td></td>
<td>SBC-RSP (see 6.3.2.3.24)</td>
</tr>
</tbody>
</table>
11.8.3.5.4 OFDMA SS permutation support

This field indicates the different optional OFDMA permutation modes (optional PUSC, optional FUSC, and AMC) supported by a WirelessMAN-OFDMA SS. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>154</td>
<td>1</td>
<td>Bit 0: Optional PUSC support</td>
<td>SBC-REQ (see 6.3.2.3.23)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: Optional FUSC support</td>
<td>SBC-RSP (see 6.3.2.3.24)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: AMC 1x6 support</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3: AMC 2x3 support</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4: AMC 3x2 support</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 5: AMC support with HARQ map</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 6: TUSC1 support</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 7: TUSC2 support</td>
<td></td>
</tr>
</tbody>
</table>

NOTE—AMC support (bits 2–4) refers to support of AMC subchannelization using DL-MAP IE or ULMAP IE. When AMC support using HARQ map (bit 5) is indicated, all AMC types indicated in Format Configuration IE (6.3.2.3.38.2) are supported when using AMC with HARQ map.

11.8.3.5.5 OFDMA SS demodulator for MIMO support

The OFDMA SS Demodulator for MIMO Support field indicates the different MIMO options supported by a WirelessMAN-OFDMA PHY SS in the DL. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

The OFDMA SS Demodulator for MIMO Support field that follows indicates the MIMO capability of OFDMA MS demodulator. A bit value of 0 indicates “not supported” while 1 indicates “supported.”
Bits 20, 21, 22, and 23 define allocation granularity support for PUSC and AMC STC zones with dedicated pilots, respectively. They do not apply to single antenna or single stream operation. In AMC STC zone bit 22 applies only to bursts with Matrix B and bit 23 applies only to bursts with different ranks (different number of streams).

The granularity is a function of the slot duration and the pilot period. For PUSC-STC with 2 antennas, the slot duration equals 2 symbols and the pilot period equals 4 symbols. For AMC 2x3 in STC zone the slot duration equals 3 symbols and the pilot period equals 6 symbols.

If bit 20 or bit 22 are set to 1, the allocations for an MS in a DL PUSC or AMC STC zone with dedicated pilots respectively shall meet the following constraints, applicable to both non-HARQ and HARQ subbursts:

1) The allocation shall be a rectangle.
2) The smallest OFDMA symbol number of the allocation shall be a multiple the pilot period relative to the smallest OFDMA symbol number of the zone.
3) The time duration of the allocation shall be a multiple of the pilot period.

If bit 20 or bit 22 are set to 0, it indicates that the MS supports a granularity of one slot-duration (2 symbols for DL PUSC or 3 symbols for DL AMC, respectively) for an allocation in DL STC zones with dedicated pilots so long as the allocation in each subchannel in AMC and/or in each major group in PUSC is equal to or larger than the pilot period.
If bit 21 or bit 23 are set to 1, no two allocations for the MS may occupy the same slot duration in a DL PUSC or AMC STC zones with dedicated pilots respectively. For AMC, this restriction applies only to bursts with different ranks, i.e., bursts with the same rank may be concurrent. If bit 21 or bit 23 are set to 0, the MS can support multiple allocations in a given slot duration in DL PUSC or AMC STC zones with dedicated pilots respectively.

### 11.8.3.5.6 OFDMA AAS private map support

This field indicates the AAS private map parameters supported by a WirelessMAN-OFDMA SS.

- Private map chain enable indicates if a private map is allowed to point to another private map. If not enabled, private map chains are not allowed.
- The frame offset value indicates the frame offset the SS can support with private maps. A value of 0 indicates the private map allocations are for the subsequent frame (one frame in the future), a value of 1 indicates it is for two frames in the future. When used with compressed private maps, these fields are required to be used. When used with reduced private maps, these are minimum values and the actual frame offset is defined by the frame offset field in the private map.
- The concurrency field indicates how many parallel private map chains can be supported by an SS.

<table>

</tbody>
</table>

### 11.8.3.5.7 OFDMA AAS capabilities

This field indicates the different AAS options supported by a WirelessMAN-OFDMA PHY SS in the DL. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>159</td>
<td>2</td>
<td>Bit 0: AAS Zone</td>

<tr>
<td></td>
<td></td>
<td>Bit 4: UL AAS preamble</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 5–15: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

A subscriber supporting any mode of AAS should set bit 0 to indicate support of AAS zone (as specified in 8.4.5.3.3). It may, in addition, use bit 1 to indicate use of the AAS-DLFP channel specified in 8.4.4.7.
SS may indicate support of AAS preamble. An SS not supporting the preamble in DL/UL expects a preamble length of 0. Support of the AAS zone as well as support of the signaling methods “AAS Diversity Map Scan” and “AAS Direct Signaling” is relevant to both UL and DL.

### 11.8.3.5.8 OFDMA SS CINR measurement capability

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 160  | 1      | Bit 0: Physical CINR measurement from the preamble  
Bit 1: Physical CINR measurement for a permutation zone from pilot subcarriers  
Bit 2: Physical CINR measurement for a permutation zone from data subcarriers  
Bit 3: Effective CINR measurement from the preamble  
Bit 4: Effective CINR measurement for a permutation zone from pilot subcarriers  
Bit 5: Effective CINR measurement for a permutation zone from data subcarriers  
Bit 6: Support for 2 concurrent CQI channels  
Bit 7: Frequency selectivity characterization report | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

### 11.8.3.5.9 OFDMA SS UL power control support

The OFDMA SS UL Power Control Support field indicates the UL power control options supported by a WirelessMAN-OFDMA PHY SS for UL transmission. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 170  | 1      | Bit 0: UL open-loop power control support  
Bit 1: UL AAS preamble power control support.  
Bit 2–7: Reserved; shall be set to zero | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |
| 171  | 1      | Bits 0–5: The minimum number of frames that SS takes to switch from the open-loop power control scheme to the closed-loop power control scheme or vice versa  
Bits 6–7: Reserved | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

### 11.8.3.5.10 OFDMA MAP capability

The OFDMA MAP Capability field indicates the different MAP options supported by a WirelessMAN-OFDMA PHY. This field is not used for other PHY specifications. A bit value of 0 indicates “not supported” while 1 indicates “supported.”
Support for Extended HARQ IE mandates a support for SUB-DL-UL-MAP for first zone.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 172  | 1      | Bit 0: HARQ MAP Capability  
Bit 1: Extended HARQ IE capability  
Bit 2: Sub MAP capability for first zone  
Bit 3: Sub MAP capability for other zones  
Bit 4: DL region definition support  
Bits 5–7: Reserved | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

### 11.8.3.5.11 UL control channel support

The UL Control Channel Support field indicates the different UL control channels supported by a WirelessMAN-OFDMA PHY MS for UL transmission. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 173  | 1      | Bit 0: 3-bit MIMO fast feedback  
Bit 1: Enhanced fast feedback  
Under negotiation for SBC fast feedback, if enhanced feature is enabled, the SS should use only the enhanced fast-feedback channel in the CQICH allocation IE (see 8.4.5.4.13 and 8.4.5.4.14).  
Bit 2: UL ACK  
Bit 3: Reserved. Shall be set to zero.  
Bit 4: UEP fast-feedback  
Bit 5: A measurement report shall be performed on the last DL burst, as described in 8.4.11.1  
Bit 6: Primary/Secondary fast-feedback  
Bit 7: DIUC-CQI fast-feedback | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

### 11.8.3.5.12 OFDMA MS CSIT capability

The OFDMA MS CSIT Capability field indicates MS capability of supporting CSIT (UL sounding). A bit value of 0 indicates “not supported” while 1 indicates “supported.” If this field is omitted, then by default MS is considered not supporting CSIT. Capability type A indicates sounding that does not use subcarrier permutations of the DL.

Capability type B indicates sounding over subcarriers distributed according to permutations of the DL.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 174  | 2      | Bit 0: CSIT compatibility type A.  
Bit 1: CSIT compatibility type B.  
Bit 2: Power assignment capability (indicates support for nonequal power assignment)  
Bits 3–5: Sounding response time capability  
Bits 6–9: Maximum number of simultaneous sounding instructions (0 = unlimited)  
Bit 10: SS does not support P values of 9 and 18 when supporting CSIT type A  
Bits 11–15: Reserved | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |
The sounding response time capability encodings are as follows:

- Bits 3–5 Time needed for SS to respond to a sounding command transmitted by the BS
  - 000 0.5 ms
  - 001 0.75 ms
  - 010 1 ms
  - 011 1.25 ms
  - 100 1.5 ms
  - 101 min(2 ms, Next Frame)
  - 110 min(5 ms, Next Frame)
  - 111 Next Frame

11.8.3.5.13 Maximum number of bursts per frame capability in HARQ

The Maximum Number of Bursts Per Frame Capability field indicates the maximum number of UL/DL data burst allocations for the SS in a single UL/DL subframe (note that the number of UL non-HARQ burst is always limited to 1). Bursts allocated using the HARQ UL MAP IE or Persistent HARQ UL MAP IE with the ACK disable field set to 1 and bursts allocated using the HARQ DL MAP IE or Persistent HARQ DL MAP IE with the ACK disable field set to 1 shall be treated as non-HARQ bursts when counting the number of UL/DL bursts per frame per MS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 175  | 1      | Bits 0–2: One less than the maximum number of UL HARQ bursts per HARQ-enabled MS per frame. (0b000 = 1, default)  
Bit 3: Indicates whether the maximum number of UL HARQ bursts per frame (i.e., bits 0–2) includes the one non-HARQ burst. (0 = not included, default)  
Bits 4–7: One less than the maximum number of DL HARQ bursts per HARQ-enabled MS per frame. (0b0000 = 1, default) | SBC-REQ (see 6.3.2.3.23)  
SBC-RSP (see 6.3.2.3.24) |

11.8.3.5.14 OFDMA SS modulator for MIMO support

The OFDMA SS Modulator For MIMO Support field indicates the MIMO capability of OFDMA SS modulator. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>

</tbody>
</table>

11.8.3.5.17 HARQ buffer capability

DL/UL HARQ buffering capability indicates the maximal number of data bits the SS is able to store for DL/UL HARQ. The buffering capability is separately indicated for $N_{EP}/N_{SCH}$ based incremental redundancy used for CTC, and for DIUC/duration based HARQ methods (Chase combining and CC-IR), and separately for UL and DL transmissions. The buffering capability is indicated by the following two parameters:

- **Number of bits per channel.** This is the total number of data bits that the SS may buffer per HARQ channel.
- **Aggregation flag.** When this flag is clear, the number of bits is counted separately for each channel. When the flag is set, buffering capability may be shared between channels, as explained below.

The number of bits per channel is indicated as follows:

- For incremental redundancy CTC ($N_{EP}$ based): Number of bits is indicated by $N_{EP}$ code, according to Table 506.
- For Chase combining and CC-IR (DIUC based): Number of encoded bits is indicated by a value $K=0..63$ according to the following equation: $\text{Number of encoded bits} = \text{floor}(512 \times 2^{(K/4)})$ Bits.

When aggregation flag is clear, the number of bits that were allocated in each HARQ channel in the last transmission shall not exceed “Number of bits per channel.”

When aggregation flag is set, the sum over all HARQ channels, of the number of bits that were allocated in the HARQ channel in the last transmission, shall not exceed the “Number of bits per channel” multiplied by the maximum number channels supported by the SS. Note that sum total of the data bits supported is the same in both cases is the same. The number of channels supported by the SS is indicated in 11.8.3.5.3.

The IR-CTC HARQ buffer capability shall also be applied to bursts for which ACK channel is not allocated (ACK disable is set).
11.8.3.5.17.1 HARQ incremental redundancy buffer capability

11.8.3.5.19 Extended OFDMA SS CINR measurement capability

This TLV identifies extended OFDMA SS CINR measurement capabilities. A bit value of 0 indicates the attribute is not supported, while a bit value of 1 indicates the attribute is supported.

If an MS sends this TLV, it shall set bit 0 to 0b1.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| 205  | 1      | Bit 0: CINR standard deviation calculation mode

</tr>
<tr>
<td>Maximum Number of Supported Security Associations</td>
<td>Maximum number of supported SA</td>
</tr>
</tbody>
</table>

11.8.4.1 PKM version support

The PKM Version Support field indicates a PKM version. A bit value of 0 indicates “not supported” while 1 indicates “supported.” Both an SS and a BS should negotiate only one PKM version.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.1</td>
<td>1</td>
<td>Bit 0: PKM version 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: PKM version 2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 2–7: Reserved; shall be set to 0</td>
</tr>
</tbody>
</table>

11.8.4.2 Authorization policy support

The Authorization Policy Support field indicates authorization policy used by the MS and BS to negotiate and synchronize. A bit value of 0 indicates “not supported” while 1 indicates “supported.” If this field is omitted, then both SS and BS shall use the IEEE 802.16 security, constituting X.509 digital certificates and the RSA public key encryption algorithm, as authorization policy.
The PKMv2 Auth-Request/Reply/Reject/Acknowledgement messages shall be used in the RSA-based authorization procedure.

The PKMv2 EAP-Transfer message shall be used in the EAP-based authorization procedure.

Bits 4–5 are only applied to the SBC-REQ message. Those bits shall be set to 0 in the SBC-RSP message. MS and BS shall execute the reauthorization procedure according to the authorization policy negotiated in current BS when AK lifetime is expired and so on. After MS moves into another BS, MS and target BS shall execute the reauthorization procedure according to the authorization policy of HO reentry negotiated in the target BS when the lifetime of AK, which is negotiated between MS and target BS, is expired and so on.

The MS informs the BS of all supportable authorization policies by the SBC-REQ message. The BS negotiates the authorization policy. If all bits of this attribute included in the SBC-RSP message are 0, then no authorization is applied. Both the BS and the MS shall not use the authorization function.

The following table shows possible authorization policies that the MS can support.

The table shows the bit representation of Bits 0–2 and Bits 4–6 in Authorization Policy Support field in an SBC-REQ and a PKMv2 SA-TEK-Request messages.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.2</td>
<td>1</td>
<td>Bit 0: RSA-based authorization at the initial network entry&lt;br&gt;Bit 1: EAP-based authorization at the initial network entry&lt;br&gt;Bit 2: Reserved, shall be set to 0&lt;br&gt;Bit 3: Set to 0&lt;br&gt;Bit 4: RSA-based authorization at reentry&lt;br&gt;Bit 5: EAP-based authorization at reentry&lt;br&gt;Bit 6: Reserved, shall be set to 0&lt;br&gt;Bit 7: Reserved; shall be set to 0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>No Authorization (MS cannot support any authorization)</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Only EAP-based authorization</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Only RSA-based authorization</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Only RSA-based authorization or&lt;br&gt;Only EAP-based authorization or&lt;br&gt;EAP-based authorization after RSA-based authorization</td>
</tr>
</tbody>
</table>
The following table shows the bit representation of Bit 0–2 in Authorization Policy Support field in an SBC-RSP and a PKMv2 SA-TEK-Response messages.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>No Authorization</td>
<td>SBC-RSP, PKM-RSP</td>
</tr>
<tr>
<td>0 1</td>
<td>Only EAP-based authorization</td>
<td></td>
</tr>
<tr>
<td>1 0</td>
<td>Only RSA-based authorization</td>
<td></td>
</tr>
<tr>
<td>1 1</td>
<td>EAP-based authorization after RSA-based authorization</td>
<td></td>
</tr>
</tbody>
</table>

If MS and BS decide “No authorization” as their authorization policy, the MS and BS shall perform neither SA-TEK handshake nor TEK exchange procedure.

### 11.8.4.3 MAC (message authentication code) mode

The MAC Mode field indicates a message authentication code mode that MS supports. Both MS and BS shall determine and use a message authentication code mode. A bit value of 0 indicates “not supported” while 1 indicates “supported.” If this attribute is not present, only HMAC is supported.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.3</td>
<td>1</td>
<td>Bit 0: HMAC&lt;br&gt;Bit 1: Reserved&lt;br&gt;Bit 2: 64-bit short-HMAC(^a)&lt;br&gt;Bit 3: 80-bit short-HMAC(^a)&lt;br&gt;Bit 4: 96-bit short-HMAC(^a)&lt;br&gt;Bit 5: CMAC&lt;br&gt;Bit 6–7: Reserved. Set to 0</td>
</tr>
</tbody>
</table>

\(^a\)If the short-HMAC mode is selected, then the short-HMAC Tuple shall be applied to the following messages: MOB_SLP-REQ/RSP, MOB_SCN-REQ/RSP, MOB_MSHO-REQ, MOB_BSHO-REQ/RSP, MOB_HO-IND, RNG-REQ/RSP. Otherwise, the HMAC Tuple shall be applied.

The MS should support at least one message authentication code mode and inform BS of all supportable message authentication code modes by the SBC-REQ message. The BS negotiates the message authentication code mode. If all bits of this attribute included in the SBC-RSP message are 0, then no message authentication code is applied. Both the MS and the BS does not need to authenticate the MAC messages.

Short HMAC can be used only for HMAC is enabled.
11.8.4.4 PN window size

The PN Window Size field specifies the size capability of the receiver PN window for SAs and management connections. The receiver shall track PNs within this window to prevent replay attacks (see 7.5.1.2.4).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.4</td>
<td>2</td>
<td>PN Window Size in PNs</td>
</tr>
</tbody>
</table>

11.8.4.5 PKM flow control

This field specifies the maximum number of concurrent PKM transactions that may be outstanding.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.5</td>
<td>1</td>
<td>0 = No limit (default)</td>
<td>SBC-REQ, SBC-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1–255 = Maximum concurrent transactions</td>
<td></td>
</tr>
</tbody>
</table>

11.8.4.6 Maximum number of supported security associations

This field specifies the maximum number of supported security association of the SS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.6</td>
<td>1</td>
<td>Maximum number of security associations supported by the SS</td>
<td>SBC-REQ, SBC-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(default = 1)</td>
<td></td>
</tr>
</tbody>
</table>

11.8.5 Extended subheader capability

The Extension Capability field specifies extended subheader capability supports.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>27</td>
<td>1</td>
<td>Bit 0: Support extended subheader format</td>
<td>SBC-REQ, SBC-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: PDU SN(short) extended subheader</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: PDU SN(long) extended subheader</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 3–7: Reserved</td>
<td></td>
</tr>
</tbody>
</table>
11.8.6 HO trigger metric support

The HO Trigger Metric Support field indicates trigger metrics that MS or BS supports. For each bit, a value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>1</td>
<td>Bit 0: BS CINR mean</td>
<td>SBC-REQ, SBC-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: BS RSSI mean</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: Relative delay</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3: BS RTD</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4–7: Reserved, shall be set to zero</td>
<td></td>
</tr>
</tbody>
</table>

11.8.7 Association type support

The Association Type Support field indicates the association level supported by the MS or the BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>167</td>
<td>1</td>
<td>Bit 0: Scanning without Association: Association not supported</td>
<td>SBC-REQ (see 6.3.2.3.23) SBC-RSP (see 6.3.2.3.24)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: Association level 0: Scanning or association without coordination.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: Association level 1: association with coordination.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3: Association level 2: network assisted association.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4: Directed association support.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 5–7: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

If a bit is set to 1, then MS or BS indicates support at the respective association type and level. The MS may associate according to arrangements by the BS at levels up to and including the one for which the MS has indicated support.

11.8.9 Service Information Query (SIQ)

Service Information Query is included by MS in SBC-REQ to request the Service Network Provider Identifier(s) supported by the Operator Network that includes the current BS.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIQ</td>
<td>29</td>
<td>1</td>
<td>Bit 0: indicates that the SS requests transmittal of the NSP List TLV for the list of NSP IDs supported by the Operator Network that includes the current BS;</td>
<td>SBC-REQ</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Bit 1: indicates that the SS requests transmittal of the Verbose NSP Name List TLV, in addition to the NSP List TLV; bit 1 shall not be set to a value of ‘1’ unless bit 0 is also set to a value of ‘1’;</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Bit 2–7: Reserved</td>
<td></td>
</tr>
</tbody>
</table>
11.8.10 MIH Capability Supported

The “MIH Capability Supported” TLV indicates if MIH Function is supported. MSs and BSs that support the MIHF shall identify themselves by including this TLV and setting at least bit 0 of its value field to 1. MSs and BSs that do not support the IEEE 802.21 MIHF shall not support the MOB_MIH-MSG management message. A BS may provide a network discovery query mechanism during network entry using MIH frames. A BS shall indicate support for this capability using bits 4 and 5.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>46</td>
<td>1</td>
<td>Indicates the capability of IEEE 802.21 Media Independent Handover Services. Each bit set to 1 indicates that the corresponding service is supported. If bit 0 is set to 1 in the SBC-REQ/RSP message, the BS/MS is permitted to send MOB_MIH-MSG messages (see 6.3.2.3.57) as further indicated through bits 1–3. If bit 0 is set to 0, bits 1–3 shall be set to 0. If bit 4 is set to be 1 in the SBC-RSP message, the MS is allowed to transmit an MIH information service request in an MIH Initial Service Request message (see 6.3.2.3.9). When bit 5 is set to be 1 in the SBC-RSP message, the MS is allowed to transmit an MIH request for ES/CS Capability discovery in an MIH Initial Service Request message (see 6.3.2.3.9).</td>
<td></td>
</tr>
</tbody>
</table>

Bit 0 = MIH (Media Independent Handover) support  
Bit 1 = Event Service support  
Bit 2 = Command Service support  
Bit 3 = Information Service support  
Bit 4 = Information Service support during network entry  
Bit 5 = ES/CS capability discovery support during network entry  
Bits 6–7: Reserved

11.8.11 Visited NSP ID

When an MS attempts to connect to an operator network that is not the MS home network, and the roam operator network has a relationship with the MS home network, and multiple Network Service Providers with differing AAA Services are available for authentication through the roam operator network, the MS may include the Visited NSP ID in the SBC-REQ message to indicate to the roam operator network which NSP the MS intends to be the conduit for authentication to the MS home network. If the BS requires the information provided by the Visited NSP ID in order to complete the initial network entry and the Visited NSP ID is not included in the SBC-REQ message, the BS may terminate the current attempt at initial network entry.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visited NSP ID</td>
<td>180</td>
<td>3</td>
<td>NSP ID of the Network Service Provider the MS intends to be the conduit for authentication to the MS home network.</td>
<td>SBC-REQ</td>
</tr>
</tbody>
</table>
11.8.12 Auth Type for Single EAP

Auth Type for Single EAP identifies the authorization type used in initial network entry when the authorization method is single EAP. Auth Type for Single EAP identifies the authorization type as either device authorization or user authorization.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auth Type for Single EAP</td>
<td>181</td>
<td>1</td>
<td>Auth Type for Single EAP shall only be included when bit 1 of MS Auth Policy support (see 11.8.4.2) has a value of ‘1’. Only one of the bit indicators, bit 0 or bit 1 of Auth Type for Single EAP, shall be set to a value of ‘1’. Bit 0: device authentication Bit 1: user authentication Bit 2–7: Reserved</td>
</tr>
</tbody>
</table>

11.8.13 Visited NSP Realm

When an MS attempts to connect to an operator network that is not the MS home network, and the roamed operator network has a relationship with the MS home network, and the MS authorization method is EAP, the BS may include the Visited NSP Realm in the SBC-RSP message to the MS to provide the realm of the AAA Services through which the MS intends to use to route the AAA messages for authentication to the MS home network. The MS may use the Visited NSP Realm to decorate an EAP NAI for the MS EAP transactions to its home network.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visited NSP Realm</td>
<td>182</td>
<td>variable</td>
<td>Visited NSP Realm is a variable length string.</td>
</tr>
</tbody>
</table>

11.8.14 SII-ADV Message Pointer

When a BS elects to send information requested in an SBC-REQ message in an SII-ADV message rather than in the SBC-RSP message, this TLV is used to provide a pointer to the frame in which an SII-ADV message is transmitted.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SII-ADV Message Pointer</td>

</tr>
</tbody>
</table>
11.8.15 SDU MTU capability

The maximum MTU capability TLV specifies the upper bound for the SDU MTU size supportable on transport connections.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum MTU capability</td>
<td>184</td>
<td>2</td>
<td>An unsigned 16 bit integer. When in SBC-REQ: The maximum SDU, in bytes, that the BS may send to the SS on transport connections. When in SBC-RSP: The maximum SDU, in bytes, that the SS may send to the BS or receive from the BS on transport connections.</td>
<td>SBC-REQ SBC-RSP</td>
</tr>
</tbody>
</table>

11.8.16 DL Coordinated Zone capability

The “DL coordinated zone capability” field indicates that MS can exploit the knowledge of interference if the zone is coordinated between BSs (i.e., the MS in the serving sector will experience interference from coordinated BS transmission that start from the same symbol, with the same zone type, and with the same pilot positions). This field is optional. A bit value of 0 indicates “not supported” while 1 indicates “supported.”

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
</table>
| DL Coordinated Zone Capability | 186  | 1      | Bit 0: Support DL coordinated zone for non-STC PUSC  
Bit 1: Support DL coordinated zone for STC PUSC  
Bit 2: Support DL coordinated zone for AMC  
Bit 3: Support DL coordinated zone for STC AMC  
Bits 4–7: Reserved | SBC-REQ |

11.9 PKM-REQ/RSP management message encodings

A summary of the TLV encoding format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 byte</td>
<td>variable</td>
<td>Length bytes</td>
<td></td>
</tr>
</tbody>
</table>

The Type field is 1 byte. Values of the PKM Type field are specified in Table 592. Note that type values between 0 and 127 are defined within the PKM Specification, while values between 128 and 255 are vendor-assigned attribute types.

- A PKM server shall ignore attributes with an unknown type.
- A PKM client shall ignore attributes with an unknown type.
PKM client and server (i.e., SS and BS) may log receipt of unknown attribute types.

The Length field indicates the length of this attribute’s Value field, in bytes. The length field does not include the Type and Length fields.

The Value field is zero or more bytes and contains information specific to the attribute. The format and length of the Value field is determined by the Type and Length fields. The format of the Value field is one of the five data types shown in Table 593.

<tr>
<td>uint32</td>
<td>32-bit unsigned integer</td>
</tr>
<tr>
<td>compound</td>
<td>Collection of attributes</td>
</tr>
</tbody>
</table>

### 11.9.1 Display string

The Display-String attribute contains a textual message. It is typically used to explain a failure response and might be logged by the receiver for later retrieval by an SNMP manager. Display strings shall be no longer
than 128 bytes. A summary of the Display-String attribute format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>&gt; 0 and ≤ 128</td>
<td>A string of characters. The character string shall be null-terminated.</td>
</tr>
</tbody>
</table>

### 11.9.2 AUTH-Key

The AK (AUTH-Key) is a 20 byte quantity, from which a KEK, and two message authentication keys (one for UL requests, and a second for DL replies) are derived. This attribute contains a 128 byte quantity containing the AK RSA-encrypted with the SS’s 1024 bit RSA public key. Details of the RSA encryption procedure are given in 7.5. The ciphertext produced by the RSA algorithm shall be the length of the RSA modulus, i.e., 128 bytes.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>128</td>
<td>128-byte quantity representing an RSA-encrypted AK.</td>
</tr>
</tbody>
</table>

### 11.9.3 TEK

The TEK attribute contains a quantity that is a TEK key, encrypted with a KEK derived from the AK.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>8</td>
<td>Encrypted TEK for DES</td>
</tr>
<tr>
<td></td>
<td>16</td>
<td>Encrypted TEK for AES</td>
</tr>
<tr>
<td></td>
<td>24</td>
<td>Encrypted TEK for AES key wrap</td>
</tr>
<tr>
<td></td>
<td>128</td>
<td>Encrypted TEK for RSA</td>
</tr>
</tbody>
</table>

When the TEK encryption algorithm identifier in the SA is 0x01, the length shall be 8, and the TEK shall be encrypted with 3DES in EDE mode according to the procedure defined in 7.5.2.1.

When the TEK encryption algorithm identifier in the SA is 0x03, the length shall be 16, and the TEK shall be encrypted with AES in ECB mode according to the procedure in 7.5.2.3.

When the TEK encryption algorithm identifier in the SA is 0x04, the length shall be 24, and the TEK shall be encrypted with the AES key wrap algorithm according to the procedure in 7.5.2.4.
Table 594 shows all the TEK encryption algorithm identifiers.

### Table 594—TEK encryption algorithm identifiers

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>ECB mode AES with 128-bit key</td>
</tr>
<tr>
<td>4</td>
<td>AES key wrap with 128-bit key</td>
</tr>
<tr>
<td>5–255</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

#### 11.9.4 Key lifetime

The Key-Lifetime attribute contains the lifetime, in seconds, of an AK, a TEK, a PAK, or a PMK. It is a 32-bit unsigned quantity representing the number of remaining seconds for which the associated key shall be valid. Note that this attribute can be used as a single TLV or as part of a compound TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint32)</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>4</td>
<td>32-bit quantity representing key lifetime. A key lifetime of zero indicates that the corresponding key is not valid.</td>
</tr>
</tbody>
</table>

#### 11.9.5 Key sequence number

The Key-Sequence-Number attribute contains sequence number for a TEK, an AK, a PAK, or a PMK. The 2-bit or 4-bit quantity, however, is stored in a single byte, with the high-order 6 or 4 bits set to 0. A summary of the Key-Sequence-Number attribute format is shown below. Note that this attribute can be used as a single TLV or as part of a compound TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1</td>
<td>2-bit sequence number (TEK, GTEK) 4-bit sequence number (AK, PAK, PMK, GKEK)</td>
</tr>
</tbody>
</table>
11.9.6 HMAC digest

The HMAC-Digest attribute contains a keyed hash used for message authentication. The HMAC algorithm is defined in IETF RFC 2104.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>20 bytes</td>
<td>A 160-bit (20 byte) keyed SHA hash</td>
</tr>
</tbody>
</table>

11.9.6.1 Short-HMAC digest

The Short-HMAC-Digest attribute contains the highest order bytes of the keyed hash used for message authentication. The HMAC algorithm is defined in IETF RFC 2104. The 20-byte HMAC result is truncated to the length indicated by the BS in the Short-HMAC Digest Length parameter (see 11.1.2.3) or to 10 bytes if the Short-HMAC Digest Length parameter was not specified.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>variable</td>
<td>The highest order bytes of the truncated HMAC-SHA1 keyed hash</td>
</tr>
<tr>
<td></td>
<td>(8, 10, or 12 bytes as described in 11.1.2.3)</td>
<td></td>
</tr>
</tbody>
</table>

11.9.7 SAID

The SAID attribute contains a 16-bit SAID used by the Privacy Protocol to identify the SA. The SAID for the multicast service or the broadcast service is the GSAID. Null SAID shall be used when “No authorization” is applied. The value of Null SAID is 0xffff. When allocating SAID during handover re-entry, target BS should assign the same SAIDs which were used in serving BS and each newly assigned SAID shall match the cryptographic suite that was used in serving BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>2</td>
<td>16-bit quantity representing an SAID</td>
</tr>
</tbody>
</table>

11.9.8 TEK parameters

The TEK-Parameters attribute is a compound attribute, consisting of a collection of subattributes. These subattributes represent all security parameters relevant to a particular generation of an SAID’s TEK. A summary of the TEK-Parameters attribute format is shown below. The GTEK and GKEK are defined only for the multicast service or the broadcast service. The GTEK is the TEK for the multicast service or the broadcast service.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>variable</td>
<td>The Compound field contains the subattributes as defined in Table 595</td>
</tr>
</tbody>
</table>
The CBC-IV attribute is required when the data encryption algorithm identifier in the SA ciphersuite is 0x01 (DES in CBC mode).

The CBC-IV attribute is not required when the data encryption algorithm identifier in the SA ciphersuite is 0x02 (AES).

The CBC-IV attribute is required when the data encryption algorithm identifier in the SA ciphersuite is 0x03 (AES in CBC mode).

### 11.9.9 CBC-IV attribute

The CBC-IV attribute contains a value specifying a CBC IV. A summary of the CBC-IV attribute format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>Equal to Block length of cipher</td>
<td>CBC-IV</td>
</tr>
</tbody>
</table>

### 11.9.10 Error code

The Error-Code attribute contains a 1-byte error code providing further information about an Authorization Reject, Key Reject, Authorization Invalid, or TEK Invalid. A summary of the Error-Code attribute format is shown below. Table 596 lists code values for use with this attribute. The BS may employ the nonzero error codes (1–6) listed below; it may, however, return a code value of zero (0). Error code values other than those defined in Table 596 shall be ignored. Returning a code value of zero sends no additional failure information to the SS; for security reasons, this may be desirable.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint8)</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>1</td>
<td>Error-Code</td>
<td>Authorization Reject, Authorization Invalid, Key Reject, TEK Invalid</td>
</tr>
</tbody>
</table>
Error Code 6 (Permanent Authorization Failure) is used to indicate a number of different error conditions affecting the PKM authorization exchange. These include the following:

a) An unknown manufacturer; i.e., the BS does not have the CA certificate belonging to the issuer of an SS certificate
b) SS certificate has an invalid signature
c) ASN.1 parsing failure during verification of SS certificate
d) SS certificate is on the “hot list”
e) Inconsistencies between certificate data and data in accompanying PKM attributes
f) SS and BS have incompatible security capabilities

The common property of these error conditions is that the failure condition is considered permanent; any reattempts at authorization would continue to result in Authorization Rejects. Details about the cause of a Permanent Authorization Failure may be reported to the SS in an optional Display-String attribute that may accompany the Error-Code attribute in Authorization Reject messages. Note that providing this additional detail to the SS should be administratively controlled within the BS. The BS may log these Authorization failures, or even trap them to an SNMP manager.

### 11.9.11 CA certificate

The CA-Certificate attribute is a string attribute containing an X.509 CA Certificate, as defined in 7.6. A summary of the CA-Certificate attribute format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>17</td>
<td>variable. Length shall not cause resulting MAC management message to exceed the maximum allowed size.</td>
<td>X.509 CA Certificate (DER-encoded ASN.1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Error code</th>

</tr>
<tr>
<td>5</td>
<td>Auth Invalid</td>
<td>Message (Key Request) authentication failure</td>
</tr>
<tr>
<td>6</td>
<td>Auth Reject</td>
<td>Permanent Authorization Failure</td>
</tr>
</tbody>
</table>
11.9.12 SS certificate

The SS-Certificate attribute is a string attribute containing an SS’s X.509 User Certificate, as defined in 7.6. A summary of the SS-Certificate attribute format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (string)</th>
</tr>
</thead>
<tbody>
<tr>
<td>18</td>
<td>variable</td>
<td>X.509 SS Certificate (DER-encoded ASN.1)</td>
</tr>
</tbody>
</table>

Length shall not cause resulting MAC management message to exceed the maximum allowed size.

11.9.13 Security capabilities

The Security-Capabilities attribute contains the cryptographic suite(s) an SS supports.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>

11.9.15 Cryptographic-Suite-List parameter

The Cryptographic-Suite-List parameter contains a list of supported cryptographic suites.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>21</td>
<td>$5 \times n$, where $n$ equals number of cryptographic suites listed</td>
<td>A list of cryptographic suites</td>
</tr>
</tbody>
</table>

11.9.16 SA-Descriptor attribute

The SA-Descriptor attribute is a compound attribute whose subattributes describe the properties of a security association (SA). These properties include the SAID, the SA type, the SA service type, and the cryptographic suite employed within the SA.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>$variable$</td>
<td>The Compound field contains the subattributes shown in Table 602</td>
</tr>
</tbody>
</table>
11.9.17 SA-Type attribute

The SA-Type attribute identifies the type of SA. Privacy defines three SA types: Primary, Static, Dynamic.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (uint8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>24</td>
<td>1</td>
<td>A 1-byte code identifying the value of SA type as defined in Table 603</td>
</tr>
</tbody>
</table>

11.9.18 PKM Configuration Settings field

The PKM Configuration Settings field defines the parameters associated with PKM operation. It is composed of a number of encapsulated TLV fields.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (compound)</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>27</td>
<td>variable</td>
<td>Compound</td>
<td>Auth Reply, PMKv2-RSA reply, PKMv2-SA-TEK response</td>
</tr>
</tbody>
</table>
11.9.18.1 Authorize Wait Timeout field

The value of the Authorize Wait Timeout field specifies retransmission interval, in seconds, of Authorization Request messages from the Authorize Wait state.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.1</td>
<td>4</td>
<td>Authorize Wait Timeout in seconds</td>
</tr>
</tbody>
</table>

11.9.18.2 Reauthorize Wait Timeout field

The value of the Reauthorize Wait Timeout field specifies retransmission interval, in seconds, of Authorization Request messages from Reauthorize Wait state.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.2</td>
<td>4</td>
<td>Reauthorize Wait Timeout in seconds</td>
</tr>
</tbody>
</table>

11.9.18.3 Authorization Grace Time field

The value of the Authorization Grace Time field specifies the grace period for reauthorization, in seconds.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.3</td>
<td>4</td>
<td>Authorization Grace Time in seconds</td>
</tr>
</tbody>
</table>

11.9.18.4 Operational Wait Timeout field

The value of the Operational Wait Timeout field specifies the retransmission interval, in seconds, of Key Requests from the Operational Wait state.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.4</td>
<td>4</td>
<td>Operational Wait Timeout in seconds</td>
</tr>
</tbody>
</table>

11.9.18.5 Rekey Wait Timeout field

The value of the Rekey Wait Timeout field specifies the retransmission interval, in seconds, of Key Requests from the Rekey Wait state.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.5</td>
<td>4</td>
<td>Rekey Wait Timeout in seconds</td>
</tr>
</tbody>
</table>
11.9.18.6 TEK Grace Time field

The value of the TEK Grace Time field specifies grace period, in seconds, for rekeying the TEK.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.6</td>
<td>4</td>
<td>TEK Grace time in seconds</td>
</tr>
</tbody>
</table>

11.9.18.7 Authorize Reject Wait Timeout field

The value of the Authorize Reject Wait Timeout field specifies how long (in seconds) an SS waits in the Authorize Reject Wait state after receiving an Authorization Reject.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.7</td>
<td>4</td>
<td>Authorize Reject Wait Timeout in seconds</td>
</tr>
</tbody>
</table>

11.9.19 Nonce attribute

The Nonce attribute contains a quantity used to protect message exchanges from Replay Attack. As always, values for nonces should be generated using reliable random or pseudo-random generators.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>29</td>
<td>4</td>
<td>Randomly generated value</td>
</tr>
</tbody>
</table>

11.9.20 SS_RANDOM attribute

The SS_RANDOM attribute contains a quantity that is pseudo random number generated from the MS and used as fresh number for mutual authorization message handshake.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>33</td>
<td>8</td>
<td>MS-generated random number</td>
</tr>
</tbody>
</table>

11.9.21 BS_RANDOM attribute

The BS_RANDOM attribute contains a quantity that is pseudo random number generated from the BS and used as fresh number for mutual authorization message handshake.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>34</td>
<td>8</td>
<td>BS-generated random number</td>
</tr>
</tbody>
</table>
11.9.22 Encrypted Pre-PAK attribute

This pre-primary authorization key (PAK) is a 256 bit quantity, from which an AK, a KEK, two MAC message authentication keys, and two EAP message protection keys are derived. This attribute contains a 128 byte quantity containing the PAK RSA-encrypted with the MS’s 1024-bit RSA public key. Details of the RSA encryption procedure are given in 7.2.2.2. The ciphertext produced by the RSA algorithm shall be the length of the RSA modulus, i.e., 128 bytes.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>35</td>
<td>128</td>
<td>128-byte quantity representing an RSA-encrypted pre-PAK, which generates PAK</td>
</tr>
</tbody>
</table>

11.9.23 BS-Certificate attribute

The BS-Certificate attribute is a string attribute containing an X.509 BS Certificate, as defined in 7.1.3.1. A summary of the BS-Certificate attribute format is shown below. The fields are transmitted from left to right.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>37</td>
<td>variable</td>
<td>X.509 BS Certificate (DER-encoded ASN.1)</td>
</tr>
</tbody>
</table>

Length shall not cause resulting MAC management message to exceed the maximum allowed size.

11.9.24 SigBS attribute

The SigBS attribute contains a RSA signature computed over the PKMv2 RSA Reply message or the PKMv2 RSA Reject message with the BS’s private key.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>38</td>
<td>128</td>
<td>An RSA signature computed over all attributes included in the PKMv2 RSA Reply message or the PKMv2 RSA Reject message with the BS’s private key. This value is calculated using PKCS #1 OAEP 1.5 signing algorithm with SHA-1 hash.</td>
</tr>
</tbody>
</table>

11.9.25 MS-MAC Address attribute

The MS-MAC Address attribute is the MAC address of MS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>39</td>
<td>6</td>
<td>The MAC address of the MS</td>
</tr>
</tbody>
</table>
11.9.26 CMAC Digest attribute

The CMAC Digest attribute contains a PN counter, CMAC_PN_*, incremented per packet on each direction and the Message Authentication Code value used for message authentication. The CMAC algorithm is defined in NIST Special Publication 800-38B.

The CMAC Digest includes the following:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>12</td>
<td>See that follows</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Length (bits)</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMAC Packet Number Counter, CMAC_PN_*</td>
<td>32</td>
<td>This context is different in UL and DL.</td>
</tr>
<tr>
<td>CMAC Value</td>
<td>64</td>
<td>CMAC with AES-128.</td>
</tr>
</tbody>
</table>

11.9.27 Key push modes

The Key Push Modes field is used to distinguish usage code of a PKMv2 Group-Key-Update-Command message.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>1</td>
<td>0: GKEK update mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: GTEK update mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2–255: Reserved</td>
</tr>
</tbody>
</table>

A PKMv2 Group-Key-Update-Command message for the GKEK update mode is to distribute new GKEK to each SS carried on the primary management connection. The BS transmits this message before the M&B TEK Grace Time starts.

A PKMv2 Group-Key-Update-Command message for the GTEK update mode is to distribute new GTEK to all SS carried on the broadcast connection. The BS transmits this message after the M&B TEK Grace Time starts.

Attributes of a PKMv2 Group-Key-Update-Command message are different according to the value of the Key Push Modes as shown in the following table.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GKEK update mode</th>
<th>GTEK update mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key-Sequence-Number</td>
<td>AK Sequence Number</td>
<td>GKEK Sequence Number</td>
</tr>
<tr>
<td>GSAID</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Key Push Modes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Key-Sequence-Number, GSAID, Key Push Modes, and HMAC/CMAC-Digest fields are included in two PKMv2 Group-Key-Update-Command message regardless of the value of the Key Push Modes.

GKEK-Parameters attribute should be included in a PKMv2 Group-Key-Update-Command message for the GKEK update mode. And GTEK-Parameters attribute should be included in that message for the GTEK update mode.

The CBC-IV attribute can be included only when the TEK encryption algorithm identifier in the cryptographic suite equal to 0x01.

One of HMAC Digest or CMAC Digest shall be used to authenticate the Key Update Command messages.

**11.9.28 Key push counter**

The Key Push Counter field is used to protect for replay attack. This value is one greater than (modulo 65536) that of older generation.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>42</td>
<td>2</td>
<td>16-bit counter</td>
</tr>
</tbody>
</table>

**11.9.29 GKEK**

The 128-bit GKEK may be randomly generated in a BS or an ASA server. The GKEK field is used to encrypt the GTEK for the multicast service or the broadcast service.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>16</td>
<td>GKEK, encrypted with the KEK derived from AK</td>
</tr>
</tbody>
</table>
11.9.30 SigSS

The SigSS attribute contains an RSA signature computed over the PKMv2 RSA Request message or the PKMv2 RSA Acknowledgement message with the SS’s private key.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>128</td>
<td>An RSA signature computed over all attributes included in the PKMv2 RSA Request message or the PKMv2 RSA Acknowledgement message with the SS’s private key. This value is calculated using RSASSA-PKCS-v1_5-Sign algorithm with SHA-1 hash.</td>
</tr>
</tbody>
</table>

11.9.31 Authorization key identifier (AKID)

The AKID attribute identifies the AK as defined in Table 202.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>45</td>
<td>8</td>
<td>AKID as defined in Table 202</td>
</tr>
</tbody>
</table>

11.9.32 EAP payload

The EAP-Payload attribute contains the payload used in the upper EAP authorization layer. The security sublayer does not interpret this attribute.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>variable</td>
<td>EAP payload</td>
</tr>
</tbody>
</table>

11.9.33 Auth result code

The Auth-Result-Code attribute contains the result code of the RSA-based authorization (only for PKMv2).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>30</td>
<td>1</td>
<td>0: Success 1: Reject 2–255: Reserved.</td>
</tr>
</tbody>
</table>
11.9.34 SA service type

The SA-Service-Type attribute indicates service types of the corresponding SA type. This attribute shall be defined only when the SA type is Static SA or Dynamic SA. The GTEK shall be used to encrypt connection for group multicast service. The MTK shall be used to encrypt connection for MBS service.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>1</td>
<td>0: Unicast service</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Group multicast service</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2: MBS service</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3–255: Reserved</td>
</tr>
</tbody>
</table>

11.9.35 Frame number

The Frame-Number attribute contains a 24-bit absolute frame number in which the old PMK and all its associate AKs should be discarded. The value is in MSB first order.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>3</td>
<td>24-bit Frame Number in MSB first order</td>
</tr>
</tbody>
</table>

11.9.36 Associated GKEK Sequence Number

This attribute indicates the GKEK Sequence Number of a GKEK-Parameters attribute under the same GSAID. When a BS transfers the GTEK, BS shall encrypt the GTEK using the GKEK corresponding to the Associated GKEK Sequence Number.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (Compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>46</td>
<td>1</td>
<td>Associated GKEK sequence number</td>
</tr>
</tbody>
</table>

11.9.37 GKEK-Parameters

This attribute is a compound attribute, consisting of a collection of subattributes. These subattributes represent all the security parameters relevant to a particular generation of a GSAID for encrypting the GTEK in the multicast or broadcast service. A summary of the GKEK-Parameters attribute format is shown below.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value (Compound)</th>
</tr>
</thead>
<tbody>
<tr>
<td>47</td>
<td>variable</td>
<td>The Compound field contains the subattributes as defined in the following table.</td>
</tr>
</tbody>
</table>
The GKEK lifetime should be made by $n$ times the GTEK lifetime as follows.

$$\text{GKEK lifetime} = n \times \text{GTEK lifetime}$$

where $n$ is an integer (more than 1).

### 11.9.38 MIH Cycle

This TLV includes the 8 LSB of the absolute frame number of the first frame where the MIH response is expected to be ready for transmittal to the MS, and the interval between subsequent frames where the MIH response may be transmitted (refer to 6.3.24).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>48</td>
<td>2</td>
<td>Bit 8–15: Specify the 8 LSB of the absolute frame number when the BS may indicate that the MIH response is ready to be delivered to the MS by allocating bandwidth for the MS in the UL-MAP, if it is uncasting the MIH response, or when the BS may send an SII-ADV message including the MIH response (refer to 6.3.24), if the BS is broadcasting the MIH response. Bit 0–7: Specify the MIH Cycle Offset. The MIH Cycle Offset is used to indicate subsequent frames when the BS may allocate bandwidth for the MS in the UL-MAP or send an SII-ADV message including the MIH response. The subsequent frames are calculated by adding multiples of the MIH Cycle Offset to the original absolute frame number transmission opportunity.</td>
<td>PKM-RSP</td>
</tr>
</tbody>
</table>

### 11.9.39 MIH Delivery Method and Status Code

This TLV is used by the MS and BS to negotiate a preferred delivery method (broadcast or unicast). Only the BS may transmit a Status Code value different from 0x00 (Null).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>49</td>
<td>1</td>
<td>Bit 0: Unicast Bit 1: Broadcast Bit 2–6: Status code 0x00: Null 0x01: Requested information is not available. 0x02–0x1F: Reserved Bit 7: Reserved</td>
<td>PKM-REQ PKM-RSP</td>
</tr>
</tbody>
</table>
11.10 MCA-REQ management message encodings

The type values used shall be those defined in Table 605.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type (1 byte)</th>
<th>Length</th>
<th>Value (variable-length)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multicast CID</td>
<td>1</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>Assignment</td>
<td>2</td>
<td>1</td>
<td>0x00 = Leave multicast group</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>0x01 = Join multicast group</td>
</tr>
<tr>
<td>Multicast group type</td>
<td>3</td>

<td>0 = Regular (not AAS), default</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 = AAS</td>
</tr>
<tr>
<td>Periodic allocation parameters</td>
<td>4</td>
<td>4</td>
<td>Bit 0–7 = m</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Bit 8–15 = k</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Bit 16–23 = n</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Bit 24–31 = Reserved; shall be set to zero</td>
</tr>
<tr>
<td>Periodic allocation type</td>
<td>5</td>
<td>1</td>
<td>0 = REQ region Full</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 = REQ region Focused</td>
</tr>
<tr>
<td>Operation</td>
<td>6</td>
<td>1</td>
<td>0 = Allocate</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 = Deallocate</td>
</tr>
<tr>
<td>Reserved</td>
<td>7–255</td>
<td></td>
<td>Reserved for future use</td>
</tr>
</tbody>
</table>

Parameters $m$, $k$ have the following meaning: multicast group gets a multicast polling allocation at the end of the frame $#N$ if $N \mod k = m$; size of the allocation is $n$.

11.11 REP-REQ management message encodings

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>

</tbody>
</table>
| Zone-specific effective CINR request| 1.6  | 2      | Bits 0–2: Type of zone on which effective CINR is to be reported:  
0b000: PUSC zone with Use All SC = 0.  
0b001: PUSC zone with Use All SC = 1 / PUSC AAS zone.  
0b010: FUSC zone.  
0b011: Optional FUSC zone.  
0b100: Reserved.  
0b101: AMC zone (for DL AAS zone or AMC Zone with dedicated pilots)  
0b110–0b111: Reserved.  
Bit 3:  
1: Zone for which effective CINR should be reported is STC zone.  
0: Otherwise.  
Bit 4:  
1: Zone for which effective CINR should be estimated is AAS zone or zone with dedicated pilots.  
0: Otherwise.  
Bits 5–6: PRBS_ID of the zone for which effective CINR should be reported. Ignored for Safety Channel.  
Bit 7: Data/pilot-based effective CINR measurement:  
0: Report the CINR estimate from pilot subcarriers.  
1: Report the CINR estimate from data subcarriers.  
Bits 8–13: Reported effective CINR shall only be estimated for the subchannels of PUSC major groups for which the corresponding bit is set. Bit (k+7) refers to major group k. Only applicable for CINR measurement on a PUSC zone.  
Bits 14–15: Reserved; shall be set to zero.  

| Preamble effective CINR request     | 1.7  | 1      | Bits 0–1: Type of preamble-based effective CINR measurement:  
0b00: Report the estimation of effective CINR measured from preamble for frequency reuse configuration = 1.  
0b01: Report the estimation of effective CINR measured from preamble for frequency reuse configuration = 3.  
0b10–0b11: Reserved.  
Bits 2–7: Reserved; shall be set to zero.  

| Channel selectivity report          | 1.8  | 1      | Bit 0: 1 = Include frequency selectivity report.  
Bits 1–7: Reserved; shall be set to zero.  

| Midamble Physical CINR request      | 1.9  | 1      | Midamble Physical CINR request is used with Channel Type Request = 0b01 (band AMC) to report CINR on the midamble.  
Bits 0–3: $\alpha_{avg}$ in multiples of 1/16 (range is [1/16, 16/16]).  
Bit 4:  
0: Report only mean of CINR.  
1: Report both mean and standard deviation of CINR.  
Bit 5–6  
0b00: report CINR assuming 1 stream  
0b01: report CINR assuming 2 streams  
0b10: report CINR using number of streams determined by MS  
0b11: reserved  
Bits 7: reserved; shall be set to zero.  

Copyright © 2009 IEEE. All rights reserved.
Measurements according to Zone-specific physical CINR request TLV (1.4) and Preamble physical CINR request TLV (1.5) and Midable physical CINR request TLV (1.9) shall use the $\alpha_{\text{avg}}$ specified in these TLVs regardless of the value of the $\alpha_{\text{avg}}$ in Report Type TLV (1.1).

### 11.12 REP-RSP management message encodings

NOTE—CQICH_ID applies to triggered update (see 6.3.17.2) for CQI channel allocated with a CQICH_ID and shall be zero in all other cases.
NOTE—CQICH_ID applies to triggered update (see 6.3.17.2) for CQI channel allocated with a CQICH_ID and shall be zero in all other cases.

For the type 2.1 through 2.5, the 5-bit CINR measurement encoding shown in Equation (171) shall be used.

\[
\begin{align*}
    n &= \begin{cases} 
    0 & CINR \leq -3dB \\
    n & (n - 4)dB < CINR \leq (n - 3)dB, 0 < n < 31 \\
    31 & CINR > 27dB
    \end{cases} 
\end{align*}
\]  

(171)

For the TLVs with types 2.6 through 2.15, the 5-bit physical CINR measurement encoding shown in Equation (172) shall be used.

\[
\begin{align*}
    \text{Payload bits} &= \begin{cases} 
    0 & CINR \leq -3dB \\
    n & (n - 4) < CINR \leq (n - 3), 0 < n < 31 \\
    31 & CINR > 27dB
    \end{cases} 
\end{align*}
\]  

(172)

### 11.13 Service flow management encodings

Table 606 and 11.13.1 through 11.13.35 define the parameters associated with UL/DL scheduling for a service flow. It is somewhat complex in that it is composed from a number of encapsulated TLV fields.

Note that the encapsulated UL and DL flow classification configuration setting strings share the same subtype field numbering plan because many of the subtype fields defined are valid for both types of configuration settings except service flow encodings.
UL encodings use the type 145. DL encodings use the type 146. Entries of the form [145/146] indicate the encoding can be applied to either an UL or DL service flow.

### 11.13.1 SFID

The SFID is used by the BS as the primary reference of a service flow within the SS. Only the BS may issue a SFID for an SS. It uses this parameterization to issue SFIDs in BS-initiated DSA-REQ/DSC-REQ messages and in its DSA-RSP/DSC-RSP to SS-initiated DSA-REQ/DSC-REQ messages. The SS specifies the SFID of a service flow using this parameter in a DSC-REQ message.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146],1</td>
<td>4</td>
<td>1–4 294 967 295</td>
<td>DSx-REQ</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSx-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSx-ACK</td>
</tr>
</tbody>
</table>
11.13.2 CID

The value of this field specifies the CID assigned by the BS to a service flow with a non-null AdmittedQosParamSet or ActiveQosParamSet. The 16-bit value of this field is used in BRs and in MAC PDU headers. This field shall be present in a BS-initiated DSA-REQ or DSC-REQ message related to establishing an admitted or active service flow. This field shall also be present in DSA-RSP and DSC-RSP messages related to the successful establishment of an admitted or active service flow.

Even though a service flow has been successfully admitted or activated (i.e., has an assigned CID) the SFID shall be used for subsequent DSx message signalling as it is the primary handle for a service flow. If a service flow is no longer admitted or active (via DSC-REQ), its CID may be reassigned by the BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].2</td>
<td>2</td>
<td>CID</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>

11.13.3 Service Class Name

The value of this field refers to a predefined BS service configuration to be used for this service flow.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].3</td>
<td>2 to 128</td>
<td>Null-terminated string of ASCII characters. The length of the string, including null-terminator may not exceed 128 bytes</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>

When the Service Class Name is used in a service flow encoding, it indicates that all the unspecified QoS parameters of the service flow need to be provided by the BS. It is up to the operator to synchronize the definition of Service Class Names in the BS.

11.13.4 QoS parameter set type

This parameter shall appear within every service flow encoding. It specifies the proper application of the QoS parameter set to the Provisioned set, the Admitted set, and/or the Active set. The QoS parameter set is a subset of the following parameter sets:

- Traffic Priority (11.13.5)
- Maximum Sustained Traffic Rate (11.13.6)
- Maximum Traffic Burst (11.13.7)
- Minimum Reserved Traffic Rate (11.13.8)
- Vendor-specific QoS parameters (11.13.9)
- Tolerated Jitter (11.13.12)
- Maximum Latency (11.13.13)
- Unsolicited Grant Interval (11.13.19)
- Unsolicited Polling Interval (11.13.20)

When two QoS parameter sets are the same, a multibit value of this parameter may be used to apply the QoS parameters to more than one set. A single message may contain multiple QoS parameter sets in separate
type 145/146 service flow encodings for the same service flow. This allows specification of the QoS parameter sets when their parameters are different. Non-QoS parameters shall appear only in the first service flow management encodings. Bit 0 is the LSB of the Value field.

If the QoS parameter set type is included in a service flow encoding for MBS service, the QoS Parameter Set may be omitted in the service flow encoding.

For every service flow that is preprovisioned and for every provisioned service flow added after SS initialization, there shall be a service flow encoding that specifies a ProvisionedQoSParamSet. This service flow encoding, or other service flow encoding(s), may also specify an Admitted and/or Active set.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].5</td>
<td>1</td>
<td>Bit 0: Provisioned Set</td>
<td>DSx-REQ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: Admitted Set</td>
<td>DSx-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: Active Set</td>
<td>DSx-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bits 3–7: Reserved</td>
<td></td>
</tr>
</tbody>
</table>

A BS shall handle a single update to each of the Active and Admitted QoS parameter sets. The ability to process multiple service flow encodings that specify the same QoS parameter set is not required and is left as a vendor-specific function. If a DSA/DSC contains multiple updates to a single QoS parameter set and the vendor does not support such updates, then the BS shall reply with CC 2 (reject-unrecognized-configuration-setting).

Table 608 lists values used in Dynamic Service messages.

<td>Perform admission control and activate this service flow, apply parameters to both Admitted and Active sets</td>
</tr>
</tbody>
</table>
11.13.5 Traffic Priority parameter

The value of this parameter specifies the priority assigned to a service flow. Given two service flows identical in all QoS parameters besides priority, the higher priority service flow should be given lower delay and higher buffering preference. For otherwise nonidentical service flows, the priority parameter should not take precedence over any conflicting service flow QoS parameter. The specific algorithm for enforcing this parameter is not mandated here.

For UL service flows, the BS shall use this parameter when determining precedence in request service and grant generation.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].6</td>
<td>1</td>
<td>0 to 7—Higher numbers indicate higher priority</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default 0</td>
<td></td>
</tr>
</tbody>
</table>

11.13.6 Maximum Sustained Traffic Rate parameter

This parameter defines the peak information rate of the service. The rate is expressed in bits per second and pertains to the SDUs at the input to the CS. Hence, this parameter does not include IEEE 802.16 MAC overhead such as MAC headers or CRCs. At the BS and SS, the service shall be policed to conform to this parameter, on the average, over time. If this parameter is omitted or set to zero, then there is no explicitly mandated maximum rate. This field specifies only a bound, not a guarantee that the rate is available.

The algorithm for measuring whether a flow exceeds its maximum sustained traffic rate is left to vendor differentiation and is outside the scope of this standard.

SDUs deemed to exceed the maximum sustained traffic rate may be, for instance, delayed or dropped according to the discretion of the vendor.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].7</td>
<td>4</td>
<td>Rate (in bits per second)</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.7 Maximum Traffic Burst parameter

This parameter defines the maximum burst size that shall be accommodated for the service. Since the physical speed of ingress/egress ports, the air interface, and the backhaul will, in general, be greater than the maximum sustained traffic rate parameter for a service, this parameter describes the maximum continuous burst the system should accommodate for the service, assuming the service is not currently using any of its available resources.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].8</td>
<td>4</td>
<td>Burst size (bytes)</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>
11.13.8 Minimum Reserved Traffic Rate parameter

This parameter specifies the minimum rate reserved for this service flow. The rate is expressed in bits per second and specifies the minimum amount of data to be transported on behalf of the service flow when averaged over time. The specified rate shall only be honored when sufficient data is available for scheduling.

The BS and SS shall be able to transport traffic up to its minimum reserved traffic rate. If less than the minimum reserved traffic rate is available for a service flow, the BS and SS may reallocate the excess reserved bandwidth for other purposes. The data for this parameter are measured at the input of the CS. The aggregate minimum reserved traffic rate of all service flows may exceed the amount of available bandwidth. If this parameter is omitted, then it defaults to a value of 0 bits per second (i.e., no bandwidth is reserved for the flow).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].9</td>
<td>4</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSx-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>REG-RSP</td>
</tr>
</tbody>
</table>

11.13.9 Vendor-specific QoS parameters

This allows vendors to encode vendor-specific QoS parameters. The Vendor ID shall be the first TLV embedded inside vendor-specific QoS parameters. If the first TLV inside vendor-specific QoS parameters is not a Vendor ID, then the TLV shall be discarded (see 11.1.6).

<table>
<thead>
<tr>

</tbody>
</table>

11.13.10 UL Grant Scheduling Type parameter

The value of this parameter specifies the UL grant scheduling type that shall be enabled for the associated UL service flow (see 6.3.5.2). If the parameter is omitted, BE is assumed.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>145.11</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSA-ACK</td>
</tr>
</tbody>
</table>

\textsuperscript{a}The specific implementation-dependent scheduling service type could be defined in a message of type 145.143 (vendor-specific QoS parameters).
11.13.11 Request/Transmission Policy parameter

The value of this parameter provides the capability to specify certain attributes for the associated service flow. These attributes include options for PDU formation and, for UL service flows, restrictions on the types of BR options that may be used. A value of 1 indicates that the action associated with the attribute bit overrides the default action.

<table>
<thead>

<td>Bit 3: If this bit is set to 1, the service flow shall not fragment data.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4: If this bit is set to 1, the service flow shall not suppress payload headers (CS parameter). If bit 4 is set to '0' and both the SS and the BS support PHS (according to 11.7.7.3), each SDU for this service flow shall be prefixed by a PHSI field, which may be set to 0 (see 5.2). If bit 4 is set to '1', none of the SDUs for this service flow shall have a PHSI field.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 5: If this bit is set to 1, the service flow shall not pack multiple SDUs (or fragments) into single MAC PDUs.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 6: If this bit is set to 1, the service flow shall not include CRC in the MAC PDU.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 7: If this bit is set to 1, the service flow shall not compress payload headers using ROHC. If bit 7 is set to '0' and both the SS and the BS support ROHC (according to 11.7.7.4), each SDU for this service flow shall be compressed using ROHC. If bit 7 is set to '1', none of the SDUs shall be compressed.</td>
<td></td>
</tr>
</tbody>
</table>

11.13.12 Tolerated Jitter parameter

This parameter defines the maximum delay variation (jitter) for the connection.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].13</td>
<td>4</td>
<td>Milliseconds</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>

11.13.13 Maximum Latency parameter

The value of this parameter specifies the maximum interval between the entry of a packet at the CS of the BS or the SS and the forwarding of the SDU to its Air Interface.
If defined, this parameter represents a service commitment (or admission criteria) at the BS or SS and shall be guaranteed by the BS or SS. A BS or SS does not have to meet this service commitment for service flows that exceed their minimum reserved rate.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].14</td>
<td>4</td>
<td>Milliseconds</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK, REG-RSP</td>
</tr>
</tbody>
</table>

### 11.13.14 Fixed-Length Versus Variable-Length SDU Indicator parameter

The value of this parameter specifies whether the SDUs on the service flow are fixed-length or variable-length. The parameter is used only if packing is on for the service flow. The default value is 0, i.e., variable-length SDUs.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].15</td>
<td>1</td>
<td>0: Variable-length SDUs</td>
<td>DSA-REQ, DSA-RSP, DSA-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Fixed-length SDUs</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default = 0</td>
<td></td>
</tr>
</tbody>
</table>

### 11.13.15 SDU Size parameter

The value of this parameter specifies the length of the SDU for a fixed-length SDU service flow. This parameter is used only if packing is on and the service flow is indicated as carrying fixed-length SDUs. The default value is 49 bytes, i.e., VC-switched ATM cells with PHS. The parameter is relevant for both ATM and packet CSs.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].16</td>
<td>1</td>
<td>Number of bytes. Default = 49.</td>
<td>DSA-REQ, DSA-RSP, DSA-ACK</td>
</tr>
</tbody>
</table>

### 11.13.16 Target SAID parameter

The target SAID parameter indicates the SAID onto which the service flow that is being set up shall be mapped.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].17</td>
<td>2</td>
<td>SAID onto which service flow is mapped</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
</tbody>
</table>
11.13.17 ARQ TLVs for ARQ-enabled connections

11.13.17.1 ARQ Enable TLV

This TLV indicates whether ARQ use is requested for the connection that is being setup. A value of 0 indicates that ARQ is not requested and a value of 1 indicates that ARQ is requested. The DSA-REQ shall contain the request to use ARQ or not. The DSA-RSP message shall contain the acceptance or rejection of the request. ARQ shall be enabled for this connection only if both sides report this TLV to be nonzero. The connection shall be accepted with ARQ if both sides report the TLV to be nonzero. If only one side reports the TLV to be nonzero, the connection shall either be rejected or accepted without ARQ.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].18</td>
<td>1</td>
<td>0 = ARQ Not Requested/Accepted</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = ARQ Requested/Accepted</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.17.2 ARQ_WINDOW_SIZE TLV

This parameter is negotiated upon connection setup or during operation. The DSA-REQ message shall contain the suggested value for this parameter. The DSA-RSP message shall contain the confirmation value or an alternate value for this parameter. The smaller of the two shall be used as the ARQ_WINDOW_SIZE TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].19</td>
<td>2</td>
<td>&gt; 0 and ≤ (ARQ_BSN_MODULUS/2)</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.17.3 ARQ_RETRY_TIMEOUT TLV

The ARQ_RETRY_TIMEOUT TLV should account for the transmitter and receiver processing delays and any other delays relevant to the system.

TRANSMITTER_DELAY: This is the total transmitter delay, including sending (e.g., MAC PDUs) and receiving (e.g., ARQ feedback) delays and other implementation dependent processing delays. If the transmitter is the BS, it may include other delays such as scheduling and propagation delay.

RECEIVER_DELAY: This is the total receiver delay, including receiving (e.g., MAC PDUs) and sending (e.g., ARQ feedback) delays and other implementation-dependent processing delays. If the receiver is the BS, it may include other delays such as scheduling and propagation delay.

The DSA-REQ message shall contain the values for these parameters, if the sender is requesting ARQ. The DSA-RSP message shall contain the values for these parameters if the sender of the corresponding DSA-REQ message requested ARQ and the sender of the DSA-RSP is accepting ARQ. When the DSA handshake is completed, each party shall calculate ARQ_RETRY_TIMEOUT TLV to be the sum of TRANSMITTER_DELAY and RECEIVER_DELAY.
11.13.17.4 ARQ_BLOCK_LIFETIME TLV

The DSA-REQ message shall contain the value of this parameter as defined by the parent service flow. If this parameter is set to 0, then the ARQ_BLOCK_LIFETIME TLV value shall be considered infinite.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].20 1.20</td>
<td>2</td>
<td>TRANSMITTER_DELAY 0–6553500 μs (100 μs granularity)</td>
<td>DSA-REQ, DSA-RSP REG-REQ, REG-RSP</td>
</tr>
<tr>
<td>[145/146].21 1.21</td>
<td>2</td>
<td>RECEIVER_DELAY 0–6553500 μs (100 μs granularity)</td>
<td>DSA-REQ, DSA-RSP REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.17.5 ARQ_SYNC_LOSS_TIMEOUT TLV

The BS shall set this parameter. The DSA-REQ or DSA-RSP messages shall contain the value of this parameter as set by the BS. If this parameter is set to 0, then the ARQ_SYNC_LOSS_TIMEOUT TLV value shall be considered infinite.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].22 1.22</td>
<td>2</td>
<td>0 = Infinite 1–6553500 μs (100 μs granularity)</td>
<td>DSA-REQ, DSA-RSP REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.17.6 ARQ_DELIVER_IN_ORDER TLV

The DSA-REQ message shall contain the value of this parameter. This TLV indicates whether data is to be delivered by the receiving MAC to its client application in the order in which the data was handed off to the originating MAC.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].24 1.24</td>
<td>1</td>
<td>0–Order of delivery is not preserved 1–Order of delivery is preserved</td>
<td>DSA-REQ, DSA-RSP REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

If this flag is not set, then the order of delivery is not preserved. If this flag is set (to 1), then the order of delivery is preserved.
11.13.17.7 **ARQ_RX_PURGE_TIMEOUT TLV**

The DSA-REQ message shall contain the value of this parameter as defined by the parent service flow. If this parameter is set to 0, then the ARQ_RX_PURGE_TIMEOUT TLV value shall be considered infinite.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].25</td>
<td>2</td>
<td>0 = Infinite</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0–6553500 μs (100 μs granularity)</td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.17.8 **ARQ_BLOCK_SIZE TLV**

This value of this parameter specifies the size of an ARQ block. This parameter shall be established by negotiation during the connection creation dialog.

The requester includes its desired minimum and maximum setting in the DSA-REQ/REG-REQ message. The receiver of the DSA-REQ/REG-REQ message shall select the value it prefers within the range of the two values, inclusive, in the DSA-REQ/REG-REQ message. This selected value is included in selected block size of the DSA-RSP/REG-RSP message.

Absence of the parameter during a DSA dialog shall indicate the originator of the message desires the maximum value.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].26</td>
<td>1</td>
<td>For DSA-REQ and REG-REQ:</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td></td>

<td>Bit 0–3: encoding for proposed minimum block size (M)</td>
<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4–7: encoding for proposed maximum block size (N)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>where:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The minimum block size is equal to 2^(M+4) and the maximum block size is equal to 2^(N+4), M ≤ 6, N ≤ 6, and M ≤ N</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>For DSA-RSP and REG-RSP:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 0–3: encoding for selected block size (P)</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4–7: set to 0</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>where:</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The selected block size is equal to 2^(P+4), P ≤ 6 and M ≤ N</td>
<td></td>
</tr>
</tbody>
</table>

11.13.17.9 **RECEIVER_ARQ_ACK_PROCESSING_TIME TLV**

The BS or SS may provide this parameter. The DSA-REQ and DSA-RSP messages may contain the value of this parameter. This optional parameter indicates the number of ms required by the ARQ receiver to process the received ARQ blocks and provide a valid ACK or NAK. This does not mean that the receiver would actually transmit an ACK or NAK after this time, but rather it can be optionally used by the transmitter that

---

Copyright © 2009 IEEE. All rights reserved.
receives an ACK bit-map to determine which bits are retransmissions of historical NAKs or ACKs, that are not based on newly received ARQ blocks.

### 11.13.18 CS-specific service flow encodings

#### 11.13.18.1 CS Specification parameter

This parameter specifies the CS that the connection being set up shall use.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].27</td>
<td>1</td>
<td>0–255</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td>[145/146].27</td>
<td>1</td>
<td></td>
<td>REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

#### 11.13.18.2 CS parameter encoding rules

Each CS defines a set of parameters that are encoded within a subindex under the “cst” values listed below. In the cases of IP over IEEE 802.3, the relevant IP and IEEE 802.3 parameters shall be included in the DSx-REQ message.

<table>
<thead>
<tr>
<th>cst</th>
<th>CS</th>
</tr>
</thead>
<tbody>
<tr>
<td>99</td>
<td>ATM</td>
</tr>
<tr>
<td>100</td>
<td>Packet, IPv4</td>
</tr>
<tr>
<td>101</td>
<td>Packet, IPv6</td>
</tr>
<tr>
<td>102</td>
<td>Packet, IEEE 802.3/Ethernet</td>
</tr>
<tr>
<td>103</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

^Classifiers for IEEE 802.1Q VLAN tags may be applied to service flows of this CS type.

^SDUs for service flows of this CS type may carry either IPv4 or IPv6 in the header-compressed payload.
11.13.18.3 Packet CS encodings for configuration and MAC messaging

The following TLV encoded parameters shall be used in Dynamic Service messages. The CS specific type is denoted in the tables in the following subclauses by the variable “cst,” which takes its value from the table in 11.13.18.2 (e.g., 100, 101, ...) depending upon the exact packet CS used for the service.

11.13.18.3.1 QoS-related encodings

The following TLV encodings shall be used in registration messages and Dynamic Service messages to encode parameters for packet classification and scheduling.

The following configuration settings shall be supported by all SSs that are compliant with this specification.

11.13.18.3.2 Classifier DSC Action

When received in a DSC-REQ, this indicates the action to be taken with this classifier.

11.13.18.3.3 Packet Classification Rule parameter

This compound parameter contains the parameters of the classification rule. All parameters pertaining to a specific classification rule shall be included in the same Packet Classification Rule compound parameter. A
packet classification rule containing only the classification rule index (11.13.18.3.3.14) and with no other classification parameters matches all packets entering the convergence sublayer.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3</td>
<td>variable</td>
<td>Compound</td>
</tr>
</tbody>
</table>

### 11.13.18.3.3.1 Classification Rule Priority field

The value of this field specifies the priority for the classification rule, which is used for determining the order of the classification rule. A higher value indicates higher priority.

Classification rule may have priorities in the range 0–255 with the default value being 0.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.1</td>
<td>1</td>
<td>0–255</td>
</tr>
</tbody>
</table>

### 11.13.18.3.3.2 Reserved

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.2</td>
<td>3</td>
<td>Reserved (deprecated by [145/146].cst.3.20)</td>
</tr>
</tbody>
</table>

### 11.13.18.3.3.3 Protocol field

The value of this field specifies a matching value for the IP Protocol field. For IPv6 (IETF RFC 2460), this refers to next header entry in the last header of the IP header chain. The encoding of the value field is that defined by the IANA document “Protocol Numbers.” If this parameter is omitted, then comparison of the IP Header Protocol field for this entry is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.3</td>
<td>1</td>
<td>protocol</td>
</tr>
</tbody>
</table>

### 11.13.18.3.3.4 IP Masked Source Address parameter

This parameter specifies an IP source address (designated “src”) and its corresponding address mask (designated “smask”). An IP packet with IP source address “ip-src” matches this parameter if src = (ip-src AND smask). If this parameter is omitted, then comparison of the IP packet source address for this entry is irrelevant.
11.13.18.3.3.5 IP Masked Destination Address parameter

This parameter specifies an IP destination address (designated “dst”) and its corresponding address mask (designated “dmask”). An IP packet with IP destination address “ip-dst” matches this parameter if dst = (ip-dst AND dmask). If this parameter is omitted, then comparison of the IP packet destination address for this entry is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.5</td>
<td>8 (IPv4) or 32 (IPv6)</td>
<td>dst, dmask</td>
</tr>
</tbody>
</table>

11.13.18.3.3.6 Protocol Source Port Range field

The value of this field specifies a range of protocol source port values. Classification rules with port numbers are protocol-specific; i.e., a rule on port numbers without a protocol specification shall not be defined. An IP packet with protocol port value “src-port” matches this parameter if src-port is greater than or equal to sportlow and src-port is less than or equal to sporthigh. If this parameter is omitted, the protocol source port is irrelevant. This parameter is irrelevant for protocols without port numbers.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.6</td>
<td>4</td>
<td>sportlow, sporthigh</td>
</tr>
</tbody>
</table>

11.13.18.3.3.7 Protocol Destination Port Range field

The value of this field specifies a range of protocol destination port values. Classification rules with port numbers are protocol-specific; i.e., a rule on port numbers without a protocol specification shall not be defined. An IP packet with protocol port value “dst-port” matches this parameter if dst-port is greater than or equal to dportlow and dst-port is less than or equal to dporthigh. If this parameter is omitted the protocol destination port is irrelevant. This parameter is irrelevant for protocols without port numbers.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.7</td>
<td>4</td>
<td>dportlow, dporthigh</td>
</tr>
</tbody>
</table>
11.13.18.3.3.8 IEEE 802.3/Ethernet Destination MAC Address parameter

This parameter specifies a MAC destination address (designated “dst”) and its corresponding address mask (designated “msk”). An IEEE 802.3/Ethernet packet with MAC destination address “etherdst” corresponds to this parameter if dst = (etherdst AND msk). If this parameter is omitted, then comparison of the IEEE 802.3/Ethernet destination MAC address for this entry is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.8</td>
<td>12</td>
<td>dst, msk</td>
</tr>
</tbody>
</table>

11.13.18.3.3.9 IEEE 802.3/Ethernet Source MAC Address parameter

This parameter specifies a MAC source address (designated “src”) and its corresponding address mask (designated “msk”). An IEEE 802.3/Ethernet packet with MAC source address “ethersrc” corresponds to this parameter if src = (ethersrc AND msk). If this parameter is omitted, then comparison of the IEEE 802.3/Ethernet source MAC address for this entry is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.9</td>
<td>12</td>
<td>src, msk</td>
</tr>
</tbody>
</table>

11.13.18.3.3.10 Ethertype/IEEE 802.2 SAP

The format of the Layer 3 protocol ID in the Ethernet packet is indicated by type, eprot1, and eprot2 as follows:

— If type = 0, the rule does not use the Layer 3 protocol type as a matching criteria. If type = 0, eprot1, eprot2 are ignored when considering whether a packet matches the current rule.
— If type = 1, the rule applies only to SDUs that contain an Ethertype value. Ethertype values are contained in packets using the DEC-Intel-Xerox (DIX) encapsulation or the Sub-Network Access Protocol (SNAP) encapsulation (IEEE 802.2, IETF RFC 1042) format. If type = 1, then eprot1, eprot2 gives the 16 bit value of the Ethertype that the packet shall match in order to match the rule.
— If type = 2, the rule applies only to SDUs using the IEEE 802.2 encapsulation format with a Destination Service (DSAP) other than 0xAA (which is reserved for SNAP). If type = 2, the lower 8 bits of the eprot1, eprot2 shall match the DSAP byte of the packet in order to match the rule.

If the Ethernet SDU contains an IEEE 802.1D and IEEE 802.1Q tag header (i.e., Ethertype 0x8100), this object applies to the embedded Ethertype field within the IEEE 802.1D and IEEE 802.1Q header.

Other values of type are reserved. If this TLV is omitted, then comparison of either the Ethertype or IEEE 802.2 DSAP for this rule is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.10</td>
<td>3</td>
<td>type, eprot1, eprot2</td>
</tr>
</tbody>
</table>
11.13.18.3.3.11 IEEE 802.1D User Priority field

The values of this field specify the matching parameters for the IEEE 802.1D user_priority bits. An Ethernet packet with IEEE 802.1D user_priority value “priority” matches these parameters if priority is greater than or equal to pri-low and priority is less than or equal to pri-high. If this field is omitted, then comparison of the IEEE 802.1D user_priority bits for this entry is irrelevant.

If this parameter is specified for an entry, then Ethernet packets without IEEE 802.1Q encapsulation shall NOT match this entry. If this parameter is specified for an entry on an SS that does not support forwarding of IEEE 802.1Q encapsulated traffic, then this entry shall not be used for any traffic.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.11</td>
<td>2</td>
<td>pri-low, pri-high</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid range: 0–7 for pri-low and pri-high</td>
</tr>
</tbody>
</table>

11.13.18.3.3.12 IEEE 802.1Q VLAN ID field

The value of this field specifies the matching value for the IEEE 802.1Q vlan_id bits. Only the first (i.e., leftmost) 12 bits of the specified vlan_id field are significant; the final four bits shall be ignored for comparison. If this field is omitted, then comparison of the IEEE 802.1Q vlan_id bits for this entry is irrelevant.

If this parameter is specified for an entry, then Ethernet packets without IEEE 802.1Q encapsulation shall not match this entry. If this parameter is specified for an entry on an SS that does not support forwarding of IEEE 802.1Q encapsulated traffic, then this entry shall not be used for any traffic.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.12</td>
<td>2</td>
<td>vlan_id1, vlan_id2</td>
</tr>
</tbody>
</table>

11.13.18.3.3.13 Associated PHSI field

The Associated PHSI field has a value between 1 and 255, which shall mirror the PHSI value of a PHS rule. Packets matching the Packet Classification Rule containing the Associated PHSI parameter shall undergo PHS according to the corresponding PHS rule.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.13</td>
<td>1</td>
<td>Index value</td>
</tr>
</tbody>
</table>
11.13.18.3.3.14 Packet Classification Rule Index field

The Packet Classification Rule Index field identifies a packet classification rule. The packet classification rule index is unique per service flow. The BS shall assign all Packet Classifier Rule Index values.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.14</td>
<td>2</td>
<td>Packet Classification Rule Index</td>
</tr>
</tbody>
</table>

11.13.18.3.3.15 Vendor-specific classification parameters

This allows vendors to encode vendor-specific classification rule parameters. The Vendor ID shall be the first TLV embedded inside vendor-specific classification rule parameters. If the first TLV inside vendor-specific classification rule parameters is not a Vendor ID, then the TLV shall be discarded (see 11.1.6).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.143</td>
<td>variable</td>
<td>Compound</td>
</tr>
</tbody>
</table>

11.13.18.3.3.16 IPv6 Flow Label field

The value of this field specifies a matching value for the IPv6 Flow Label field. As the Flow Label field has a length of 20 bits, the first 4 bits of the most significant byte shall be set to 0x0 and disregarded.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.15</td>
<td>3</td>
<td>Flow Label</td>
</tr>
</tbody>
</table>

11.13.18.3.3.17 Classification Action Rule

The value of this field specifies an action associate with the classifier rule.

If this classification action rule exists, its action shall be applied on the packets that match this classifier rule.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.19</td>
<td>1</td>
<td>See below</td>
</tr>
</tbody>
</table>

Bit 0:
0 = none.
1 = Discard packet

Bit 1–7: Reserved.
11.13.18.3.3.18 IP Type of Service

The value of this TLV specifies the matching parameters for the IP Type of Service (TOS) octet. The 6 MSBs shall be set to a Differentiated Service Codepoint (DSCP), as specified by RFC 2474, and the 2 LSBs shall be reserved and set to 0b00. The DSCP values are managed by IANA under the Differentiated Services Field Codepoints registry. If this field is omitted, then comparison of the IP packet TOS octet for this entry is irrelevant.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.3.20</td>
<td>1</td>
<td>Bit 0–Bit 1: reserved. Shall be set to 0b00</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2–Bit 7: DSCP value</td>
</tr>
</tbody>
</table>

11.13.18.3.4 PHS DSC Action field

When received in a DSC-REQ, this field indicates the action that shall be taken with this PHS byte string.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.4</td>
<td>1</td>
<td>0: Add PHS Rule</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Set PHS Rule</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2: Delete PHS Rule</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3: Delete all PHS Rules</td>
</tr>
</tbody>
</table>

The Set PHS Rule command is used to add the specific TLVs for an undefined PHS rule. It shall NOT be used to modify existing TLVs.

When deleting all PHS Rules, any corresponding PHSI shall be ignored.

An attempt to add a PHS Rule that already exists is an error condition.

11.13.18.3.5 PHS Rule field

This field defines the parameters associated with a PHS Rule.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6</td>
<td>n</td>
<td></td>
</tr>
</tbody>
</table>

11.13.18.3.5.1 PHSI field

The PHSI has a value between 1 and 255, which uniquely references the suppressed byte string. The index is unique per service flow.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.1</td>
<td>1</td>
<td>Index value</td>
</tr>
</tbody>
</table>
11.13.18.3.5.2 PHSF field

The PHSF is a string of bytes containing the header information to be suppressed by the sending CS and reconstructed by the receiving CS. The most significant byte of the string corresponds to the first byte of the CS-SDU.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.2</td>
<td>n</td>
<td>String of bytes suppressed</td>
</tr>
</tbody>
</table>

The length $n$ shall always be the same as the value for PHSS.

11.13.18.3.5.3 PHSM field

The value of this field is used to interpret the values in the PHSF. It is used at both the sending and receiving entities on the link. The PHSM allows fields, such as sequence numbers or checksums (which vary in value), to be excluded from suppression with the constant bytes around them suppressed.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.3</td>
<td>n</td>
<td>Bit 0:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Don’t suppress first byte of the suppression field</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Suppress first byte of the suppression field</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Don’t suppress second byte of the suppression field</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Suppress second byte of the suppression field</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit x:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Don’t suppress $(x + 1)$ byte of the suppression field</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Suppress $(x + 1)$ byte of the suppression field</td>
</tr>
</tbody>
</table>

The length $n$ is ceiling (PHSS/8). Bit 0 is the MSB of the Value field. The value of each sequential bit in the PHSM is an attribute for the corresponding sequential byte in the PHSF.

If the bit value is a 1, the sending entity should suppress the byte, and the receiving entity shall restore the byte from its cached PHSF. If the bit value is a 0, the sending entity shall not suppress the byte, and the receiving entity shall restore the byte by using the next byte in the packet.

If this TLV is not included, the default is to suppress all bytes.

11.13.18.3.5.4 PHSS field

The value of this field is the total number of bytes in the header to be suppressed and then restored in a service flow that uses PHS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.4</td>
<td>1</td>
<td>Number of bytes in the suppression string</td>
</tr>
</tbody>
</table>
For all packets that get classified and assigned to a service flow with PHS enabled, suppression shall be performed over the specified number of bytes as indicated by the PHSS and according to the PHSM. A PHS Rule shall only be used if it has been completely defined by the PHSS TLV. The range of valid values for PHSS is 1–255.

11.13.18.3.5.5 PHSV field

The value of this field indicates to the sending entity whether the packet header contents are to be verified prior to performing suppression. If PHSV is enabled, the sender shall compare the bytes in the packet header with the bytes in the PHSF that are to be suppressed as indicated by the PHSM.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.5</td>
<td>1</td>
<td>0: Verify</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Don’t verify</td>
</tr>
</tbody>
</table>

If this TLV is not included, the default is to verify. Only the sender shall verify suppressed bytes. If verification fails, the payload header shall NOT be suppressed.

11.13.18.3.5.6 Vendor-specific PHS parameters

This allows vendors to encode vendor-specific PHS parameters. The Vendor ID shall be the first TLV embedded inside vendor-specific PHS parameters. If the first TLV inside vendor-specific PHS parameters is not a Vendor ID, then the TLV shall be discarded.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.6.143</td>
<td>variable</td>
<td>Compound</td>
</tr>
</tbody>
</table>

11.13.18.4 ATM CS encodings for configuration and MAC messaging

The TLV encodings listed in 11.13.18.4.1 through 11.13.18.4.3 shall be used in the configuration file, in SS registration requests (when applicable), and in Dynamic Service messages (when applicable). All ATM specific TLVs are prefixed to begin with a Type value of [145/146].99.

11.13.18.4.1 ATM Switching Encoding field

This field defines the switching methodology for the service. If the field = 0, at least one VPI/VCI Classifier pair shall be defined for classifying the service. If the field = 1, exactly one VPI Classifier and zero or one VCI Classifier shall be specified for classifying the service. If the field = 2, exactly one VPI Classifier and one VCI Classifier shall be defined for classifying the service. If the field = 0, PHS is not allowed and the SDU size TLV shall equal 52. If the field = 1 and PHS is on for the service, the SDU size TLV shall equal 51; otherwise it shall be set equal to 52. If the field = 2 and PHS is on for the service, the SDU size TLV shall equal 49; otherwise it shall be set equal to 52.
11.13.18.4.2 ATM Classifier TLV field

This field defines an ATM classifier. It is a compound TLV used to describe the VPI and associated VCIs for ATM classification.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
</table>
| [145/146].99.1 | 1 | 0: No switching methodology applied  
1: VP switching  
2: VC switching |

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].99.2</td>
<td>variable</td>
<td>Compound</td>
</tr>
</tbody>
</table>

It shall have the following form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATM Classifier ID</td>
<td>Always present</td>
</tr>
<tr>
<td>VPI Classifier</td>
<td>Always present except for DSC Change action deleting classifier</td>
</tr>
<tr>
<td>VCI Classification</td>
<td>0 or more instances (number apparent from ATM Classifier length field) if VPI Classifier is present</td>
</tr>
</tbody>
</table>

11.13.18.4.2.1 VPI Classifier field

This field defines the VPI on which to classify ATM cells for the service flow.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].99.2.1</td>
<td>2</td>
<td>8-bit or 12-bit VPI field value</td>
</tr>
</tbody>
</table>

11.13.18.4.2.2 VCI Classification field

This field defines the VCI on which to classify ATM cells for the service flow.

This TLV shall immediately follow the VPI TLV with which it is associated.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].99.2.2</td>
<td>2</td>
<td>16-bit VCI field value</td>
</tr>
</tbody>
</table>
11.13.18.4.2.3 ATM Classifier ID field

This field is used to identify an ATM classifier.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].99.2.3</td>
<td>2</td>
<td>16-bit classifier ID</td>
</tr>
</tbody>
</table>

11.13.18.4.3 ATM Classifier DSC Action field

When received in a DSC-REQ message, this field indicates the action to be taken on a classifier. If the action TLV is Add or Replace, the action is followed by a complete ATM Classifier compound TLV. If the action is delete, the action TLV is followed by the ATM Classifier compound TLV composed only of the ATM Classifier ID TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].99.3</td>
<td>1</td>
<td>0: DSC Add Classifier</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: DSC Replace Classifier</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2: DSC Delete Classifier</td>
</tr>
</tbody>
</table>

11.13.18.5 GPCS CS encodings for configuration and MAC messaging

11.13.18.5.1 GPCS PROTOCOL_TYPE encoding

The GPCS_PROTOCOL_TYPE TLV indicates the type of protocol layer that sits above the GPCS service. This allows the remote end to be able to correctly parse the payload contents of GPCS PDUs.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].cst.7.1</td>
<td>2</td>
<td>Two byte upper layer protocol number</td>
<td>DSx-REQ, DSx-RSP</td>
</tr>
</tbody>
</table>
The value field is 16 bits and its encoding is defined in the following table.

<table>
<thead>
<tr>
<th>GPCS_PROTOCOL_TYPE</th>
<th>Layer above GPCS</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0000</td>
<td>Ethernet MAC</td>
<td>An upper layer that sinks and sources Ethernet formatted frames consistent with those used in the Ethernet CS.</td>
</tr>
<tr>
<td>0x0001</td>
<td>MPLS</td>
<td>Raw MPLS packets with MPLS label and payload.</td>
</tr>
<tr>
<td>0x0002</td>
<td>PPP</td>
<td>The Point to Point Protocol.</td>
</tr>
<tr>
<td>0x0003</td>
<td>Raw IP</td>
<td>Raw IP packets. This is necessary for a point to point IP link since ARP cannot be supported. Note that the first byte of every IP packet allows the distinction between IPv4, IPv6 and ROHC (RFC 3095) IP packets so these protocols may be multiplexed over the same GPCS connection.</td>
</tr>
<tr>
<td>0x0004</td>
<td>ECRTP</td>
<td>ECRTP (Enhanced Compressed RTP) encapsulated packets (IETF RFC 3545).</td>
</tr>
<tr>
<td>0x0005-0xFFFF</td>
<td>Reserved</td>
<td>Reserved for future additional encodings. These encodings shall not be used.</td>
</tr>
<tr>
<td>0xF000-0xFFFF</td>
<td>Reserved Playpen</td>
<td>These encodings shall not be used in deployed equipment and are reserved for experimental use.</td>
</tr>
</tbody>
</table>

For a connection using Generic Packet CS, this TLV shall be used to indicate the protocol carried over the connection. For other packet CS types, GPCS_PROTOCOL_TYPE is not used.

11.13.19 Unsolicited Grant Interval parameter

The value of this parameter specifies the nominal interval between successive data grant opportunities for this service flow. The ideal schedule for enforcing this parameter is defined by a reference time \( t_0 \), with the desired transmission time \( t_i = t_0 + i \times \text{interval} \). The actual grant time, \( t'_i \), shall be in the range \( t_i \leq t'_i \leq t_i + \text{jitter} \), where interval is the value specified with this TLV, and jitter is the Tolerated Jitter.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145].40</td>
<td>2</td>
<td>Milliseconds</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-RSP</td>
</tr>
</tbody>
</table>

11.13.20 Unsolicited Polling Interval parameter

The value of this parameter specifies the maximal nominal interval between successive polling grants opportunities for this Service Flow. The ideal schedule for enforcing this parameter is defined by a reference time \( t_0 \), with the desired polling time \( t_i = t_{(i-1)} + \text{interval} \).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145].41</td>
<td>2</td>
<td>Milliseconds</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-REP</td>
</tr>
</tbody>
</table>
11.13.21 FSN size TLV

This TLV indicates the size of the FSN for the connection that is being setup. A value of 0 indicates that FSN is 3-bit long and a value of 1 indicates that FSN is 11-bit long.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].38</td>
<td>1</td>
<td>0: 3-bit FSN</td>
<td>DSA-REQ, DSA-RSP, DSA-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: 11-bit FSN</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default = 1</td>
<td></td>
</tr>
</tbody>
</table>

11.13.22 MBS service TLV

This TLV indicates whether the MBS service is being requested or provided for the connection that is being setup. A value of 1 indicates that an MBS service limited to the serving BS is being requested and a value of 2 indicates multi-BS-MBS with macro-diversity is being requested. A value of 3 indicates that multi-MBS without macro-diversity is being requested or provided. If MS or BS wants to initiate MBS service, DSA-REQ with MBS service TLV shall be used. The DSA-RSP message shall contain the acceptance or rejection of request and if there is no available MBS, MBS service value shall be set to 0.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].4</td>
<td>1</td>
<td>0: No available MBS</td>
<td>DSA-REQ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: MBS in Serving BS Only</td>
<td>DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2: MBS in a multi-BS Zone supporting macro-diversity</td>
<td>DSA-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3: MBS in a multi-BS Zone not supporting macro-diversity</td>
<td>DSC-REQ,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4-255: Reserved</td>
<td>DSC-RSP</td>
</tr>
</tbody>
</table>

The MBS service TLV shall only be updated in conjunction with an inter-MBS-zone transition.

The BS shall not establish an MBS service type that is incompatible with MS capabilities (refer to 11.7.24) or which is not supported at the BS.

11.13.23 Global Service Class Name field

The value of this field refers to a predefined BS service configuration to be used for this service flow. The Global Service Class Name itself contains coded references to extensible tables defining QoS Parameters.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].35</td>
<td>variable</td>
<td>Variable: Refer to Table 186 of 6.3.14.4.1</td>
<td>DSx-REQ</td>
</tr>
<tr>
<td></td>
<td>(see 6.3.14.4.1)</td>
<td></td>
<td>DSx-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSx-ACK</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>RNG-RSP</td>
</tr>
</tbody>
</table>

When the Global Service Class Name is used in a service flow encoding, it indicates that all the unspecified QoS Parameters of the service flow need to be provided by the BS. Global Service Class Names are by definition synchronized among all BS.
11.13.24 Type of Data Delivery Services parameter

The value of this parameter specifies type of Data Delivery Service as defined in 6.3.19. This TLV shall apply only to DL Service Flows.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[146].29</td>
<td>1</td>
<td>0: Unsolicited Grant Service</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1: Real-Time Variable Rate Service</td>
<td>REG-REQ, REG-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2: Non-Real-Time Variable Rate Service</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>3: Best Effort Service</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>4: Extended Real-Time Variable Rate Service</td>
<td></td>
</tr>
</tbody>
</table>

11.13.25 SDU Inter-Arrival Interval parameter

This parameter specifies nominal interval between consequent SDU arrivals as measured at MAC SAP.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].30</td>
<td>2</td>
<td>SDU inter-arrival interval in the resolution of 0.5 ms</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-RSP, REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.26 Time Base parameter

This parameter specifies time base for rate measurement as defined in 6.3.19.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].31</td>
<td>2</td>
<td>Time base in milliseconds</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-RSP, REG-REQ, REG-RSP</td>
</tr>
</tbody>
</table>

11.13.27 MBS Zone Identifier Assignment parameter

The DSA-REQ/RSP message may contain the value of this parameter to specify a MBS Zone identifier. This parameter indicates a MBS zone through which the connection or virtual connection for the associated service flow is valid.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].33</td>
<td>1</td>
<td>MBS zone identifier (bits 6 through 0 are the MBS Zone Identifier, bit 7 is set to 0)</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-RSP</td>
</tr>
</tbody>
</table>
11.13.28 Paging Preference parameter

This parameter specifies whether a service flow may generate paging.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>DSX</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].32</td>
<td>1</td>
<td>0: No paging generation 1: Paging generation</td>
<td>DSx-REQ, DSx-RSP, DSx-ACK</td>
</tr>
</tbody>
</table>

11.13.29 SN Feedback Enabled field

The SN Feedback Enabled field indicates whether SN feedback is enabled for the given connection. A value of 0 indicates that SN feedback is not enabled. A value of 1 indicates that SN feedback is enabled.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].37</td>
<td>1</td>
<td>0: SN feedback is disabled (default) 1: SN feedback is enabled</td>
<td>DSA-REQ, DSA-RSP, DSC-REQ, DSC-REP</td>
</tr>
</tbody>
</table>

11.13.30 HARQ Service Flows field

The HARQ Service Flows field specifies whether the connection uses HARQ.

The relevant connections of this parameter when it appears in SBC-REQ/RSP messages are Basic, Primary, and Secondary CIDs. HARQ is enabled independently in the UL and DL directions. For the UL management connections, this TLV is encapsulated in the compound UL service flow TLV Type = 145. For the DL management connections, this TLV is encapsulated in the compound DL service flow TLV Type = 146.

The MS and BS shall transmit MAC PDUs on transport connections for which HARQ has been enabled in HARQ subbursts only, and shall transmit MAC PDUs on transport connections for which HARQ has not been enabled in non-HARQ bursts only. Unless HARQ has been enabled for the management connections, the BS shall transmit MAC management PDUs in non-HARQ bursts only. The MS should not discard a MAC management PDU received in a non-HARQ burst, even if HARQ has been enabled for the management connection. The BS should not discard a MAC management PDU without payload received in a HARQ allocation irrespectively of whether HARQ has been enabled for the management connection. The BS should not discard a MAC management PDU received in a non-HARQ allocation irrespectively of whether HARQ has been enabled for the management connection.

A non-HARQ burst is a burst for which the receiver cannot expect a HARQ retransmission.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].44</td>
<td>1</td>
<td>0: Non-HARQ (default) 1: HARQ connection</td>
<td>DSA-REQ, DSA-RSP, SBC-REQ, SBC-RSP</td>
</tr>
</tbody>
</table>
11.13.31 CID Allocation for Active BSs field

The value of this field specifies a list of CIDs assigned by active BSs in the diversity set except for the anchor BS for the service flow with non-null AdmittedQoSParamSet or ActiveQoSParamSet. There is one CID per active BS and the CID is used when the active BS becomes the anchor BS. If CID assignment is sent for each active BS in MOB_BSHO-RSP and MOB_BSHO-REQ messages, the DSx messages shall contain CID allocation for Active BSs. The CID for anchor BS is defined by 11.13.2. The value of (Num of active BS) is used to calculate length is the number of BSs in the diversity set.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146],39</td>
<td>variable</td>
<td>List of CIDs for the active BSs. Starting from the first byte, every 2 bytes contains one CID value per active BS. CIDs are listed based on the TEMP_BS_ID of the active BS. The BS. The TEMP_BS_IDs are sorted in an ascending order.</td>
<td>DSA-REQ/RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSC-REQ/RSP</td>
</tr>
</tbody>
</table>

11.13.32 Authorization Token field

The value of the Authorization Token field specifies an authorization token that may be used when MS creates or modifies a service flow by sending DSA-REQ or DSC-REQ message. An authorization token identifies a session and its QoS parameters, and is used for authorizing the QoS for one or more IP flows generated by higher level service creation/modification procedures. The token is provided to the MS by the higher level service through some mechanism that is outside the scope of this specification. The MS shall include the token in this TLV exactly as received from the higher level service and shall treat the token as an opaque octet string whose meaning is of significance only to those higher level services. The field should not be included in the DSA-REQ or DSC-REQ messages that are sent by BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146],45</td>
<td>variable</td>
<td>Authorization token that is used for authorizing the QoS for one or service flows generated by MS-initiated higher level service flow creation or modification procedures.</td>
<td>DSA-REQ</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>DSC-REQ</td>
</tr>
</tbody>
</table>

11.13.33 HARQ Channel Mapping TLV

This TLV is valid only for HARQ-enabled connection. It specifies the set of HARQ channels for carrying data on this connection acceptable to the sender of this TLV. A HARQ channel may be shared by more than one connection.

The absence of this TLV in any of the REQ or RSP messages relevant for the connection means that the sender of the message accepts that all HARQ channels from '0' up to the number of HARQ channels supported may be used by this connection. Only the HARQ channels commonly accepted for the connection by the MS and the BS may be used.

The relevance of this parameter when it appears in the SBC-REQ/RSP messages is the Basic, Primary, and Secondary connections. HARQ Channel mapping is enabled independently in the UL and DL directions. For the UL management connections, this TLV is encapsulated in the compound UL service flow TLV Type =
For the DL management connections, this TLV is encapsulated in the compound DL service flow TLV Type = 146.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].46</td>
<td>variable</td>
<td>HARQ channel index (1 byte each)</td>
<td>DSA-REQ, DSA-RSP, SBC-REQ, SBC-RSP</td>
</tr>
</tbody>
</table>

### 11.13.34 PDU SN Extended Subheader for HARQ Reordering TLV

This TLV is valid only in HARQ-enabled connection. It specifies whether PDU SN extended subheader should be applied by the transmitter on every PDU on this connection. This SN may be used by the receiver to ensure PDU ordering.

This counter should start at 0 and should be reset after HO/FBSS operations.

The relevance connections of this parameter when appears in SBC-REQ/RSP messages are Basic, Primary, and Secondary CIDs (each should have its own PDU numbering). PDU SNs are enabled independently in the UL and DL directions. For the UL management connections, this TLV is encapsulated in the compound UL service flow TLV Type = 145. For the DL management connections, this TLV is encapsulated in the compound DL service flow TLV Type = 146.

Value of 0 in either of the messages means the endpoint does not support the PDU SN number for the specific connection. If both endpoints support PDU SN for the connection, the larger SN number should be chosen.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].42</td>
<td>1</td>
<td>0: No support for PDU SN in this connection (default). 1: PDU SN (short) extended SH. 2: PDU SN (long) extended SH. 3–255: Reserved.</td>
<td>DSA-REQ, DSA-RSP, SBC-REQ, SBC-RSP</td>
</tr>
</tbody>
</table>

### 11.13.35 MBS contents IDs

MBS contents IDs values shall be composed of 2 byte-long MBS Contents IDs to distinguish the logical MBS connection for each MBS contents. MBS Contents IDs is vendor-specific and dependent on application-level implementation and is not specified in this standard.

A 1 byte-long Logical Channel ID, which pairs with Multicast CID in Extended_MBS_DATA_IE, is allocated to each 2 byte-long MBS Contents IDs in order that it is included in MBS content IDs value. For example, Logical Channel ID 0 is allocated to MBS Contents ID(0), Logical Channel ID 1 is allocated to MBS Contents ID(1) and so on. Logical Channel ID is used for MS to discriminate the MBS message in MBS data burst.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>

</table>
11.13.36 ROHC Parameter

This compound parameter contains the ROHC channel parameters. All parameters pertaining to a specific ROHC channel shall be negotiated through a single ROHC Parameter compound TLV. Refer to RFC3095, 5.1.1, for the definition of these parameters.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].47</td>
<td>variable</td>
<td>Compound</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
</tbody>
</table>

11.13.36.1 ROHC Max Context ID

This TLV contains the ROHC parameter MAX_CID. Both entities may include this TLV. The responder shall not send a value that is larger than the value sent by the requestor. If the requestor omits this parameter, the responder shall include this parameter. If only one entity includes this parameter, then that value is the negotiated value. Otherwise, the negotiated value is the lesser of the two values sent by the entities.

<table>
<thead>
<tr>
<th>Type</th>

</tr>
</tbody>
</table>

11.13.36.2 Large Context IDs

This TLV contains the ROHC parameter LARGE_CIDS. Both entities may include this TLV. The responder shall not send a value that is larger than the value sent by the requestor. If the requestor omits this parameter, the responder shall include this parameter. If only one entity includes this parameter, then that value is the negotiated value. Otherwise, the negotiated value is the lesser of the two values sent by the entities.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>[145/146].47.2</td>
<td>1</td>
<td>0: FALSE (Small Context ID) 1: TRUE (Large Context ID) 2–255: Reserved</td>
<td>DSA-REQ, DSA-RSP</td>
</tr>
</tbody>
</table>

11.13.36.3 ROHC Profiles

This TLV contains the ROHC parameter PROFILES. Both entities may include this TLV. The responder shall not include profiles that are not included by the requestor. If the requestor omits this parameter, the responder shall include this parameter. If only one entity includes this parameter, then that set is the negotiated value. Otherwise, the negotiated set of profiles is the smallest set of two the sets sent by entities.

11.13.36.4 ROHC Feedback Channel

This TLV contains the ROHC parameter FEEDBACK_FOR. The value of this parameter is an SFID. If provided, this parameter indicates to which service flow the FEEDBACK_FOR channel is mapped. Only the BS may send this TLV containing a non-zero value. The MS indicates a request for a FEEDBACK_FOR channel.
channel by omitting this TLV. If the BS receives a request for a FEEDBACK_FOR channel, it may respond with a new DSC transaction containing a proper value.

<table>
<thead>
<tr>
<th>Type</th>

<td>DSA-REQ, DSA-RSP</td>
</tr>
</tbody>
</table>

### 11.13.36.5 ROHC MRRU

This TLV contains the ROHC parameter MRRU. Both entities may include this TLV. The responder shall not send a value that is larger than the value sent by the requestor. If either entity sends a value = 0, or if both entities omit this TLV, then segmentation shall not apply. If only one entity includes this value, then that value is the negotiated value. Otherwise, the negotiated value is the lesser of the two values sent by the entities.

\text{Otherwise: } & \text{SFID for ROHC feedback.}
\end{align*} | DSA-REQ, DSA-RSP, DSC-REQ, DSC-RSP |

### 11.13.37 Packet Error Rate (PER)

This TLV indicates the target packet error rate (PER) for the service flow as defined below. This PER could either be the PER as seen by the application (post ARQ and/or HARQ processing) or as seen on the airlink (before the application of ARQ and/or HARQ). The particular use of this TLV is left open to implementations and vendor differentiations. Some usage scenarios, however could be: to determine whether to enable HARQ or not; to determine whether to enable ARQ or not; to choose a more aggressive or more robust burst profile etc. Support for setting the PER using this TLV is optional for both BS and MS.
11.13.38 PSC assignment

The PSC Assignment value specifies the Power_Saving_Class_ID of an existing PSC to which the CID of
the service flow shall be assigned. This TLV may be included only when the DSA or DSC protocol message
activates the service flow (i.e., includes an active QoS parameter set).

If the DSA or DSC protocol activates the service flow and the PSC Assignment TLV is present in the BS’s
DSA/DSC-REQ/RSP and specifies the Power_Saving_Class_ID of an existing PSC, then the CID of the
service flow is added immediately to the PSC at the time the service flow is activated. No explicit PSC re-
definition is needed.

<td>DSA-REQ/RSP, DSC-REQ/RSP</td>
</tr>
</tbody>
</table>

11.13.39 Group parameter Create/Change TLV

Group Parameter Create/Change provides a method to allow an MS or BS to create or change a number of
service flows, in a single DSx message exchange.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group parameter Create/Change</td>

</tr>
</tbody>
</table>
**Common Parameters** is a compound TLV value that encapsulates the common related service flow management encodings that are common to all service flows specified in this Group parameter Create/Change TLV. Only common related service flow encodings shall be included in this TLV. All the rules and settings that apply to the service flow management encodings when used in a DSA or DSC message apply to the contents encapsulated in this TLV. If included in the Group parameter Create/Change TLV, Common Parameters shall be the first attribute of the Group parameter Create/Change TLV. Common Parameters shall be included only once in a Group parameter Create/Change TLV.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length</th>

<td>SFID parameter list is a compound TLV value that encapsulates an SFID and associated noncommon service flow management encodings for that service flow, specified in this Group parameter Create/Change TLV. See the following Table for the format of the SFID parameter list. All the rules and settings that apply to the service flow management encodings when used in a DSA or DSC message apply to the contents encapsulated in this TLV. If included in the Group parameter Create/Change TLV, SFID parameter list shall be the last attribute. SFID parameter list may be included more than once in a DSx Group Create/Change TLV.</td>
</tr>
</tbody>
</table>
Packet Classification Rules and PHS Rules may be specified partly in the Common Parameters TLV (common part) and partly in the SFID parameter list TLV (specific part). In this case both parts of a rule are related to each other by means of their Index, Packet Classification Rule Index (11.13.18.3.3.14) and PHSI (11.13.18.3.5.1) respectively, that is to be included in both parts.

11.13.40 Aggregated HARQ channels TLV

The Aggregated HARQ channels TLV defines the HARQ channels which are used for aggregation in group 1 and group 2 of the H-FDD frame structure. The HARQ channels which are defined to be aggregated are encoded/decoded as a single burst.

<table>
<thead>
<tr>
<th>Name</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFID</td>
<td>4</td>
<td>See 11.13.1. If the SFID value is unassigned, the MS shall use an SFID value of ‘0’, though each iteration of ‘SFID’ in SFID parameter list represents a separate and individual service flow.</td>
</tr>
<tr>
<td>non-Common Parameters</td>
<td>variable</td>
<td>non-Common Parameters is a compound TLV value that encapsulates the non-common related service flow management encodings that are specific to individual service flows specified in this Group parameter Create/Change TLV. All the rules and settings that apply to the service flow management encodings when used in a DSA or DSC message apply to the contents encapsulated in this TLV.</td>
</tr>
</tbody>
</table>

ACID₁, ACID₂

The HARQ channel identifier corresponding to ACID₁ is used for the first part of the burst, while the HARQ channel identifier corresponding to ACID₂ is used for the second part of the burst.

When BS and MS negotiate the aggregated HARQ channels, the transmitter shall separate a single burst into the resources corresponding to the aggregated HARQ channels at the physical layer, and the receiver shall aggregate the resources corresponding to the HARQ channels at the physical layer as a single burst prior to decoding.

11.13.41 Priority indication

The value of this TLV, if present, indicates the associated flow is used for emergency purposes defined by local regulations. The exact conditions for when this TLV shall be included and the value that it shall convey are outside the scope of this standard. The behavior of the MS and BS when receiving this TLV is also outside the scope of this standard.

11.13.42 Regional Emergency Indication parameter

The value of this parameter, if present, indicates the associated flow is used for emergency purposes. The emergency indication parameter shall take precedence over any conflicting service flow QoS parameter.

<td>Requested cycle in which the paging message is transmitted within the paging group.</td>
<td>DREG-REQ</td>
</tr>
</tbody>
</table>
11.15 HO management encodings

11.15.1 Resource_Retain_Time

The Resource_Retain_Time is the duration for MS’s connection information that will be retained in serving BS. This value is measured in 100 ms. If this value is set to 0, the serving BS shall retain the MS’s connection information during Resource Retain Time negotiated at early registration stage. If this value is set to nonzero, it is the proposed Resource Retain Time by serving BS and the serving BS shall retain the MS’s connection information during that time after reception of MOB_HO-IND message (HO_IND_type=0b00).

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>0: The serving BS shall retain the MS’s connection information during Resource Retain Time negotiated at registration stage. 1–65535: Resource Retain Time (100 ms unit)</td>
<td>MOB_BSHO-REQ, MOB_BSHO-RSP</td>
</tr>
</tbody>
</table>

11.15.2 Alternate Target BS

The MS may include the Alternate_Target_BS TLV in a MOB_HO-IND message in which the HO_IND_type is set to 0b10 (HO reject, see 6.3.2.3.50) in order to indicate its preferred HO target. If the MS includes this TLV, the MS shall set bits 63–16 to the BS_ID of the proposed HO target, and shall set bits 15–0 to the preamble of the target BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>Bits 63–16: Target_BS_ID, Bits 15–0: Preamble Index/Subchannel Index</td>
<td>MOB_HO-IND</td>
</tr>
</tbody>
</table>

11.15.3 Additional Action Time

Instead of providing a single action time, the network may offer specific action times according to the Neighbor BS listed in MOB_BSHO-REQ or MOB_BSHO-RSP to increase the likelihood of successful fast ranging at a Target BS. In this case, the BS may include the “Additional Action Time” TLV in the MOB_BSHO-REQ or MOB_BSHO-RSP messages that the MS may use in addition to the Action Time indicated in the message. If this TLV is not present in the message, then the single Action Time value applies. An Action Time value of zero indicates no opportunity to allocate Fast Ranging IE at the respective target BS.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>variable: (N_{Recommended} \times 8) bits</td>
<td>Compound action time values for (N_{Recommended}) target base stations in the same sequence as presented in the message. Unit = frames.</td>
<td>MOB_BSHO-REQ, MOB_BSHO-RSP</td>
</tr>
</tbody>
</table>

The transmission order of Additional Action Time shall match the order of Neighbor BSID listed in the message.
11.16 Sleep mode management encodings

11.16.1 Co-located-coexistence-enabled

MS may include the Co-located-Coexistence-Enabled TLV in the MOB_SLP-REQ to indicate if coexistence behavior of the PSC is requested when the PSC is activated. If the BS supports the Co-located Coexistence Capability, the BS shall include this TLV in the MOB_SLP-RSP message transmitted in response to the MOB_SLP-REQ message containing this TLV.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Bit 0: Co-located coexistence mode 1</td>
<td>MOB_SLP-REQ,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1: Co-located coexistence mode 2</td>
<td>MOB_SLP-RSP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 2: Sleep mode follows the MAP relevance for co-located coexistence.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 3: Uplink band AMC for co-located coexistence</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 4: Indication for band AMC subchannel allocations</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b0: Subchannel allocation shall be to the lowermost frequencies.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>0b1: Subchannel allocation shall be to the uppermost frequencies.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 5–7: reserved</td>
<td></td>
</tr>
</tbody>
</table>

Bit 2 can be set to 1 only if bit 0 is set to 1 and bit 1 is set to 0.

Bit 4 shall be interpreted by the BS only if bit 3 is set to 1.

Only one instance of this Co-located-Coexistence-Enabled TLV should be added to the MOB_SLP-REQ and MOB_SLP-RSP messages.

11.16.2 Sleep mode functions enabled in H-FDD

<table>
<thead>
<tr>
<th>Type</th>
<th>Length (bits)</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>Bit 0: Sleep mode follows MAP relevance enabled</td>
<td>MOB_SLP-REQ,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Bit 1–7: Reserved</td>
<td>MOB_SLP-RSP</td>
</tr>
</tbody>
</table>

When bit 0 is set to 1, then the sleep mode follows MAP relevance (see 6.3.20.9). This bit is only relevant when MS and BS have successfully negotiated support for this feature during registration.

11.17 MOB_PAG-ADV management message encodings

The encoding described in this subclause is specific to the MOB_PAG-ADV message (6.3.2.3.51).
11.17.1 CDMA code and transmission opportunity assignment

The CDMA Code And Transmission Opportunity Assignment field indicates the assigned code and transmission opportunity for an MS that is paged to use over dedicated CDMA ranging region.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length (bits)</th>
<th>Value</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>150</td>
<td>variable; (8 + N_{assign} \times 16)</td>

</tr>
</tbody>
</table>

11.18 MOB_NBR-ADV management message encodings

The encodings described in this subclause are specific to the MOB_NBR-ADV message (6.3.2.3.42).
### 11.18.1 MOB_NBR-ADV message encodings

#### Table 609—MOB_NBR-ADV encodings

<table>
<thead>
<tr>
<th>Name</th>
<th>Type (1 byte)</th>
<th>Length (1 byte)</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCD_settings</td>
<td>1</td>
<td>variable</td>
<td>The DCD_settings is a compound TLV value that encapsulates TLVs from the neighbor BS’ DCD message that may be transmitted in the advertised BS downlink channel. This information is intended to enable fast synchronization of the MS with the advertised BS downlink. The DCD settings fields shall contain only neighbor’s DCD TLV values that are different from the serving BS corresponding values. Neighbor BS DCD TLVs that are already represented within the fixed fields of the MOB_NBR-ADV message (e.g., BS_EIRP, DCD configuration change count, neighbor BSID) shall be excluded. For values that are not included, the MS shall assume they are identical to the serving BSs corresponding values. If DCD/UCD Reference Indicator = 0 and the set of Triggers defined in the neighbor BS’s DCD is different from the set of Triggers in the Serving BS’s DCD, the serving BS includes the complete set of Trigger TLVs in the DCD settings compound TLV for the neighbor BS in the MOB_NBR-ADV. The MS uses this set of triggers defined in the DCD settings compound TLV when constructing the new DCD once the MS completes handover to the target. If no trigger TLVs are defined, the MS uses the trigger TLVs defined in the serving BS’s DCD. If DCD/UCD Reference Indicator = 1 and the set of Triggers defined for a neighbor BS’s DCD is different from the set of Triggers defined for the BS preceding the neighbor’s BS in the MOB_NBR-ADV, the serving BS includes the complete set of Trigger TLVs in the DCD settings compound TLV for the neighbor BS in the MOB_NBR-ADV. When the MS constructs the DCD once the MS completes handover to the target. It uses one of the following sets of triggers: 1. MS uses the set of triggers defined in the DCD settings TLV for the neighbor BS in the MOB_NBR-ADV. 2. If no triggers are defined in the DCD settings TLV for the neighbor BS in the MOB_NBR-ADV, the MS uses the triggers defined in the DCD settings TLV for the previous neighbor BS in the MOB_NBR-ADV (only if DCD/UCD Reference Indicator = 1). 3. If no triggers are defined in the DCD settings TLV for the neighbor BS or the previous neighbor BS (if DCD/UCD Reference Indicator = 1) in the MOB_NBR-ADV, the MS uses the set of triggers defined in the DCD settings TLV for the serving BS.</td>
</tr>
</tbody>
</table>
The neighbor BS trigger TLV (type 4) in Table 609 is encoded using the description in Table 610.

<table>
<thead>
<tr>
<th>UCD_settings</th>
<th>2</th>
<th>variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>The UCD_settings is a compound TLV that encapsulates TLVs from the neighbor BS’ UCD message that may be transmitted in the advertised BS downlink channel. This information is intended to enable fast synchronization of the MS with the advertised BS uplink. The UCD settings fields shall contain only neighbor’s UCD TLV values that are different from the serving BS’s corresponding values or from the UCD_settings of the previous neighbor BS, whichever is referenced by the DCD/UCD Reference Indicator in the PHY Profile ID. Neighbor BS UCD TLVs that are already represented within the fixed fields of the MOB_NBR-ADV message (e.g., UCD configuration change count) shall be excluded. For values that are not included, the MS shall assume they are identical to the serving BS’s corresponding values.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Neighbor BS trigger</th>
<th>4</th>
<th>variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Neighbor BS trigger is a compound TLV that defines a trigger (Table 610). The resulting set of triggers that the MS shall apply to this neighbor BS is specified in 6.3.2.3.42, Table 145. Neighbor BS trigger TLVs are included in MOB_NBR-ADV message, only if the resulting set of triggers is different from trigger set that is defined in the serving BS’s DCD message or from the Neighbor BS trigger set for the preceding neighbor BS, whichever is referenced by the Trigger Reference Indicator in the PHY Profile ID.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 610—Neighbor BS Trigger TLV description

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (1 byte)</th>

</tr>
<tr>
<td>Trigger averaging duration</td>
<td>4.3</td>
<td>1</td>
<td>Trigger averaging duration is the time measured in number of frames over which the metric measurements are averaged.</td>
</tr>
</tbody>
</table>
If Neighbor BS Trigger TLVs are included in the MOB_NBR-ADV message, the MS may ignore Neighbor BS Trigger TLVs having a metric that the MS and BS have not agreed to support during SBC-REQ/RSP message exchange.

When the mean value of the MS's measurements over the averaging interval of a trigger defined by a Neighbor BS Trigger TLV meets the trigger condition as specified by the type, function, and value of the trigger, the MS shall invoke the trigger's specified action. Whenever the trigger condition of a trigger is met, the MS shall invoke the action of the trigger. If more than one trigger conditions are met simultaneously the MS shall invoke the action of at least one of the triggers.

The MS may transmit MOB_MSHO-REQ and MOB_SCN-REQ messages autonomously, i.e., in addition to messages prompted by trigger conditions.

</table>

11.20.2 Sleep mode reactivation information

When the start of the scanning procedure deactivates the Power Saving Class of Type I associated with the MS’s Basic CID, the MS may request the BS to automatically reactivate the PSC after completion of the scanning procedure, and the BS shall specify the frame offset from the end of the scanning procedure to the start of the reactivated sleep mode operation. The BS shall not include Sleep Mode Reactivation Information TLV in the MOB_SCN-RSP if the MS has not requested it. Also, if the BS wants to deny the MS request for
automatic PSC reactivation, the BS shall not include the Sleep Mode Reactivation Information TLV in the MOB_SCN-RSP.

</tbody>
</table>

Table 614—Contents of the Absolute Position (Long Format) TLV

<table>
<thead>
<tr>
<th>Field</th>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
</table>
| Longitude | 40 bits | Bits 0–5: longitude resolution  
1-34 - number of valid bits in fixed-point value of longitude value  
35 - LBS not supported  
Others - Reserved  
Bits 6–14: longitude integer  
Bits 15–39: longitude fraction |
| Latitude  | 40 bits | Bits 0–5: latitude resolution  
1-34 - number of valid bits in fixed-point value of latitude value  
35 - LBS not supported  
Others - Reserved  
Bits 6–14: latitude integer  
Bits 15–39: latitude fraction |
| Altitude  | 40 bits | Bits 0–3: altitude type  
1-meters  
2-floors  
Others - Reserved  
Bits 4–9: altitude resolution  
1-30 - number of valid bits in fixed-point value of altitude value  
31 - LBS not supported  
Others - Reserved  
Bits 10–31: altitude integer  
Bits 32–39: altitude fraction |

The latitude, longitude and altitude within the Absolute Position (Long Format) TLV indicate the BS location in latitude, longitude, and altitude that are based on the LCI (Location Configuration Information) format as defined in IETF RFC 3825. Latitude and longitude are each represented as a 34 bit fixed-point...
2’s-complement number, consisting of 9 bits of integer and 25 bits of fraction. Altitude is represented as a 30 bit fixed-point 2’s-complement number with 22 bits of integer and 8 bits of fraction. Latitude and longitude should be normalized to within ±90 degrees and ±180 degrees, respectively. Each field also includes resolution bits that define the number of valid bits in the fixed-point value. Here are the definition of 2’s-complement number.

— Positive numbers
  1) Latitude - North
  2) Longitude - East
  3) Altitude - above ground
— Negative numbers
  1) Latitude - South
  2) Longitude - West
  3) Altitude - below ground

11.21.2 Absolute Position TLV (Short Format)

This TLV is used to provide the absolute position of a BS.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (bytes)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absolute Position (Short Format)</td>
<td>2</td>
<td>6 or 8</td>
<td>See Table 615</td>
</tr>
</tbody>
</table>

**Table 615—Contents of the Absolute Position (Short Format) TLV**

<table>
<thead>
<tr>
<th>Field</th>
<th>Size</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Longitude</td>
<td>24 bits</td>
<td>Longitude expressed in (2^{-15}) parts of a degree</td>
</tr>
<tr>
<td>Latitude</td>
<td>24 bits</td>
<td>Latitude expressed in (2^{-16}) parts of a degree</td>
</tr>
<tr>
<td>Altitude</td>
<td>16 bits</td>
<td>Bits 0–15: altitude in meters above sea level</td>
</tr>
</tbody>
</table>

In the Absolute Position (Short Format) TLV, longitude and latitude are expressed as \(2^{-15}\) and \(2^{-16}\) parts of a degree respectively using 2’s complement notation to express negative (West or South) values. The altitude field is optionally included. The MS can determine the presence of the Altitude field by using the length field. Altitude is expressed in meters above sea level using 2’s complement notation to express negative (below sea level) values.

11.21.3 Relative Position TLV

This TLV shall be used to provide the absolute position of a BS relative to a reference point.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (bytes)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relative Position</td>
<td>3</td>
<td>4 or 6</td>
<td>See Table 616</td>
</tr>
</tbody>
</table>
The Relative Position TLV is used to indicate the positions of additional BSs as offsets in meters from the Latitude, Longitude and Altitude values of the first Absolute Position TLV in the message. The altitude field is optionally included. The MS can determine the presence of the Altitude field by using the length field. Negative values are expressed using 2’s complement notation to denote positions South, West and below the reference position. The scaling of these numbers allows the position of a BS within 32 km from the first BS to be described.

11.21.4 GPS Time TLV

This TLV shall be used to provide the GPS time.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (bytes)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPS Time</td>
<td>4</td>
<td>5</td>
<td>See Table 617</td>
</tr>
</tbody>
</table>

Table 617—Contents of the GPS Time TLV

<table>
<thead>
<tr>
<th>Field</th>
<th>Size (bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPS time in units of frame duration</td>
<td>22</td>
<td>GPS time, expressed in units of frame duration ( T_f ), modulo ( 2^{22} )</td>
</tr>
<tr>
<td>GPS frame transmission time offset</td>
<td>10</td>
<td>A signed integer expressing the difference between the OFDMA frame transmission time and the nearest integer multiple of ( T_f ), expressed in units of 2 nanoseconds (ns). Negative values express late transmission. This integer is encoded in two’s complement notation. The value 0x200 signals that the offset in absolute value is greater than ((2^9 - 1) \times 2 ) ns.</td>
</tr>
<tr>
<td>GPS time accuracy</td>
<td>5</td>
<td>This field encodes an upper bound of the accuracy ( \alpha = 2^p ) picoseconds, by providing the binary representation of ( p ). For example, 0b011110 encodes an accuracy less than or equal to ( \alpha = 2^{14} ) ps =16.384 ns. Conversely, if the accuracy is 8 ns, a minimal upper bound is encoded by the bit representation of ( p = \lceil \log_2(8000) \rceil = 13 ), i.e., 0b01101</td>
</tr>
<tr>
<td>Reserved</td>
<td>3</td>
<td></td>
</tr>
</tbody>
</table>

In the following equations:

- \( T_f \) is the frame duration;
- \( f_{TX} \) is the time in units of seconds relative to GPS time (i.e., where time 0 denotes January 6th, 1980, 12:00 AM GMT) of the start time of the frame that carries this TLV,
— $t_{MS}$ is the time in units of seconds at the MS according to its internal clock when it receives the LBS-ADV message;
— $n_f$ is the frame number in which the LBS-ADV message is transmitted;
— $m$ is the modulus used, i.e., $m = 2^{22} \times T_f$;
— $n_0$ is the value transmitted in the “GPS time in units of frame duration” field;
— $k$ is the value transmitted in the “GPS frame transmission offset” field;
— $\alpha$ is the value transmitted in the “GPS time accuracy” field.

**GPS time in units of frame duration**

This parameter shall be set to a value $n_0$, where $n_0 = \left\lfloor t_{TX} / T_f + n_f + 0.5 \right\rfloor \mod (m / T_f)$.

**GPS frame transmission offset**

This parameter shall be set to a value $k$, where $|2k \ ns + t_{TX} - \left\lfloor t_{TX} / T_f + 0.5 \right\rfloor T_f| < \alpha$. If $|k| > 2^{32} - 1$, the BS shall set this field to 0x200.

**GPS time accuracy**

This parameter shall be set to a value $\alpha$, where $n_0 = \left\lfloor t_{TX} / T_f + n_f + 0.5 \right\rfloor \mod (m / T_f)$.

The GPS Time TLV informs the receiving MS of the precise time at which the BS transmits frame number 0, which the MS may use to calibrate its own internal clock in reference to the GPS time standard. If $|t_{TX} - t_{MS}| < m / 2$, the MS computes $t_{TX}$ as follows: $t_{TX} = (n_0 + n_f)T_f + 2k \ ns + \varepsilon + Nm$, where

$$N = \left\lfloor \frac{t_{MS} - (n_0 + n_f)T_f}{m} + 0.5 \right\rfloor,$$

$\varepsilon < |\varepsilon| < \alpha$.

The GPS Time TLV is used if the BS’s frame time is synchronized with the GPS clock. This may be particularly valuable for determining GPS satellite signal search windows in mobiles equipped to detect GPS satellites. GPS frame transmission time offset allows the MS to use DL Frame arrival times as timing signals aligned with GPS time. GPS Time Accuracy aids the MS in estimating how much error with respect to GPS time the BS may have when using this calibration.

**11.21.5 Frequency Accuracy TLV**

This TLV shall be used to provide the frequency accuracy information.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Length (bytes)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frequency info</td>
<td>5</td>
<td>1</td>
<td>BS transmit frequency accuracy in ppm. For values in range 0x00-0xFE, frequency max error is $\pm [(value+1) \times 0.01 \text{ ppm}]$. For example, if value = 0x20, max TX frequency error is $\pm 0.33 \text{ ppm}$. The BS shall send the value 0xFF to indicate that it does not specify transmit frequency accuracy for location-based service.</td>
</tr>
</tbody>
</table>
12. System profiles

This clause defines system profiles listing sets of features to be used in typical implementation cases. Each profile is assigned an identifier for use in documents such as PICS proforma statements. These profiles do not alter the mandatory or optional nature of features specified elsewhere in this standard. Compliance to a profile depends on compliance with the underlying radio interface specification in the appropriate variant. In addition, features specified as “required” in a profile are required for compliance to that profile. Likewise, features specified as “conditionally required” in a profile are required for compliance to that profile under the specified conditions.

12.1 WirelessMAN-SC Release 1.0

Table 618 defines system profiles for systems operating with the WirelessMAN-SC air interface.

</table>

12.1.1 WirelessMAN-SC MAC system profiles

This subclause defines MAC profiles for systems operating with the WirelessMAN-SC air interface.

12.1.1.1 Basic ATM MAC system profile

Profile identifier: profM1.

Mandatory features:

— Support of PVCs.
— Support of VC-switched connections.
— Support of VP-switched connections.
— ATM PHS is mandatory as a capability, but may be turned on or off on a per-connection basis.
— IPv4 on the secondary management connection.
— Packing of multiple ATM cells into a single MAC PDU is mandatory as a capability, but may be turned on or off on a per-connection basis.
— SDU fragmentation on the primary management and secondary management connections.
Conditionally mandatory features:

- If nrtPS or BE service is supported, then the SS responding to broadcast polling is mandatory.
- If multicast polling groups are supported, multicast polling shall be supported.

### 12.1.1.2 Basic Packet MAC system profile

Profile identifier: profM2.

**Mandatory features:**

- Support of provisioned connections.
- IPv4 support on transport connection.
- Classification of packets in the SS based on the incoming physical port.
- Reception of multiple SDUs packed into a single MAC PDU is mandatory as a capability, but may be turned on or off on a per-connection basis.
- Fragmentation of SDUs is mandatory as a capability, but may be turned on or off on a per-connection basis.

Conditionally mandatory features:

- If nrtPS or BE service is supported, then the SS responding to broadcast polling is mandatory.
- If multicast polling groups are supported, multicast polling shall be supported.

### 12.1.1.3 Conventions for MAC management messages for profiles profM1 and profM2

The following rules shall be followed when reporting parameters in MAC Management messages:

- Service Class Names should not be used.
- No TLVs besides HMAC Tuples shall be reported back in DSA-RSP and DSC-RSP messages.
- No TLVs besides HMAC Tuples shall be reported back in DSA-ACK messages.
- DSC-REQ messages shall not contain Request/Transmission Policy, Fixed vs. Variable Length SDU Indicator, SDU Size, ATM Switching, or Convergence Sublayer Specification TLVs.

### 12.1.1.4 MAC management message parameter transmission order

The following subclauses define the order in which systems meeting profiles profM1 and profM2 shall transmit the TLV encoded parameters for mandatory features in the respective messages. Systems implementing either profile shall only include the parameters listed under the respective message in its transmission of these messages plus any parameters necessary for optional features. Parameters for optional features shall occur after those listed for support of mandatory features. Parameters with defined default values should be omitted if the desired value coincides with the default one. PHY specific messages are described in 12.1.2.

#### 12.1.1.4.1 DCD

The parameters of the DCD message are PHY profile specific.

#### 12.1.1.4.2 DL-MAP

This message contains no TLV encoded information.
12.1.1.4.3 UCD

The parameters of the UCD message are PHY profile specific.

12.1.1.4.4 UL-MAP

This message contains no TLV encoded information.

12.1.1.4.5 RNG-REQ

- Requested Downlink Burst Profile
- SS MAC Address
- Ranging Anomalies

12.1.1.4.6 RNG-RSP

If ranging status equals “success” or “continue”

- Ranging Status
- Timing Adjust (default to 0)
- Power Adjust (default to 0)
- Downlink Operational Burst Profile (only if changed)
- SS MAC Address (only on CID 0x0000)
- Basic CID (only on CID 0x0000)
- Primary Management CID (only on CID 0x0000)
- Uplink Channel Override (only if allowed by PHY profile)

If ranging status equals “abort”

- Ranging Status
- SS MAC Address (only on CID 0x0000)
- Downlink Frequency Override (if needed)

12.1.1.4.7 REG-REQ

- Vendor ID Encoding (optional)
- CID Support
- DSx Flow Control (default = no limit)
- MCA Flow Control (default = no limit)
- IP version (default = IPv4)
- MAC CRC support (default = support)
- Multicast Polling Group CID support (default = 4)
- Convergence Sublayer Support (1 instance for each CS supported)
- Maximum number of classifiers (default = 0, no limit)
- PHS support (default = 0, no PHS support)
- HMAC Tuple

12.1.1.4.8 REG-RSP

- Secondary Management CID
- Uplink CID Support
- Vendor ID Encoding (if present in REG-REQ)
- PKM Flow Control (if present in REG-REQ or changed from default)
- DSx Flow Control (if present in REG-REQ or changed from default)
— MCA Flow Control (if present in REG-REQ or changed from default)
— IP version (if present in REG-REQ or changed from default)
— MAC CRC support (if present in REG-REQ or changed from default)
— Multicast Polling Group CID support (if present in REG-REQ or changed from default)
— Vendor-specific information (Compound, only allowed if Vendor ID present in REG-REQ, and extensions provided)
— Vendor ID
— Vendor-specific extensions
— HMAC Tuple

12.1.1.4.9 PKM-REQ: Auth Info

— CA-Certificate

12.1.1.4.10 PKM-REQ: Auth Request

— SS-Certificate
— Security Capabilities
— Version (default = 1)
— Cryptographic-Suite-List (default is that both no encryption and 56-bit DES are supported, no data authentication, and 3-DES EDE with 128-bit key)
— SAID

12.1.1.4.11 PKM-REQ: Key Request

— Key Sequence Number
— SAID
— HMAC-Digest

12.1.1.4.12 PKM-RSP: SA Add

— Key-Sequence-Number
— SA-Descriptor(s)
— SAID
— SA-Type
— Cryptographic Suite
— HMAC-Digest

12.1.1.4.13 PKM-RSP: Auth Reply

— AUTH-Key
— Key-Lifetime
— Key-Sequence-Number
— SA-Descriptor(s)
— SAID
— SA-Type
— Cryptographic Suite

12.1.1.4.14 PKM-RSP: Auth Reject

— Error Code
— Display String (optional)
12.1.1.4.15 PKM-RSP: Key Reply

- Key Sequence Number
- SAID
- TEK-Parameters (Older)
- TEK
- Key Lifetime
- Key Sequence Number
- CBC-IV
- TEK-Parameters (Newer)
- TEK
- Key Lifetime
- Key Sequence Number
- CBC-IV
- HMAC-Digest

12.1.1.4.16 PKM-RSP: Key Reject

- Key Sequence Number
- SAID
- Error Code
- Display String (optional)
- HMAC-Digest

12.1.1.4.17 PKM-RSP: Auth Invalid

- Error Code
- Display String (optional)

12.1.1.4.18 PKM-RSP: TEK Invalid

- Key Sequence Number
- SAID
- Error Code
- Display String (optional)
- HMAC-Digest

12.1.1.4.19 DSA-REQ: BS Initiated Service Addition

- Uplink Service Parameters
- Service Flow ID
- Transport CID
- Target SAID
- QoS Parameter Set Type
- Service Flow Scheduling Type
- Request/Grant Transmission Policy
- Convergence Sublayer Specification
- Fixed vs Variable Length SDU Indicator (default = variable)
- SDU Size (required if fixed, forbidden if variable SDU)
- Maximum Sustained Traffic Rate
- Minimum Reserved Traffic Rate (default = 0 for BE, Max Sust Rate for UGS, required for rtPS and nrtPS)
- Maximum Traffic Burst (required for rtPS and nrtPS, excluded otherwise)
- Traffic Priority (optional, BE only)
— Tolerated Jitter (optional)
— Maximum Latency (optional)
— Convergence Sublayer Specific Parameters (see 12.1.1.5 and 12.1.1.6)
— Vendor-Specific QoS Parameters
— Downlink Service Parameters
— Service Flow ID
— Transport CID
— Target SAID
— QoS Parameter Set Type
— Service Flow Scheduling Type
— Request/Grant Transmission Policy
— Convergence Sublayer Specification
— Fixed vs. Variable Length SDU Indicator (default = variable)
— SDU Size (required if fixed, forbidden if variable SDU)
— Convergence Sublayer Specific Parameters (see 12.1.1.5 and 12.1.1.6)
— Vendor-specific QoS Parameters
— HMAC Tuple

12.1.1.4.20 DSA-RSP: BS-initiated service addition

— Uplink Service Parameters
— Downlink Service Parameter(s)
— HMAC Tuple

12.1.1.4.21 DSA-ACK

— HMAC Tuple

12.1.1.4.22 DSC-REQ: BS-initiated service change

— Uplink Service Parameters
— Service Flow ID
— Transport CID
— QoS Parameter Set Type
— Maximum Sustained Traffic Rate
— Minimum Reserved Traffic Rate (default = 0 for BE, Max Sust Rate for UGS, required for rtPS and nrtPS)
— Maximum Traffic Burst (required for rtPS and nrtPS, excluded otherwise)
— Traffic Priority (optional, BE only)
— Tolerated Jitter (optional)
— Maximum Latency (optional)
— Convergence Sublayer Specific Parameters (see 12.1.1.5 and 12.1.1.6)
— Vendor-specific QoS Parameters
— Downlink Service Parameters
— Service Flow ID
— Transport CID
— QoS Parameter Set Type
— Convergence Sublayer Specific Parameters (see 12.1.1.5 and 12.1.1.6)
— Vendor-specific QoS Parameters
— HMAC Tuple
12.1.1.4.23 DSC-RSP: BS-initiated service change

- WirelessMAN-SC PHY SS Demod Support
- WirelessMAN-SC PHY SS Modulator Support
- WirelessMAN-SC PHY SS Downlink FEC Types
- WirelessMAN-SC PHY SS Uplink FEC Types
12.1.1.4.34 CLK-CMP

The message contains no TLV encoded information.

12.1.1.4.35 DREG-CMD

— HMAC Tuple

12.1.1.4.36 DSX-RVD

The message contains no TLV encoded information.

12.1.1.4.37 TFTP-CPLT

— HMAC Tuple

12.1.1.4.38 TFTP-RSP

The message contains no TLV encoded information.

12.1.1.5 Message parameters specific to profM1

The following subclauses define the order in which systems meeting profile profM1 shall transmit the TLV encoded parameters specific to the ATM CS. Parameters with defined default values should be omitted if the desired value coincides with the default one.

12.1.1.5.1 ATM CS Parameters for DSA-REQ: BS Initiated

— ATM Switching
— ATM Classifier Rule(s) (default = don’t classify)
— ATM Classifier ID
— VPI Classifier
— VCI Classifier(s) (shall follow associated VPI, default = don’t classify on VCI)

12.1.1.5.2 ATM CS Parameters for DSA-RSP: BS Initiated

— None

12.1.1.5.3 ATM CS Parameters for DSC-REQ: BS Initiated

— ATM Classifier Change Action
— ATM Classifier Rule(s) (default = don’t classify)
— ATM Classifier ID
— VPI Classifier
— VCI Classifier(s) (shall follow associated VPI, default = don’t classify on VCI)

12.1.1.5.4 ATM CS Parameters for DSC-RSP: BS Initiated

— None
12.1.1.6 Message parameters specific to profM2

12.1.1.6.1 Packet CS parameters for DSA-REQ: BS-initiated

- Packet Classification Rule(s) (UL service flows only, default is no classification)
- Classifier Rule Index
- Classifier Rule Priority (default to 0)
- IP Type of Service/DSCP (only for IP CSs, default = don’t classify on this)
- Protocol (only for IP CSs, default = don’t classify on this)
- IP Masked Source Address (only for IP CSs, default = don’t classify on this)
- IP Destination Address (only for IP CSs, default = don’t classify on this)
- Protocol Source Port Range (only for IP CSs, default = don’t classify on this)
- Protocol Destination Port Range (only for IP CSs, default = don’t classify on this)
- IPv6 Flow Label field (only for IP CSs, default = don’t classify on this)
- Ethernet Destination MAC Address (only for Ethernet CSs, default = don’t classify on this)
- Ethernet Source MAC Address (only for Ethernet CSs, default = don’t classify on this)
- Ethertype/IEEE 802.2 SAP (only for Ethernet CSs, default = don’t classify on this)
- IEEE 802.1D User Priority (only for Ethernet CSs on which VLAN headers carry the priority bits, default = don’t classify on this)
- IEEE 802.1Q VLAN_ID (only for Ethernet CSs, default = don’t classify on this)
- Associated PHSI (default is no PHS for this classifier match)
- Vendor-specific Classifier Parameters
  - PHS Rule(s)
  - PHSI
  - PHSS
  - PHSF
  - PHSM (default is suppress all bytes of the suppression field)
  - PHSV (default is verify)

12.1.1.6.2 Packet CS parameters for DSA-RSP: BS-initiated

- Packet Classification Rule(s) (UL service flows only, default is no classification)
- PHS Rule(s)

12.1.1.6.3 Packet CS Parameters for DSC-REQ: BS Initiated

- Classifier Dynamic Service Change Action(s)
- Packet Classification Rule(s) (UL service flows only, 1 per Action)
- Classifier Rule Index
- Classifier Rule Priority (default to 0)
- IP Type of Service/DSCP (only for IP CSs, default = don’t classify on this)
- Protocol (only for IP CSs, default = don’t classify on this)
- IP Masked Source Address (only for IP CSs, default = don’t classify on this)
- IP Destination Address (only for IP CSs, default = don’t classify on this)
- Protocol Source Port Range (only for IP CSs, default = don’t classify on this)
- Protocol Destination Port Range (only for IP CSs, default = don’t classify on this)
- IPv6 Flow Label field (only for IP CSs, default = don’t classify on this)
- Ethernet Destination MAC Address (only for Ethernet CSs, default = don’t classify on this)
- Ethernet Source MAC Address (only for Ethernet CSs, default = don’t classify on this)
- Ethertype/IEEE 802.2 SAP (only for Ethernet CSs, default = don’t classify on this)
- IEEE 802.1D User Priority (only for Ethernet CSs on which VLAN headers carry the priority bits, default = don’t classify on this)
- IEEE 802.1Q VLAN_ID (only for Ethernet CSs, default = don’t classify on this)
— Associated PHSI (default is no PHS for this classifier match)
— Vendor-specific Classifier Parameters
— PHS Dynamic Service Change Action
— PHS Rule(s) (1 per Action)
— PHSI
— PHSS
— PHSF
— PHSM (default is suppress all bytes of the suppression field)
— PHSV (default is verify)
— Vendor-specific PHS Parameters

12.1.1.6.4 Packet CS Parameters for DSC-RSP: BS Initiated

— Uplink Service Parameters
— Downlink Service Parameter(s)

12.1.2 WirelessMAN-SC PHY Profiles

This subclause defines PHY profiles for systems operating with the WirelessMAN-SC PHY.

12.1.2.1 WirelessMAN-SC 25 MHz Channel PHY Profile

Profile identifier: profP1.

Mandatory features:

— Frame duration of 1 ms
— QPSK and QAM-16 in the DL
— QPSK in the UL
— Roll-off Factor = 0.25
— RS outer codes with $t \in \{0, 4, 8, 10, 12\}$.
— Fixed and shortened last code word operation.
— RS block lengths of 6–255.
— 20 MBd symbol rate
— 5000 PS per frame

SSs implementing profP1 shall meet the minimum SS performance requirements listed in Table 619.

12.1.2.1.1 FDD Specific WirelessMAN-SC 25 MHz Channel PHY Profile features

Profile identifier: profP1f.

Mandatory features:

— FDD operation
— BS shall respect half-duplex nature of half-duplex SSs

12.1.2.1.2 TDD Specific WirelessMAN-SC 25 MHz Channel PHY Profile features

Profile identifier: profP1t.

Mandatory features:

— TDD operation

12.1.2.2 WirelessMAN-SC 28 MHz Channel PHY Profile

Profile identifier: profP2.

Mandatory features:

— Frame duration of 1 ms
— QPSK and QAM-16 in the DL
— QPSK in the UL
— Roll-off Factor = 0.25
— RS outer codes with \( t \in \{0, 4, 8, 10, 12\} \)
— Fixed and shortened last code word operation
— RS block lengths of 6–255
— 22.4 MBd symbol rate
— 5600 PS per frame

SSs implementing profP2 shall meet the minimum SS performance requirements as listed in Table 622.

12.1.2.2.1 FDD Specific WirelessMAN-SC 28 MHz Channel PHY Profile features

Profile identifier: profP2f.

Mandatory features:

- FDD operation
- BS shall respect half-duplex nature of half-duplex SSs

12.1.2.2.2 TDD Specific WirelessMAN-SC 28 MHz Channel PHY Profile features

Profile identifier: profP2t.

Mandatory features:

- TDD operation

12.1.2.3 Conventions for MAC Management messages for profiles profP1 and profP2

The following rules shall be followed when reporting parameters in MAC Management messages for systems operating PHY profiles profP1 or profP2:

- Symbol rate, frequency, and roll-off factor shall not be reported in UCD messages.
- BCC code type shall not be reported in UCD messages.
- Frame duration shall not be reported in DCD messages.
- BCC code type shall not be reported in DCD messages.
- UL channel override shall not be reported in RNG-RSP messages.

12.1.2.4 UCD and DCD parameter transmission order for profP1 and profP2

The following subclauses define the order in which systems meeting profiles profP1 and profP2 shall transmit the TLV encoded parameters in the respective messages. Systems implementing either profile shall only include the parameters listed under the respective message in its transmission of these messages. Parameters with defined default values should be omitted if the desired value coincides with the default one.

12.1.2.4.1 DCD

- BS Transmit Power
- PHY Type
- Power Adj Rule
- Downlink Burst Profile(s)
- Modulation Type
- FEC Code Type (default to RS only if omitted)
- RS Information Bytes
- RS parity bytes
- Last Codeword Length (default to shortened if omitted)
- Exit Threshold
- Entry Threshold
- Preamble Present (default to “not present” if omitted)

12.1.2.4.2 UCD

- SS Transition Gap (default to 24 symbols if omitted)
- Power Adjustment Rule
— Contention-based Reservation Timeout
— Uplink Burst Profile(s)
— Modulation Type
— Preamble Length
— FEC Code Type (default to RS only)
— RS Information Bytes
— RS Parity Bytes
— Randomizer Seed
— Last Codeword Length (default to shortened)

12.1.2.5 Initial Ranging IE usage for profP1 and profP2

BSs implementing profP1 or profP2 shall include exactly one Initial Ranging IE in the UL-MAP for each intended opportunity for an SS to perform initial ranging.

12.2 Reserved

12.3 Fixed WirelessMan-OFDM

This subclause defines system profiles for systems operating with the WirelessMAN-OFDM air interface and with the WirelessHUMAN interface where it uses the OFDM PHY.

A system profile consists of five components: a MAC profile, a PHY profile, a RF profile, a duplexing selection, and a power class. The defined PHY and MAC profiles are listed in Table 625.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Description</th>

<td>WirelessHUMAN(-OFDM) 10 MHz channel basic PHY profile</td>
</tr>
</tbody>
</table>

The Tx power class profiles, as shown in Table 626, are based on the maximum mean Tx power $P_{Tx,max}$ using all nonguard subcarriers, for which the transmitter requirements as defined in 8.3.10 are met.

The duplexing shall be selected as follows: A system shall implement TDD and/or FDD. A FDD SS system may be implemented either as half-duplex or as full-duplex. A FDD BS system shall respect the half-duplex nature of half-duplex SSs.

Using these conventions, a sample system profile is shown in Table 627. This sample system profile may also be represented by a concatenation of the profile components:

profM3_PMP.profP3_10.profR10_1.TDD.profC3_17.
This subclause defines MAC profiles for systems operating with the WirelessMAN-OFDM air interface and with the WirelessHUMAN interface where it uses the OFDM PHY.

### 12.3.1 WirelessMAN-OFDM and WirelessHUMAN(-OFDM) MAC profiles

This subclause defines MAC profiles for systems operating with the WirelessMAN-OFDM air interface and with the WirelessHUMAN interface where it uses the OFDM PHY.

#### 12.3.1.1 ProfM3_PMP: Basic Packet PMP MAC System profile

This profile specifies a set of capability requirements when a system is operating in the mandatory PMP mode. Table 628 lists the optional MAC features and designates whether they shall or may be implemented to comply with this profile.

- Support of IPv4 capabilities at the packet CS means capability of classification and IPv4 datagrams encapsulation into MAC SDUs as specified in 5.2.5. It is relevant to both DL and UL.
- Support of IEEE 802.3/Ethernet capabilities at the packet CS means capability of classification and IEEE 802.3/Ethernet frames encapsulation into MAC SDUs as specified in 5.2.4. It is relevant to both DL and UL.
- Support of ARQ is defined as the minimum capability to support eight simultaneous ARQ connections.
- Support of CRC means ability to add CRC at Tx and ability to check CRC at Rx in the case when CRC presence is signaled by CI.

12.3.1.1.1 Conventions for MAC Management messages

The following rules shall be followed when reporting parameters in MAC Management messages:

- Service Class Names should not be used.
- DSC-REQ messages shall not contain Request/Transmission Policy, Fixed vs. Variable Length SDU Indicator, SDU Size, ATM Switching, or Convergence Sublayer Specification TLVs.
12.3.1.1.2 MAC Management Message Parameter Transmission Order

TLVs within MAC Management messages shall be ordered as follows:

— Parameters for optional features shall occur after those listed for support of mandatory features.
— Features that are defined as optional, but are mandated by the implemented Profile, if any, shall be ordered as optional.
— Both mandatory and optional TLVs shall subsequently be sequenced in order of increasing Type value except for the HMAC TLV, which shall be the final attribute in the TLV attribute list of the messages.
— Parameters with defined default values should be omitted if the desired value coincides with the default one.

12.3.1.2 Reserved

12.3.2 WirelessMAN-OFDM and WirelessHUMAN(-OFDM) PHY profiles

This subclause defines PHY profiles for systems operating with the WirelessMAN-OFDM and WirelessHUMAN(-OFDM) air interface.

The following set of parameters are common to all defined PHY profiles and shall be complied with in order to comply with each individual profile.

Table 629 lists the optional PHY features and designates whether they shall or may be implemented.

12.3.3 WirelessMAN-OFDM RF profiles

For licensed bands, no explicit RF profiles are defined. A compliant system shall adhere to the requirements of 8.3.10.4 for the specified supported bands.

12.3.3.1 RF profiles for 10 MHz channelization

12.3.3.1.1 ProfR10_1

Mandatory features:

— RF channels: $5000 + n \cdot 5$ MHz, $\forall n \in \{55, 57, 59, 61, 63, 65, 67\}$
— Spectral mask: See 8.5.2.

12.3.3.1.2 profR10_2

Mandatory features:

— RF channels: $5000 + n \cdot 5$ MHz, $\forall n \in \{148, 150, 152, 154, 156, 158, 160, 162, 164, 166\}$
— Spectral mask: See 8.5.2.

12.3.3.1.3 profR10_3

Mandatory features:

— RF channels: $5000 + n \cdot 5$ MHz, $\forall n \in \{147, 149, 151, 153, 155, 157, 159, 161, 163, 165, 167\}$
— Spectral mask: See 8.5.2.
12.4 Fixed WirelessMAN-OFDMA

This subclause defines system profiles for systems operating with the WirelessMAN-OFDMA and WirelessHUMAN-OFDMA air interfaces.

Any feature not mandatory or conditionally mandatory for a profile is optional for the profile except where otherwise forbidden by the standard. Optional features shall be implemented as specified in the standard.

<table>

12.4.1 WirelessMAN-OFDMA Power class profiles

A power class profile contains the class(es) of BS and SS transmitters used in a system. A power class profile may contain transmitters from more than one class, with the profile indicating the highest power level class permitted.

The power classes for BS and SS transmitters in a system are listed in Table 638.

<table>
<thead>
<tr>
<th>Class identifier</th>
<th>Tx power (dBm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class 1</td>
<td>17 \leq P_{Tx,max} &lt; 20</td>
</tr>
<tr>
<td>Class 2</td>
<td>20 \leq P_{Tx,max} &lt; 23</td>
</tr>
<tr>
<td>Class 3</td>
<td>23 \leq P_{Tx,max} &lt; 30</td>
</tr>
<tr>
<td>Class 4</td>
<td>30 \leq P_{Tx,max}</td>
</tr>
</tbody>
</table>

The power ratings, \( P_{Tx,max} \), associated with these classes are the maximum average output power ratings at which the appropriate transmitter requirements in 8.4.13 are met.
12.4.2 WirelessMAN-OFDMA and WirelessHUMAN(-OFDMA) MAC profiles

This subclause defines MAC profiles for systems operating with the WirelessMAN-OFDMA and WirelessHUMAN-OFDMA air interfaces.

12.4.2.1 Basic packet PMP MAC profile

Profile identifier: OFDMA_ProfM1.

Mandatory Features:

- Support of packet CS
- Support of Internet Protocol Ipv4
- Support IEEE 802.3/Ethernet specific part
- CRC functionality shall be supported for all connections
- Support of dynamic services
- Support of BE service
- Support of nrtPS
- Support of CDMA-based initial and periodic ranging
- Support of Contention based CDMA BRs
- DFS shall be required for the license-exempt bands if mandated by regulation

12.4.2.1.1 Conventions for MAC management messages

The following rules shall be followed when reporting parameters in MAC management messages:

- Service Class Names should not be used.
- No TLVs besides HMAC Tuples shall be reported back in DSA-RSP and DSC-RSP messages.
- No TLVs besides HMAC Tuples shall be reported back in DSA-ACK messages.
- DSC-REQ messages shall not contain Request/Transmission Policy, Fixed vs. Variable Length SDU Indicator, SDU Size, ATM Switching, or Convergence Sublayer Specification TLVs.

12.4.2.1.2 MAC management message parameter transmission order

Systems implementing the profile OFDMA_ProfM1 shall transmit the TLV encoded parameters for mandatory features in the respective messages. Those systems only include the parameters listed under the respective message in its transmission of these messages plus any parameters necessary for optional features. Parameters for optional features shall occur after those listed for support of mandatory features. For the required features, the relevant parameters shall be transmitted in order of increasing Type value of the TLV key of the parameters except for the HMAC TLV, which shall be the final attribute in the TLV attribute list of the messages. Parameters with defined default values should be omitted if the desired value coincides with the default one.

12.4.3 WirelessMAN-OFDMA and WirelessHUMAN(-OFDMA) system PHY profiles

This subclause defines PHY profiles for systems operating with the WirelessMAN-OFDMA air interface and WirelessHUMAN-OFDMA air interfaces.

12.4.3.1 Common features of PHY profiles

All PHY profile shall share the common characteristics as defined in Table 639 (in 12.4.3.1.5) while individual profiles shall be differentiated by the specific characteristics listed for each profile.
If one of the PHY profiles has a parameter, which is different from the parameter defined by the common parameters section, then the values stated in the PHY profile override the value stated in the common parameters section.

12.4.3.1.1 General implementation requirements

The following optional features are not required for implementation of any PHY profiles:

- BTC
- CTC
- 64-QAM
- STC

The following features shall be supported by all PHY profiles:

- Guard time
  - BS shall be capable of using at least one allowed value.
  - SS shall be capable of detecting and using entire set of allowed values.
- Frame duration
  - SSs shall be capable of operating with any of the frame durations as defined at 8.4.5.2.

12.4.3.1.2 FDD-Specific PHY profiles features

Mandatory features:

- FDD Operation
- BS shall respect half-duplex nature of half duplex SS
- Center Frequency for UL shall be reported in the UCD channel encoding

12.4.3.1.3 TDD-Specific PHY profiles features

Mandatory features:

- TDD Operation
- Center Frequency for UL is not reported in the UCD channel encoding

12.4.3.1.4 WirelessHUMAN PHY profiles features

Mandatory features:

- TDD Operation
- Where mandated by regulation, ability to detect specific spectrum users outside limits defined by regulatory requirements
- Center Frequency for UL is not reported in the UCD channel encoding.
- Channel Nr is reported in DCD channel encoding
- Ability to switch channel within limits defined by regulatory requirements

12.4.3.1.5 Minimum performance requirements

Table 639 lists the minimum performance requirements needed for all profiles.

### 12.4.4 WirelessMAN-OFDMA RF profiles

This subclause defined RF profiles for the WirelessMAN-OFDMA and WirelessHUMAN(-OFDMA) air interfaces.

Table 649 defines the RF channels for the license bands for informative purposes. The channels shall be calculated using the following formula:

\[ F_{\text{start}} + n \cdot \Delta F_c, \forall n \in N_{\text{range}} \]

where

- \( F_{\text{start}} \) is the start frequency for the specific band
- \( \Delta F_c \) is the center frequency step
- \( N_{\text{range}} \) is the range values for the \( n \) parameter

13. MIB Modules

13.1 Structure of MIB modules

13.1.1 wmanIfMib (Obsolete)

The MIB module WMAN-IF-MIB (wmanIfMib), originally documented in the amendment IEEE Std 802.16f-2005, is obsolete and not compatible with this standard.

13.1.2 wmanDevMib

The wmanDevMib is composed of the following three groups:

- wmanDevBsObjects: contains managed objects to be implemented in the SNMP agent in BS.
- wmanDevSsObjects: contains managed objects to be implemented in the SNMP agent in SS.
- wmanDevCommonObjects: contains managed objects to be implemented in the SNMP agent in BS/SS.

Figure 313 shows the high level MIB structure of wmanDevMib for IEEE Std 802.16.

![Figure 313—wmanDevMib structure](image)

13.1.2.1 wmanDevBsObjects

Figure 314 shows the high level MIB structure of wmanDevBsObjects.

![Figure 314—wmanDevBsObjects structure](image)

13.1.2.1.1 wmanDevBsSoftwareUpgradeTable

wmanDevBsSoftwareUpgradeTable contains objects associated with BS software upgrade.

13.1.2.1.2 wmanDevBsNotification

Figure 315 shows the structure of the wmanDevBsNotification subtree that contains managed objects related to BS traps.
13.1.2.1.2.1 wmanDevBsTrapControl

wmanDevBsTrapControl is used to enable or disable BS traps.

13.1.2.1.2.2 wmanDevBsTrapDefinitions

wmanDevBsTrapDefinitions group defines all the traps reported by BS.

13.1.2.2 wmanDevSsObjects

Figure 316 shows the high level MIB structure of wmanDevSsObjects.

13.1.2.2.1 wmanDevSsConfigFileEncodingTable

wmanDevSsConfigFileEncodingTable contains configuration file information about the SS such as manufacturer, hardware model, serial number, and software or firmware revision.

13.1.2.2.2 wmanDevSsNotification

Figure 317 shows the structure of the wmanDevSsNotification subtree that contains managed objects related to the traps.

13.1.2.2.2.1 wmanDevSsTrapControl

wmanDevSsTrapControlRegister is used to enable or disable SS traps.

13.1.2.2.2.2 wmanDevBsTrapDefinitions

wmanDevBsTrapDefinitions group defines all the traps reported by SS.
13.1.2.3 wmanDevCommonObjects

Figure 318 shows the high level MIB structure of wmanDevSsObjects.

```
      wmanDevCommonObjects
        +- wmanDevCmnEventLog
        +- wmanDevCmnSnmpAgent
        +- wmanDevCmnDeviceConfig
```

Figure 318—wmanDevSsNotification structure

13.1.2.3.1 wmanDevCmnEventLog

Figure 319 shows the structure of the wmanDevCmnEventLog subtree that contains common managed objects related to the Event Log.

```
      wmanDevCmnEventLog
        +- wmanDevCmnEventLogConfigTable
        +- wmanDevCmnEventTable
        +- wmanDevCmnEventLogTable
```

Figure 319—wmanDevCmnEventLog structure

13.1.2.3.1.1 wmanDevCmnEventLogConfigTable

wmanDevCmnEventLogConfigTable defines the configurable parameters that are required for the Event Log operation.

13.1.2.3.1.2 wmanDevCmnEventTable

wmanDevCmnEventTable provides the events that are supported by BS or SS.

13.1.2.3.1.3 wmanDevCmnEventLogTable

wmanDevCmnEventLogTable is used to store local events that should reside in the nonvolatile memory.

The Event Log consists of the following features:

- Event Log uses the wrap-around buffer to store events. When the buffer is almost full, a TRAP may be sent to the NMS. When the buffer is full, the oldest entry will be removed to make room for the new entry. The wrap-around can be disabled by NMS to prevent faulty events from flooding the log buffer quickly.
- The size of the buffer is configurable.
- Events in the log have a lifespan that may be configurable.
- The threshold of the residual buffer which triggers the TRAP may be configurable.
- NMS can set the minimum severity of the events that should be logged into the buffer.
- Certain events can trigger notifications that shall be sent to NMS.
- A pointer is provided to enable access to the latest event.

The content of each entry should be retained after the power reset.
13.1.2.3.2 \textit{wmanDevCmnSnmpAgent}

Figure 320 shows the structure of the \textit{wmanDevCmnSnmpAgent} subtree that contains common managed objects related to SNMP agent configuration.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{wmanDevCmnSnmpAgent_structure}
\caption{\textit{wmanDevCmnSnmpAgent} structure}
\end{figure}

13.1.2.3.2.1 \textit{wmanDevCmnSnmpV1V2TrapDestTable}

\textit{wmanDevCmnSnmpV1V2TrapDestTable} contains the configuration objects for the BS controller entity implementing SNMP agent.

13.1.2.3.3 \textit{wmanDevCmnDeviceConfig}

\textit{wmanDevCmnDeviceConfig} contains common managed object related to device configuration.

13.1.3 \textit{wmanIf2BsMib}

Figure 321 shows the high level MIB structure of \textit{wmanIf2BsMib} for IEEE Std 802.16. The MIB structure is organized based on the FCAPS reference model.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{wmanIf2BsMib_structure}
\caption{\textit{wmanIf2BsMib} structure}
\end{figure}

13.1.3.1 \textit{wmanIf2BsFm}

Figure 322 shows the structure of the \textit{wmanIf2BsFm} subtree that contains BS traps to report fault events and exceptions, such as power status or RSSI threshold crossing.
13.1.3.1.1 wmanIf2BsTrapControl

wmanIf2BsTrapControl is used to enable or disable Base Station traps independently.

13.1.3.1.1.2 wmanIf2BsStatusTrapControlRegister

wmanIf2BsStatusTrapControlRegister is used to enable or disable Base Station status notification traps.

13.1.3.1.1.3 wmanIf2BsThresholdConfigTable

wmanIf2BsThresholdConfigTable contains threshold objects that can be set to detect the threshold crossing events.

13.1.3.1.2 wmanIf2BsTrapDefinitions

13.1.3.1.2.1 wmanIf2BsTrapPrefix

wmanIf2BsTrapPrefix lists the traps reported by the SS.

13.1.3.1.2.2 wmanIf2BsSsNotificationObjectsTable

wmanIf2BsSsNotificationObjectsTable contains SS notification objects that have been reported by the trap.

13.1.3.2 wmanIf2BsCm

Figure 323 shows the structure of the wmanIf2BsCm subtree.
13.1.3.2.1 wmanIf2BsRegisteredSsTable

wmanIf2BsRegisteredSsTable contains the basic capability information of SSs that have been negotiated and agreed between BS and SS via REG-REQ and REG-RSP messages.

13.1.3.2.2 wmanIf2BsConfigurationTable

wmanIf2BsConfigurationTable contains objects for BS system parameters and constants as defined in 10.1. wmanIf2BsConfigurationTable also contains objects that define the default behavior of the BS for 2nd Management Channel scheduling and SFID allocation as well as configuration parameters of the CPS scheduler and AAS system.

13.1.3.2.3 wmanIf2BsSsReqCapabilitiesTable

wmanIf2BsSsReqCapabilitiesTable contains the basic capability information of SSs that have been reported by SSs to BS using RNG-REQ, SBC-REQ, and REG-REQ messages.

13.1.3.2.4 wmanIf2BsSsRspCapabilitiesTable

wmanIf2BsSsRspCapabilitiesTable contains the basic capability information of SSs that have been negotiated and agreed between BS and SS via RNG-REQ/RSP, SBC-REQ/RSP, and REG-REQ/RSP messages.

13.1.3.2.5 wmanIf2BsBasicCapabilitiesTable

wmanIf2BsBasicCapabilitiesTable contains the basic capabilities of the BS as implemented in BS hardware and software. These capabilities along with the configuration for them (wmanIf2BsCapabilitiesConfigTable) are used for negotiation of basic capabilities with SS using RNG-RSP, SBC-RSP, and REG-RSP messages.

13.1.3.2.6 wmanIf2BsCapabilitiesConfigTable

wmanIf2BsCapabilitiesConfigTable contains the configuration for basic capabilities of BS. The table is intended to be used to restrict the Capabilities implemented by BS, for example in order to comply with local regulatory requirements. The BS should use the configuration along with the implemented Capabilities.
(wmanIf2BsBasicCapabilitiesTable) for negotiation of basic capabilities with SS using RNG-RSP, SBCRSP, and REG-RSP messages.

13.1.3.2.7 wmanIf2BsSsActionsTable

wmanIf2BsSsActionsTable contains all the actions specified for SSs in the standard. The actions are routed down to SS using unsolicited MAC messages: REG-RSP, DREG-REQ, PRC-LT-CTRL, and RES-CMD. The table also contains the parameters of the actions in cases where they are specified by the standard.

13.1.3.2.8 wmanIf2BsMulticastPollingTable

wmanIf2BsMulticastPollingTable contains the multicast polling group information. BS can send MCA-REQ message to assign/remove a SS to/from a multicast polling group. An entry is created when a SS is assigned to a multicast polling group; and deleted when a SS is removed from a multicast polling group.

13.1.3.2.9 wmanIf2BsMbsContentTable

wmanIf2BsMbsContentTable contains the MBS contents IDs that are used to distinguish the logical MBS connections within a MBS CID.

13.1.3.2.10 wmanIf2BsPhy

Figure 324 shows the structure of the wmanIf2BsPhy subtree that contains BS managed objects related to the Physical Layer.

```
Figure 324—wmanIf2BsPhy structure
```

13.1.3.2.10.1 wmanIf2BsCmnPhy

wmanIf2BsCmnPhy is a group containing objects common to both OFDM PHY and OFDMA PHY.
13.1.3.2.10.1.1 \textit{wmanIf2BsCmnPhyUplinkChannelTable}

\textit{wmanIf2BsCmnPhyUplinkChannelTable} contains the common channel attributes that characterize the uplink channels.

13.1.3.2.10.1.2 \textit{wmanIf2BsCmnPhyDownlinkChannelTable}

\textit{wmanIf2BsCmnPhyDownlinkChannelTable} contains the common channel attributes that characterize downlink channels.

13.1.3.2.10.2 \textit{wmanIf2BsOfdmPhy}

\textit{wmanIf2BsOfdmPhy} is a group containing objects specific to OFDM PHY.

13.1.3.2.10.2.1 \textit{wmanIf2BsOfdmUplinkChannelTable}

\textit{wmanIf2BsOfdmUplinkChannelTable} contains OFDM UCD channel attributes, defining the transmission characteristics of uplink channels.

13.1.3.2.10.2.2 \textit{wmanIf2BsOfdmDownlinkChannelTable}

\textit{wmanIf2BsOfdmDownlinkChannelTable} contains OFDM DCD channel attributes, defining the transmission characteristics of downlink channels.

13.1.3.2.10.2.3 \textit{wmanIf2BsOfdmUcdBurstProfileTable}

\textit{wmanIf2BsOfdmUcdBurstProfileTable} contains OFDM UCD burst profiles for each uplink channel.

13.1.3.2.10.2.4 \textit{wmanIf2BsOfdmDcdBurstProfileTable}

\textit{wmanIf2BsOfdmDcdBurstProfileTable} provides one row for each OFDM DCD burst profile.

13.1.3.2.10.3 \textit{wmanIf2BsOfdmaPhy}

\textit{wmanIf2BsOfdmaPhy} is a group containing objects specific to OFDMA PHY.

13.1.3.2.10.3.1 \textit{wmanIf2BsOfdmaUplinkChannelTable}

\textit{wmanIf2BsOfdmaUplinkChannelTable} contains OFDMA UCD channel attributes, defining the transmission characteristics of uplink channels.

13.1.3.2.10.3.2 \textit{wmanIf2BsOfdmaDownlinkChannelTable}

\textit{wmanIf2BsOfdmaDownlinkChannelTable} contains OFDMA DCD channel attributes, defining the transmission characteristics of downlink channels.

13.1.3.2.10.3.3 \textit{wmanIf2BsOfdmaUcdBurstProfileTable}

\textit{wmanIf2BsOfdmaUcdBurstProfileTable} contains OFDMA UCD burst profiles for each uplink channel.

13.1.3.2.10.3.4 \textit{wmanIf2BsOfdmaDcdBurstProfileTable}

\textit{wmanIf2BsOfdmaDcdBurstProfileTable} provides one row for each OFDMA DCD burst profile.
13.1.3.3 wmanIf2BsAm

Figure 325 shows the structure of the wmanIf2BsAm subtree.

![wmanIf2BsAm structure](image)

**Figure 325—wmanIf2BsAm structure**

13.1.3.3.1 wmanIf2BsOtaUsageDataRecordTable

wmanIf2BsOtaUsageDataRecordTable contains counters to keep track of the number of packets and octets that have been received or transmitted over the air interface. BS may delete some OTA UDR in wmanIf2BsOtaUsageDataRecordTable after they have been transferred to the AAA server.

13.1.3.4 wmanIf2BsPm

Figure 326 shows the structure of the wmanIf2BsPm subtree.

![wmanIf2BsPm structure](image)

**Figure 326—wmanIf2BsPm structure**

13.1.3.4.1 wmanIf2BsPmConfigurationTable

wmanIf2BsPmConfigurationTable contains the configuration of statistics information capture.

13.1.3.4.2 wmanIf2BsRssiCinrMetricsTable

wmanIf2BsRssiCinrMetricsTable contains channel measurement information on the uplink signal received from the SS, and the downlink signal reported by the SS to the BS using REP-REQ/RSP messages.
13.1.3.4.3 wmanIf2BsStartupMetricsTable

wmanIf2BsStartupMetricsTable contains statistical information that can be used to characterize SS performance during the startup.

13.1.3.4.4 wmanIf2BsThroughputMetricsTable

wmanIf2BsThroughputMetricsTable contains the average and peak data rate statistics at the BS sector level.

13.1.3.4.5 wmanIf2BsNetworkEntryMetricsTable

wmanIf2BsNetworkEntryMetricsTable contains the statistics for the network entry and network re-entry.

13.1.3.4.6 wmanIf2BsPacketErrorRateTable

wmanIf2BsPacketErrorRateTable contains the statistics for the packet error rate.

13.1.3.4.7 wmanIf2BsHandoverMetricsTable

wmanIf2BsHandoverMetricsTable contains statistical information that can be used to characterize MS performance during the handover.

13.1.3.4.8 wmanIf2BsUserMetricsTable

wmanIf2BsUserMetricsTable contains counter objects to track user metrics.

13.1.3.4.9 wmanIf2BsCidMetricsTable

wmanIf2BsCidMetricsTable tracks the number of basic and primary CIDs, and the average and maximum number of user CIDs.

13.1.3.4.10 wmanIf2BsServiceFlowMetricsTable

wmanIf2BsServiceFlowMetricsTable contains counter objects to track the number of DSx REQ success rate, IP address success, and number of SFID allocated, and peak DL/UL service flows.

13.1.3.4.11 wmanIf2BsArqHarqMetricsTable

wmanIf2BsArqHarqMetricsTable contains objects that are used to measure the ARQ/HARQ performance.

13.1.3.4.12 wmanIf2BsAuthenticationMetricsTable

wmanIf2BsAuthenticationMetricsTable contains counters used to count on receipt of non-authentic messages so that an active attack can be detected.

13.1.3.5 wmanIf2BsSm

Figure 327 shows the structure of the wmanIf2BsSm subtree that contains BS managed objects related to the MAC privacy management entity.
13.1.3.5.1 `wmanIf2BsPkmSecurityCapabilityTable`

`wmanIf2BsPkmSecurityCapabilityTable` contains the list of the cryptographic suite(s) an BS supports.

13.1.3.5.2 `wmanIf2BsSsPkmSecurityCapabilityTable`

`wmanIf2BsSsPkmSecurityCapabilityTable` contains the SS’s Security Capabilities that are conveyed by the “Auth Request” message. It contains the list of the cryptographic suite(s) an SS supports.

13.1.3.5.3 `wmanIf2BsPkmV1Objects`

13.1.3.5.3.1 `wmanIf2BsPkmV1ConfigTable`

`wmanIf2BsPkmV1ConfigTable` contains the configuration of the PKM attributes that are to be used for BS and all SSs that are connected to such BS.

13.1.3.5.3.2 `wmanIf2BsSsPkmV1AuthorizationTable`

`wmanIf2BsSsPkmV1AuthorizationTable` contains information related to SS’s authorization process.

13.1.3.5.3.3 `wmanIf2BsSsPkmV1TekTable`

`wmanIf2BsSsPkmV1TekTable` contains the TEK attributes that are associated with each SAID.

13.1.3.5.4 `wmanIf2BsPkmV2Objects`

13.1.3.5.4.1 `wmanIf2BsPkmV2ConfigTable`

`wmanIf2BsPkmV2ConfigTable` contains the PKM attributes that are needed for PKM operation.
13.1.3.5.4.2 wmanIf2BsSsPkmV2RsaAuthTable

wmanIf2BsSsPkmV2RsaAuthTable contains information related to PKMV2 RSA based authorization process.

13.1.3.5.4.3 wmanIf2BsSsPkmV2TekTable

wmanIf2BsSsPkmV2TekTable contains the TEK attributes that are associated with each SAID.

13.1.3.5.4.4 wmanIf2BsSsPkmV23wayHandshakeTable

This table contains information related to PKMV2 3-way handshake process.

13.1.4 wmanIf2mBsMib

Figure 328 shows the high level MIB structure of the wmanIf2mBsMib for IEEE 802.16. The MIB structure is organized based on the FCAPS reference model.

![Figure 328—wmanIf2mBs structure](image)

13.1.4.1 wmanIf2mBsCm

Figure 329 shows the structure of the wmanIf2mBsCm subtree.

![Figure 329—wmanIf2mBsCm structure](image)

13.1.4.1.1 wmanIf2mBsConfiguration

Figure 330 shows the structure of the wmanIf2mBsConfiguration subtree.
Figure 330—wmanIf2mBsConfiguration structure

13.1.4.1.1.1 wmanIf2mBsConfigurationTable

wmanIf2mBsConfigurationTable contains objects for BS system parameters and constants as defined in 10.1.

13.1.4.1.1.2 wmanIf2mBsSsReqCapabilitiesTable

wmanIf2mBsSsReqCapabilitiesTable contains the basic capability information of SSs that have been reported by SSs to BS using RNG-REQ, SBC-REQ and REG-REQ messages.

13.1.4.1.1.3 wmanIf2mBsSsRspCapabilitiesTable

wmanIf2mBsSsRspCapabilitiesTable contains the basic capability information of SSs that have been negotiated and agreed between BS and SS via RNG-REQ/RSP, SBC-REQ/RSP and REG-REQ/RSP messages.

13.1.4.1.1.4 wmanIf2mBsBasicCapabilitiesTable

wmanIf2mBsBasicCapabilitiesTable contains the basic capabilities of the BS as implemented in BS hardware and software. These capabilities along with the configuration for them (wmanIf2mBsCapabilitiesConfigTable) are used for negotiation of basic capabilities with SS using RNG-RSP, SBC-RSP and REG-RSP messages.

13.1.4.1.1.5 wmanIf2mBsCapabilitiesConfigTable

wmanIf2mBsCapabilitiesConfigTable contains the configuration for basic capabilities of BS. The table is intended to be used to restrict the Capabilities implemented by BS, for example in order to comply with local regulatory requirements. The BS should use the configuration along with the implemented Capabilities (wmanIf2mBsBasicCapabilitiesTable) for negotiation of basic capabilities with SS using RNG-RSP, SBCRSP, and REG-RSP messages.

13.1.4.1.1.6 wmanIf2mBsSsCidUpdateTable

wmanIf2mBsSsCidUpdateTable contains the “CID update” TLV that is sent in the REG-RSP message to allow an MS to update its service flows and connection information so that it may continue service after a handover to a new serving BS.
13.1.4.1.1.7 wmanIf2mBsNetworkServiceProviderTable

wmanIf2mBsNetworkServiceProviderTable contains the list of NetworkService Provider to be sent by SBC-RSP or broadcast by SII-ADV message.

13.1.4.1.2 wmanIf2mBsPowerSavingMode

Figure 331 shows the structure of the wmanIf2mBsPowerSavingMode subtree.

```
  wmanIf2mBsPowerSavingMode
   -- wmanIf2mBsSsPwrSaving2CidMapTable
   -- wmanIf2mBsSsPowerSavingClassesTable
```

**Figure 331—wmanIf2mBsPowerSavingMode structure**

13.1.4.1.2.1 wmanIf2mBsSsPwrSaving2CidMapTable

wmanIf2mBsSsPwrSaving2CidMapTable contains the power saving status for each CID in an SS.

13.1.4.1.2.2 wmanIf2mBsSsPowerSavingClassesTable

wmanIf2mBsSsPowerSavingClassesTable contains the power saving classes definitions, and activation/deactivation information that are provided by MOB_SLP-REQ and MOB_SLP-RSP messages.

13.1.4.1.3 wmanIf2mBsNeighborAdv

Figure 332 shows the structure of the wmanIf2mBsNeighborAdv subtree.

```
  wmanIf2mBsNeighborAdv
   -- wmanIf2mBsNeighborAdvCommonTable
   -- wmanIf2mBsNeighborAdvertizementTable
   -- wmanIf2mBsNeighborOfdmaUcdTable
   -- wmanIf2mBsNeighborOfgmaDcdTable
   -- wmanIf2mBsLbsAdvNeighborBsTable
```

**Figure 332—wmanIf2mBsNeighborAdv structure**

13.1.4.1.3.1 wmanIf2mBsNeighborAdvCommonTable

wmanIf2mBsNeighborAdvCommonTable contains the common attributes for the MOB_NBR-ADV message.

13.1.4.1.3.2 wmanIf2mBsNeighborAdvertizementTable

wmanIf2mBsNeighborAdvertizementTable contains the attributes specific to each neighbor BS for the MOB_NBR-ADV message.
13.1.4.1.3.3 wmanIf2mBsNeighborBsOfdmaUcdTable

wmanIf2mBsNeighborBsOfdmaUcdTable contains the attributes of the UCD message for the neighboring BSs. It provides one row for each neighboring BS.

13.1.4.1.3.4 wmanIf2mBsNeighborBsOfdmaDcdTable

wmanIf2mBsNeighborBsOfdmaDcdTable contains the attributes of the DCD message for the neighboring BSs. It provides one row for each neighboring BS.

13.1.4.1.3.5 wmanIf2mBsLbsAdvNeighborBsTable

wmanIf2mBsNeighborBsOfdmaDcdTable contains the attributes that are broadcast in the LBS-ADV message.

13.1.4.1.4 wmanIf2mBsPaging

Figure 333 shows the structure of the wmanIf2mBsPaging subtree.

```
wmanIf2mBsPaging
   +--- wmanIf2mBsPagingAdvertizementTable
   +--- wmanIf2mBsMsPagedTable
   +--- wmanIf2mBsPagingGroupsTable
```

Figure 333—wmanIf2mBsPaging structure

13.1.4.1.4.1 wmanIf2mBsPagingAdvertizementTable

wmanIf2mBsPagingAdvertizementTable contains the attributes that BS broadcasts in the MOB_PAG-ADV message.

13.1.4.1.4.2 wmanIf2mBsMsPagedTable

wmanIf2mBsMsPagedTable contains the MSs that are paged in the MOB_PAG-ADV message.

13.1.4.1.4.3 wmanIf2mBsPagingGroupsTable

wmanIf2mBsPagingGroupsTable contains paging group IDs that BS can broadcast in the MOB_PAG-ADV message.

13.1.4.1.5 wmanIf2mBsServiceFlow

Figure 334 shows the structure of the wmanIf2mBsServiceFlow subtree.
**Figure 334—wmanIf2mBsServiceFlow structure**

13.1.4.1.5.1 *wmanIf2mBsServiceFlowTable*

*wmanIf2mBsServiceFlowTable* contains the service flow database. When an SS first registers at the BS, the BS should download the SSs’ service flow profile (e.g. QoS parameter set and classification rules) from the home AAA server.

For portable or mobile SS, when the SS hands over to another BS, as part of the context transfer, the serving BS should transfer the SSs’ service flows to the target BS. After the handover, the old serving BS shall change the *wmanIf2BsServiceFlowState* of the service flows, previously used by the SS to ‘inactive.’ The BS may cleanup *wmanIf2BsServiceFlowTable* periodically, by removing those entries with *wmanIf2BsServiceFlowState* = ‘inactive.’

13.1.4.1.5.2 *wmanIf2mBsClassifierRuleTable*

*wmanIf2mBsClassifierRuleTable* contains packet classifier rules associated with service flows.

13.1.4.1.5.3 *wmanIf2mBsPhsRuleTable*

*wmanIf2mBsPhsRuleTable* contains PHS rule dictionary entries. Each entry contains the data of the header to be suppressed along with its identification—PHSI.

13.1.4.1.5.4 *wmanIf2mBsQoSProfileTable*

*wmanIf2mBsQoSProfileTable* contains QoS profiles that are associated with service flows or CIDs via the *wmanIf2mBsQoSProfileIndex*.

13.1.4.1.5.5 *wmanIf2mBsArqAttributeTable*

*wmanIf2mBsArqAttributeTable* contains ARQ parameters that are associated with the Service Flows.

13.1.4.2 *wmanIf2mBsPm*

Figure 335 shows the structure of the *wmanIf2mBsPm* subtree.
13.1.4.2.1 \texttt{wmanIf2mBsSsSleepModeStatisticsTable}

\texttt{wmanIf2mBsSsSleepModeStatisticsTable} contains the sleep mode statistic for SS.

13.1.4.2.2 \texttt{wmanIf2mBsMobileScanRequestTable}

\texttt{wmanIf2mBsMobileScanRequestTable} contains the attributes that are sent in the MOB_SCN-REQ message.

13.1.4.2.3 \texttt{wmanIf2mBsMobileScanResponseTable}

\texttt{wmanIf2mBsMobileScanResponseTable} contains the attributes that are sent in the MOB_SCN-RSP message.

13.1.4.2.4 \texttt{wmanIf2mBsNeighborBsInfoTable}

\texttt{wmanIf2mBsNeighborBsInfoTable} contains the neighbor BS information that is sent in the MOB_SCN-RSP and MOB_SCN-REP messages.

13.1.4.2.5 \texttt{wmanIf2mBsDiversity BsInfoTable}

\texttt{wmanIf2mBsDiversity BsInfoTable} contains the diversity BS information that is sent in the MOB_SCN-REP messages.

13.1.5 \texttt{wmanIf2fBsMib}

Figure 336 shows the high level MIB structure of \texttt{wmanIf2fBsMib}.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig335.png}
\caption{\texttt{wmanIf2mBsPm} structure}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig336.png}
\caption{\texttt{wmanIf2fBsMib} structure}
\end{figure}
13.1.5.1 wmanIf2fBsProvServiceFlowTable

wmanIf2fBsProvServiceFlowTable contains service flow provisioned by NMS.

13.1.5.2 wmanIf2fBsProvServiceClassTable

wmanIf2fBsProvServiceClassTable contains QoS parameter set, as defined in subclause 6.3.14 and 11.13. This table is provisioned by NMS.

13.1.5.3 wmanIf2fBsServiceFlowTable

wmanIf2fBsServiceFlowTable contains the service flow database. The table reports each service flow created between BS and SS, its associated CID and all the QoS parameters used.

13.1.5.4 wmanIf2fBsProvClassifierRuleTable

wmanIf2fBsProvClassifierRuleTable contains the packet classifier rules associated with service flows. This table is provisioned by NMS.

13.1.5.5 wmanIf2fBsProvPhsRuleTable

wmanIf2fBsProvPhsRuleTable contains PHS rule dictionary entries. Each entry contains the data of the header to be suppressed along with its identification—PHSI. This table is provisioned by NMS.

13.1.5.6 wmanIf2fBsClassifierRuleTable

wmanIf2fBsClassifierRuleTable contains the properties of classification rules of created service flows.

13.1.5.7 wmanIf2fBsPhsRuleTable

wmanIf2fBsPhsRuleTable contains the properties of PHS rules of created service flows.

13.1.6 wmanIf2SsMib

Figure 337 shows the high level MIB structure of the wmanIf2SsMib.

```
Figure 337—wmanIf2SsMib structure
```

wmanIf2SsMib
  └── wmanIf2SsConfigurationTable
  │   └── wmanIf2mSsConfigurationTable

          └── wmanIf2SsTrapPrefix
              └── wmanIf2SsNotificationObjectsTable
13.1.6.1 wmanIf2SsConfigurationTable

wmanIf2SsConfigurationTable contains objects for SS system parameters and constants as defined in 10.1.

13.1.6.2 wmanIf2mSsConfigurationTable

wmanIf2mSsConfigurationTable contains objects for SS system parameters and constants as defined in 10.1.

13.1.6.3 wmanIf2SsTrapControl

13.1.6.3.1 wmanIf2SsTrapControlRegister

wmanIf2SsTrapControlRegister is used to enable or disable Subscriber Station traps.

13.1.6.3.2 wmanIf2SsThresholdConfigTable

wmanIf2SsThresholdConfigTable contains threshold objects that can be set to detect the threshold crossing events.

13.1.6.4 wmanIf2SsTrapDefinitions

13.1.6.4.1 wmanIf2SsTrapPrefix

wmanIf2SsTrapPrefix lists the traps reported by the SS.

13.1.6.4.2 wmanIf2SsNotificationObjectsTable

wmanIf2SsNotificationObjectsTable contains SS notification objects that have been reported by the trap.

13.1.7 wmanIf2TcMib

wmanIf2TcMib defines TEXTUAL-CONVENTION to be imported by wmanIf2Mib modules.

13.2 ASN.1 Definitions of MIB Modules

13.2.1 wmanIfMib (Obsolete)

The MIB module WMAN-IF-MIB (wmanIfMib) was documented in the amendment IEEE 802.16f-2005. It is not documented here as obsolete and not compatible with this revision of the standard.

13.2.2 wmanDevMib

STATUS    current
DESCRIPTION
  "This error code provides further information about an
  Authorization Reject, Key Reject, Authorization Invalid,
  or TEK Invalid.

  0 - no failure
  1 - unauthorized SS
  2 - unauthorized SAID
  3 - unsolicited
  4 - invalid key sequence
  5 - key request authentication failure

  The following are error code for permanent authorization
  failure that indicates any reattempts at authorization
  would continue to result in Authorization Rejects.

  6 - the BS does not have the CA certificate belonging
     to the issuer of an SS certificate
  7 - SS certificate has an invalid signature
  8 - ASN.1 parsing failure during verification of SS
     certificate
  9 - SS certificate is on the 'hot list'
 10 - inconsistencies between certificate data and data
     in accompanying PKM attributes
 11 - SS and BS have incompatible security capabilities"

-- Textual convention for capabilities encodings
WmanIf2CurrentTxPower ::= TEXTUAL-CONVENTION
   STATUS current
   DESCRIPTION
   "The average parameter indicates the transmitted power used for the burst that carried the message. The parameter is reported in dBm and is quantized in 0.5 dBm steps ranging from -84 dBm (encoded 0x00) to 43.5 dBm (encoded 0xFF). Values outside this range shall be assigned the closest extreme. The parameter is only applicable to systems supporting the OFDM, or OFDMA PHY specifications. However, for the OFDM or OFDMA PHY, this value indicates the average transmitted power of each subcarrier for the burst which carried the message. However, for the OFDM or OFDMA PHY, this value indicates the average transmitted power of each subcarrier for the burst which carried the message."

STATUS      current
DESCRIPTION
    "This table contains the configuration for basic
    capabilities of BS. The table is intended to be used to
    restrict the Capabilities implemented by BS, for example in
    order to comply with local regulatory requirements. The BS
    should use the configuration along with the implemented
    Capabilities (wmanIf2BsBasicCapabilitiesTable) for
    negotiation of basic capabilities with SS using RNG-RSP,
    SBC-RSP and REG-RSP messages. The negotiated capabilities
    are obtained by interSubclause of SS reported capabilities,"
BS raw capabilities and BS configured capabilities. The objects in the table have read-write access. The rows are created by BS as a copy of wmanIf2BsBasicCapabilitiesTable and can be modified by NMS.

DESCRIPTION
"This MIB Module defines managed objects for Base Station
based on IEEE Std 802.16. The MIB contains managed objects
that are specific to mobile Broadband Wireless Networks."

               omitQosRelatedField(3)}

WmanIf2mNbrBsId ::= TEXTUAL-CONVENTION
STATUS current
DESCRIPTION "The least significant 24 bits of the Base Station ID"
parameter in the DL-MAP message broadcast by the Neighbor BS. The BSID is a 6 byte number and follows the encoding rules of MacAddress textual convention, i.e. as if it were transmitted least-significant bit first. The value should be displayed with 2 parts clearly separated by a colon. Example 001DFF:00003A - 00003A is the Base Station ID."

REFERENCE
"Subclause 6.3.2.3.42"

SYNTAX OCTET STRING (SIZE(3))

WmanIf2mNbrOperatorId ::= TEXTUAL-CONVENTION
STATUS current
DESCRIPTION
"The most significant 24 bits of the Base Station ID parameter in the DL-MAP message broadcast by the Neighbor BS. The BSID is a 6 byte number and follows the encoding rules of MacAddress textual convention, i.e. as if it were transmitted least-significant bit first. The value should be displayed with 2 parts clearly separated by a colon. Example 001DFF:00003A - 001DFF is the Operator ID."

REFERENCE
"Subclause 6.3.2.3.42"

SYNTAX OCTET STRING (SIZE(3))

WmanIf2mPhyProfileId ::= TEXTUAL-CONVENTION
STATUS current
DESCRIPTION
"For systems using OFDM or OFDMA, the definition of the PHY Profile ID is shown as follows:
bit 0: If set to 1, BS (or FA) is co-located with the serving BS
bit 1: If set to 1, the BS has the same number of FAs and frequencies as the BS broadcasting the NBR-ADV
bit 2: 0b00 = Unsynchronized
bit 2: 0b01 = Time synchronization
bit 2: 0b10 = Time and Frequency synchronization
If time synchronization is indicated for the OFDMA PHY, then the downlink frames transmitted by the serving BS and the Neighbor BS shall be synchronized to a level of at least 1/8 cyclic prefix length. If frequency synchronization is indicated for the OFDMA PHY, then the BS reference clocks shall be synchronized to a level that yields RF center frequency offset of no more than 1% of the OFDMA carrier spacing of the Neighbor BS.
bit 4: If set to 1, the BS EIRP follows the PHY Profile ID
bit 5: 0b0- The DCD/UCD settings of this neighbor BS are the same as those of the serving BS unless the TLV information specifies.
0b1- The DCD/UCD settings of this neighbor BS are the same as those of the preceding neighbor BS unless the TLV information specifies.
bit 6: If set to 1, the FA Index follows the PHY Profile ID. In addition, if the FA Indicator is followed, the DL
center frequency shall be omitted in the DCD/UCD difference TLV information.

bit 7: The Trigger Reference Indicator is related to the Neighbor BS trigger metric TLV information of this neighbor BS.
0b0- The trigger settings of this neighbor BS are the same as those provided by the serving BS (via DCD). If the TLV information is present, it overrides values inherited from preceding neighbor BS.
0b1- The trigger settings of this neighbor BS are the same as those of the preceding neighbor BS."

REFERENCE
"Subclause 6.3.2.3.42, Table 144"

SYNTAX

    triggRefInd(7)}

WmanIf2mHoProcOptm ::= TEXTUAL-CONVENTION
STATUS current
DESCRIPTION
"For each Bit location, a value of '0' indicates the associated reentry management messages shall be required, a value of '1' indicates the reentry management message may be omitted. Regardless of the HO Process Optimization TLV settings, the target BS may send unsolicited SBC-RSP and/ or REG-RSP management messages
bit 0: Omit SBC-REQ/RSP management messages during re-entry processing
bit 1: Omit PKM Authentication phase except TEK phase during current re-entry processing
bit 2: Omit PKM TEK creation phase during reentry processing
bit 3: Omit REG-REQ/RSP management during current re-entry processing
bit 4: Omit Network Address Acquisition management messages during current reentry processing
bit 5: Omit Time of Day Acquisition management messages during current reentry processing
bit 6: Omit TFTP management messages during current re-entry processing
bit 7: Full service and operational state transfer or sharing between serving BS and target BS (ARQ, timers, counters, MAC state machines, etc...)
"

MAX-ACCESS not-accessible
STATUS current
DESCRIPTION
"This table contains the service flow database. When an SS first registers at the BS, the BS should download the SS' service flow profile (e.g. QoS parameter set and classification rules) from the home AAA server.

For fixed or normadic SS, its service flow profile will not be changed in the entire duration of the session.

For portable or mobile SS, when the SS handoffs to another BS, as part of the context transfer, the serving BS should transfer service flow profile to the target BS. After the handoff, the old serving BS shall change the wmanIf2mBsServiceFlowState of the service flows, previously used by the SS to 'inactive'.

The BS may cleanup wmanIf2mBsServiceFlowTable periodically, by removing those entries with wmanIf2mBsServiceFlowState = 'inactive'."

wmanIf2mBsClassifierRuleEnetType OBJECT-TYPE
SYNTAX WmanIf2TcEthernetType
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"This object indicates the format of the layer 3 protocol
id in the Ethernet packet. A value of none(0) means that
the rule does not use the layer 3 protocol type as a
matching criteria. A value of ethertype(1) means that the
rule applies only to frames which contains an EtherType
value. Ethertype values are contained in packets using
the Dec-Intel-Xerox (DIX) encapsulation or the RFC1042
Sub-Network Access Protocol (SNAP) encapsulation formats.
A value of dsap(2) means that the rule applies only to
frames using the IEEE802.3 encapsulation format with a
Destination Service Access Point (DSAP) other than 0xAA
(which is reserved for SNAP). If the Ethernet frame
contains an 802.1P/Q Tag header (i.e. EtherType 0x8100),
this object applies to the embedded EtherType field within
the 802.1P/Q header. If the referenced parameter is not
present in a classifier, this object reports the value of
0."

SYNTAX Integer32 (0..65535)
MAX-ACCESS read-only
STATUS current
DESCRIPTION
"If wmanIf2mBsClassifierRuleEnetType is none(0), this
object is ignored when considering whether a packet matches
the current rule. If wmanIf2mBsClassifierRuleEnetType is
ethertype(1), this object gives the 16-bit value of the
EtherType that the packet must match in order to match the
rule. If wmanIf2mBsClassifierRuleEnetType is dsap(2), the
lower 8 bits of this object's value must match the DSAP
byte of the packet in order to match the rule.
If the Ethernet frame contains an 802.1P/Q Tag header
(i.e. EtherType 0x8100), this object applies to the
embedded EtherType field within the 802.1P/Q header."
If the referenced parameter is not present in the classifier, the value of this object is reported as 0.

-- Mobile Station Sleep Mode Statistics Table
--

wmanIf2mBsSsSleepModeStatisticsTable OBJECT-TYPE
SYNTAX      SEQUENCE OF WmanIf2mBsSsSleepModeStatisticsEntry
MAX-ACCESS  not-accessible
STATUS      current
DESCRIPTION
"This table contains the sleep mode statistic for MS. This
table shall be maintained as FIFO to store the sleep mode
statistics over a period of time that is subject to
implementation. This statistics information can be to
monitor, fine tuning, or debugging the power saving
performance of each MS. When the statistics entry for an
MS reaches the limit, it wraps around to the beginning, and
overwrites the oldest entry with the new entry. When the BS
roams to a different BS, all entries associated with such
MS will be deleted."

   MAX-ACCESS  read-create
   STATUS      current
   DESCRIPTION
      "This object indicates the format of the layer 3 protocol id in the Ethernet packet. A value of none(0) means that the rule does not use the layer 3 protocol type as a matching criteria. A value of ethertype(1) means that the rule applies only to frames which contains an EtherType value. Ethertype values are contained in packets using the Dec-Intel-Xerox (DIX) encapsulation or the RFC1042 Sub-Network Access Protocol (SNAP) encapsulation formats. A value of dsap(2) means that the rule applies only to frames using the IEEE802.3 encapsulation format with a Destination Service Access Point (DSAP) other than 0xAA (which is reserved for SNAP). If the Ethernet frame contains an 802.1P/Q Tag header (i.e. EtherType 0x8100), this object applies to the embedded EtherType field within the 802.1P/Q header. If the referenced parameter is not present in a classifier, this object reports the value of 0."

wmanIf2fBsClassifierRuleEnetProtocolTyp OBJECT-TYPE
SYNTAX      WmanIf2TcEthernetType
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION
  "This object indicates the format of the layer 3 protocol
   id in the Ethernet packet. A value of none(0) means that
   the rule does not use the layer 3 protocol type as a
   matching criteria. A value of ethertype(1) means that the
   rule applies only to frames which contains an EtherType
   value. Ethertype values are contained in packets using
   the Dec-Intel-Xerox (DIX) encapsulation or the RFC1042
   Sub-Network Access Protocol (SNAP) encapsulation formats.
   A value of dsap(2) means that the rule applies only to
   frames using the IEEE802.3 encapsulation format with a
   Destination Service Access Point (DSAP) other than 0xAA
   (which is reserved for SNAP). If the Ethernet frame
   contains an 802.1P/Q Tag header (i.e. EtherType 0x8100),
   this object applies to the embedded EtherType field within
   the 802.1P/Q header. If the referenced parameter is not
   present in a classifier, this object reports the value of
   0."
REFERENCE
  "Subclause 11.13.18.3.3.10"
::= { wmanIf2fBsClassifierRuleEntry 16 }

wmanIf2fBsClassifierRuleEnetProtocol OBJECT-TYPE
SYNTAX      Integer32 (0..65535)
MAX-ACCESS  read-only
STATUS      current
DESCRIPTION  "If wmanIf2CmnClassifierRuleEnetProtocolTyp is none(0),
this object is ignored when considering whether a packet
matches the current rule.
If wmanIf2CmnClassifierRuleEnetProtocolTyp is ethertype(1)
, this object gives the 16-bit value of the EtherType that
the packet must match in order to match the rule.
If wmanIf2CmnClassifierRuleEnetProtocolTyp is dsap(2), the
lower 8 bits of this object's value must match the DSAP
byte of the packet in order to match the rule.
If the Ethernet frame contains an 802.1P/Q Tag header
(i.e. EtherType 0x8100), this object applies to the
embedded EtherType field within the 802.1P/Q header.
If the referenced parameter is not present in the
classifier, the value of this object is reported as 0."

WmanIf2TcBsIdType ::= TEXTUAL-CONVENTION
 STATUS current
 DESCRIPTION
 "Defines the encoding of BSID. The BSID is a 6 byte number
 and follows the encoding rules of MacAddress textual
 convention, i.e. as if it were transmitted
 least-significant bit first. The value should be displayed
 with 2 parts clearly separated by a colon e.g:
 001DFF:00003A. The most significant part is representing
 the Operator ID."

                  unsolicitedGrantService(6)}

WmanIf2TcGlobalSrvClass ::= TEXTUAL-CONVENTION
  STATUS current
  DESCRIPTION
  "Global Service Class Name contains 8 information fields
  that map to predefined QoS attributes as shown in
  subclause 6.3.14.4.1.

  bit 0: Uplink/Downlink indicator
         0 - uplink
         1 - downlink
  bit 1-6: Maximum sustained traffic rate in bps that is
           defined in Table 124b
  bit 7:  0 - no traffic indication
1 - traffic indication

bit 8-13: Maximum traffic burst defines the maximum burst size that must be accommodated for the service.

bit 14-19: Minimum reserved traffic rate parameter specifies the minimum rate, in bits per second, reserved for this service flow.

bit 20-25: Maximum latency specifies the maximum interval between the reception of a packet at CS of BS or SS and the arrival of the packet to the peer device.

bit 26: SDU indicator specifies whether the SDUs on the service flow are fixed-length or variable-length.
   0 - variable length
   1 - fixed length

bit 27: Paging indicator of an MS preference for the reception of paging advisory messages during idle mode. When set, it indicates that the BS may present paging advisory messages or other indicative messages to the MS when data SDUs bound for the MS are present while the MS is in Idle Mode.
   0 - no paging generation
   1 - paging generation

bit 28-35: Req/Tx Policy - An attribute is enabled by setting the corresponding bit position to 1. For attributes affecting UL BR types, a value of zero indicates the default actions described in the scheduling service description in 6.3.5 shall be used. A value of 1 indicates that the action associated with the attribute bit overrides the default action.
   bit28: No broadcast BR opportunities. (UL only)
   bit29: No use multicast BR opportunities. (UL only)
   bit30: No piggyback requests with data. (UL only)
   bit31: No fragment data.
   bit32: No suppress payload headers (CS parameter).
   bit33: No pack multiple SDUs (or fragments) into single MAC PDUs.
   bit34: Not include CRC in the MAC PDU.
   bit35: Reserved
   bit 36-38: The value of this parameter specifies the UL grant scheduling type that shall be enabled for the associated UL service flow (see 6.3.5.2).
   Value = 1: Undefined (BS implementation-dependenta)
   2: BE (default)
   3: nrtPS
   4: rtPS
   5: Extended rtPS
   6: UGS"

14. Management interfaces and procedures

This subclause defines the service primitives for use at C-SAP and M-SAP at BS and MS side of the radio interface. The specific mapping of service primitives to protocol messages in the backhaul network is out of scope of this standard.

14.1 Service primitive template

14.1.1 Universal naming schema for SAP service primitive

The primitive name defined on the SAP consists of three fields—SAP, Function, and Operation:

- **SAP**
  - C—Control plane SAP
  - M—Management plane SAP

- **Function**
  - ACM—Accounting Management
  - HO—Handover
  - IMM—Idle Mode Management
  - LBS—Location Based Services
  - MBS—Multicast Broadcast Service
  - NEM—Network Entry Management
  - RRM—Radio Resource Management
  - SFM—Service Flow Management
  - SM—Security Management
  - SMC—Secondary Management Connection
  - SSM—Subscriber Station Management

- **Operation**
  - REQ—Request
  - RSP—Response to the REQ message
  - ACK—Acknowledgement to the reception of REQ or RSP or IND message
  - IND—Event Notification

These primitives are symmetrical between the IEEE 802.16 entity and the NCMS. That is, both the IEEE 802.16 entity (SS/MS or BS) and the NCMS can send these primitives depending on the functional behavior defined for M-SAP and C-SAP. ACK shall only be supported across the C-SAP.

- A service primitive of type REQ is used whenever a response to the primitive is solicited. If there is a REQ message on the radio interface, it is generally mapped to a REQ on C-SAP/M-SAP.
- A service primitive of type RSP is used in response to a REQ primitive. Moreover, if there is a RSP message on the radio interface, it is generally mapped to a RSP on C-SAP/M-SAP.
- A service primitive of type IND is used at C-SAP or M-SAP for event notification if a response to this primitive is not solicited, and if the primitive is not sent in response to a REQ primitive.
- A service primitive of type ACK can be used to acknowledge the receipt of a C-SAP primitive of type REQ, RSP, or IND.

The specific usage of these operation types for the respective control and management functions is specified in the subsequent subclauses.

The IEEE 802.16 entity shall support the primitives which are delivered through C-SAP or M-SAP interfacing with NCMS.
14.1.2 SAP service primitive object format

There are two types of services: M-SAP/C-SAP operation service primitive and M-SAP/C-SAP notification service primitive. The REQ and RSP operations shall use the operation service primitive and the IND operation shall use the notification service primitive. The ACK operation shall use the same primitive format as the primitive it acknowledges.

14.1.2.1 M-SAP/C-SAP operation service primitive

This primitive is defined as Primitive_name () with a parameter list.

The format shall be:

```
Primitive_name
    (
        Operation_Type,
        Action_Type,
        Destination,
        Attribute_list
    )
```

The parameters shall be described briefly in Table 650.

### Table 650—M-SAP/C-SAP Operation Types

<td>Array of pair (Attribute_ID, Attribute_value). In Get request operation, Attribute_value is Null</td>
</tr>
</tbody>
</table>
14.1.2.2 M-SAP/C-SAP notification service primitive:

This primitive shall be defined as Primitive_name () with a parameter list.

The format shall be:

```
Primitive_name
    (Event_Type, Destination, Attribute_List)
```

The parameters are described briefly in Table 651.

</tbody>
</table>

14.1.3 SAP service primitive flow diagram template

Four typical handshake scenarios shown in Figure 338. The procedures are applicable to BS and SS side.
14.2 Management and control functions

14.2.1 Accounting management

Accounting event can be detected for an SS Network Entry. Since each SS can have multiple connections at the same time, accounting event for each connection should be detected. Accounting for an SS Network Entry is initiated when the SS registers at the network and terminated when the SS deregisters from the network. Similarly, accounting for a connection is initiated at the dynamic service addition (DSA) instant of the connection and terminated at the dynamic service deletion (DSD) instant of the connection. Accounting management uses the AAA Services in the NCMS.

14.2.1.1 Accounting procedure

Accounting primitives consist of M-ACM-IND, M-ACM-REQ and M-ACM-RSP, as shown in Figure 339 and Figure 340. Figure 339 represents accounting primitives initiated by a BS when it receives REG-REQ, DREG-REQ, DSA-REQ/RSP, DSC-REQ/RSP, or DSD-REQ/RSP. Figure 340 represents accounting primitives initiated by the NCMS.
Figure 339—Accounting primitive initiated by a BS

Figure 340—Accounting primitives initiated by the NCMS
14.2.1.2 Service primitives for accounting management

14.2.1.2.1 M-ACM-REQ

14.2.1.2.1.1 Function

This primitive can be issued by the NCMS to retrieve the accounting records from BS.

14.2.1.2.1.2 Semantics of the service primitive

The parameters of the primitive are as follows:

\[
\text{M-ACM-REQ} \left( 
\quad \text{Operation Type: Get,} \\
\quad \text{Destination: BS,} \\
\quad \text{Attribute List:} \\
\quad \quad \text{SS MAC Address,} \\
\quad \quad \text{Service Flow Identifier,} \\
\quad \quad \text{Accounting Record Number,} \\
\quad \quad \text{Accounting Correlation Index} \\
\right)
\]

**SS MAC Address**
48-bit MAC address which identifies SS

**Service Flow identifier**
32-bit service flow identifier which will identify service flows of an SS

**Accounting Record Number**
Identifies accounting record within one session

**Accounting Correlation Index**
Provides a unique correlation index for generated records. This field can contain the Account Session ID or the Account-Multi-Session ID that is typically used by the AAA server to consolidate the session records.

14.2.1.2.1.3 When generated

This primitive can be generated at the NCMS to request accounting event from a BS.

14.2.1.2.1.4 Effect of receipt

Upon receiving this primitive from NCMS, the BS shall gather accounting information and return the information using the M-ACM-RSP primitive.

14.2.1.2.2 M-ACM-RSP

14.2.1.2.2.1 Function

This primitive is issued by a BS to respond to M-ACM-REQ.

14.2.1.2.2.2 Semantics of the service primitive

The parameters of the primitive are as follows:
M-ACM-RSP

(Operation_Type: Get,
Destination: NCMS,
Attribute_List:
    SS MAC Address,
    Service Flow Identifier,
    Accounting Record Number,
    Accounting Octets,
    Accounting Packets,
    Service Flow Information,
    Accounting Correlation Index)

SS MAC Address
48-bit MAC address that identifies SS

Service Flow identifier
32-bit service flow identifier that will identify service flows of an SS, which the accounting information is provided for

Accounting Record Number
Identifies accounting record within one session

Accounting Octets
The number of octets recorded at the SS for the given service flow during the session.

Accounting Packets
The number of packets recorded at the SS for the given service flow during the session.

Service Flow Information
Required QoS information of the service flow, which the accounting information is provided for. It includes traffic characteristics and a scheduling type such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency.

Accounting Correlation Index
Provides a unique correlation index for generated records. This field can contain the Account Session ID or the Account-Multi-Session ID that is typically used by the AAA server to consolidate the session records.

14.2.1.2.2.3 When generated

This primitive shall be generated by the BS in response to an M-ACM-REQ primitive.

14.2.1.2.2.4 Effect of receipt

The NCMS receives the primitive, it contains the requested information and it is assumed that the NCMS will use this information for accounting purposes.

14.2.1.2.3 M-ACM-IND

14.2.1.2.3.1 Function

This primitive is issued by a BS to inform the NCMS of an accounting event for MS Network Entry after Registration request/response (REG-REQ/RSP), or Deregistration command (DREG-CMD) of an MS, or DSA/DSC/DSD-REQ/RSP events.
14.2.1.2.3.2 Semantics of the service primitive

The parameters of the primitive are as follows:

M-ACM-IND

(  
  Event_Type: Accounting,
  Destination: NCMS,
  Attribute_List:
    SS MAC Address,
    Service Flow Identifier,
    Accounting Type
)

SS MAC Address
48-bit MAC address that identifies SS

Service Flow identifier
32-bit service flow identifier that will identify service flows of an SS, which the accounting information is provided for. This is valid only when accounting type is “service flow creation,” “service flow change,” or “service flow deletion.”

Accounting Type
This identifies the type of accounting events; value range:
  Registration,
  Service Flow Creation,
  Service Flow Change,
  Service Flow Deletion,
  De-registration

14.2.1.2.3.3 When generated

This primitive is generated at a BS when any accounting events have occurred.

14.2.1.2.3.4 Effect of receipt

NCMS will generate M-ACM-REQ primitive to retrieve the accounting records from BS.

14.2.2 Security management

14.2.2.1 EAP-based authentication procedure

When an SS tries to initiate an EAP-based authentication or re-authentication procedure with a BS, an NCMS(SS) sends a C-SM_IND/EAP_Start primitive to the IEEE 802.16 entity (SS) and the IEEE 802.16 entity (SS) sends a PKMv2 EAP_Start message. The BS informs the AAA Services entity in NCMS (i.e., the authenticator) by sending the C-SM-IND/EAP_Start primitive. If the SS receives EAP-Request/Identity messages, then it sends the EAP-Response/Identity message with SS MAC Address to the AAA Services entity. After the EAP-Response/Identity message, the EAP methods are negotiated between the SS and the AAA server and the EAP messages are exchanged several times. The EAP encapsulated messages are exchanged between the SS and the AAA Services entity. If the EAP authentication procedure is finished successfully and also yields an MSK (Master Session Key), the BS which does not know EAP protocols receives the AK and a key lifetime from the authenticator, which is part of the AAA Services entity, in the C-SM-IND/AK_Transfer primitive. The MSK is already shared between the AAA server and the SS through the EAP exchanges. The MSK is used by the SS and authenticator for derivation of the PMK (Pairwise Master Key) and optional EIK (EAP Integrity Key).
Figure 341 shows EAP-based authentication procedures between an IEEE 802.16 entity and the AAA and Security Services in NCMS as follows:

14.2.2.1.1 C-SM-IND

This primitive is used by an IEEE 802.16 entity or NCMS to notify security procedures. The Event_Type included in this primitive defines the type of security operation in Authentication and Re-authentication procedure to be performed. The possible Event_Types for this primitive are listed in the following table:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAP_Start</td>
<td>EAP Start</td>
</tr>
<tr>
<td>AK Transfer</td>
<td>AK Transfer notification</td>
</tr>
<tr>
<td>EAP_Transfer</td>
<td>Transfer EAP Payload</td>
</tr>
</tbody>
</table>

14.2.2.1.1.1 C-SM-IND (Event_Type = EAP_Start)

14.2.2.1.1.1 Function

This primitive informs an IEEE 802.16 entity (SS) or an NCMS(BS) that an SS is going to start an EAP-based authentication. The PKMv2 EAP_Start is sent by the SS to initiate either an initial EAP authentication or EAP re-authentication exchange.
14.2.2.1.1.2 Semantics of the service primitives

The parameters of the primitives are as follows:

**C-SM-IND**

```plaintext
( Event_Type: EAP_Start,
  Destination: NCMS, SS
  Attribute_List:
    SS MAC Address,
    BSID )
```

- **SS MAC Address**: 48-bit unique identifier used for user identification between BS and NCMS
- **BSID**: 48-bit unique identifier used for BS

14.2.2.1.1.3 When generated

- NCMS(SS) to IEEE 802.16 entity (SS): This primitive is issued by an NCMS(SS) when an SS wants to initiate EAP-based authentication procedure.
- IEEE 802.16 entity (BS) to NCMS(BS): This primitive is issued by an IEEE 802.16 entity (BS) in EAP procedure when an IEEE 802.16 entity (BS) receives a PKM-REQ message with PKMv2 EAP_Start.

14.2.2.1.1.4 Effect of receipt

- NCMS(SS) to IEEE 802.16 entity (SS): When received by the IEEE 802.16 entity (SS), the IEEE 802.16 entity (SS) forwards a PKM-REQ message with PKMv2 EAP_Start.
- IEEE 802.16 entity (BS) to NCMS(BS): When received by the NCMS(BS), the NCMS(BS) requests an AAA Authenticator to initiate an EAP-based authentication.

14.2.2.1.1.2 Reserved

14.2.2.1.1.3 C-SM-IND (Event_Type = AK Transfer)

14.2.2.1.1.3.1 Function

An NCMS derives the key from the EAP payloads, yields PMK from the MSK, then yields AK from the PMK, and informs the IEEE 802.16 entity of the AK when the EAP exchanges are successfully completed by the AAA service entities.

14.2.2.1.1.3.2 Semantics of the service primitives

The parameters of the primitives are as follows:

**C-SM-IND**

```plaintext
( Event_Type: AK_Transfer,
  Destination: BS, SS
  Attribute_List:
    SS MAC Address,
    AK,
    AK Lifetime,
)```
AK Sequence Number,
AKID
)

SS MAC Address
48-bit unique identifier used for user identification between BS and NCMS

AK
AK is the product of PMK after successful EAP exchanges. It is used for protecting air interface messages and KEK.

AK Lifetime
AK Lifetime shall be set in accordance with PMK and MSK Lifetime. PMK and MSK Lifetime shall be transferred from the EAP method and could also be configured by the AAA Services.

AK Sequence Number
AK Sequence Number shall be derived from PMK Sequence Number.

AKID
It should be derived according to 7.2.2.4.1.

14.2.2.1.1.3.3 When generated
— NCMS(SS) to IEEE 802.16 entity (SS): This primitive is issued by the NCMS(SS) when the EAP procedure is finished.
— IEEE 802.16 entity (BS) to NCMS(BS): This primitive is issued by the NCMS(BS) (the AAA Services entity, i.e., Authenticator) when the EAP procedure is finished.

14.2.2.1.1.3.4 Effect of receipt
— NCMS(SS) to IEEE 802.16 entity (SS): The IEEE 802.16 entity (SS) could derive other AK context (HMAC/CMAC_KEY_U, HMAC/CMAC_KEY_D, HMAC/CMAC_PN_U, and HMAC/CMAC_PN_D, KEK).
— IEEE 802.16 entity (BS) to NCMS(BS): The IEEE 802.16 entity (BS) could derive other AK context (HMAC/CMAC_KEY_U, HMAC/CMAC_KEY_D, HMAC/CMAC_PN_U, and HMAC/CMAC_PN_D, KEK).

14.2.2.1.1.4 C-SM-IND (Event_Type = EAP_Transfer)

14.2.2.1.1.4.1 Function
After the C-SM-IND/EAP_Start primitive, EAP payloads are exchanged between an SS and an AAA server. The EAP payloads are encapsulated in the C-SM-IND/EAP_Transfer because it is not interpreted in the MAC. C-SM-IND/EAP_Transfer is used between the NCMS and the IEEE 802.16 entity.

14.2.2.1.1.4.2 Semantics of the service primitives
The parameters of the primitives are as follows:

C-SM-IND
(  
   Event_Type: EAP TRANSFER,
   Destination: SS, BS or NCMS,
   Attribute_list:
       MS MAC Address,
       EAP Payload
)

SS MAC Address
48-bit unique identifier used for user identification between BS and NCMS.

**EAP Payload**
The EAP authentication data.

### 14.2.2.1.1.4.3 When generated

- NCMS(SS) to IEEE 802.16 entity (SS): This primitive can be issued by a NCMS(SS) in an EAP procedure to transfer an EAP Message to an IEEE 802.16 entity (SS).
- IEEE 802.16 entity (BS) to NCMS(BS): This primitive can be issued by an IEEE 802.16 entity (BS) in an EAP procedure to transfer an EAP Message included in PKMv2 PKM-REQ message.
- NCMS(BS) to IEEE 802.16 entity (BS): This primitive can be issued by a NCMS(BS) in EAP procedure to transfer an EAP Message to an IEEE 802.16 entity (BS).
- IEEE 802.16 entity (SS) to NCMS(SS): This primitive can be issued by an IEEE 802.16 entity (SS) in EAP procedure to transfer an EAP Message included in PKMv2 PKM-RSP message.

### 14.2.2.1.1.4.4 Effect of receipt

- NCMS(SS) to IEEE 802.16 entity (SS): When received by an IEEE 802.16 entity (SS), the SS forwards EAP payload to the BS in a PKM-REQ message.
- IEEE 802.16 entity (BS) to NCMS(BS): When received by NCMS(BS), the NCMS(BS) generates a next EAP payload or can derive PMK and optional EIK from the MSK, then AK context from PMK after a successful authentication procedure.
- NCMS(BS) to IEEE 802.16 entity (BS): When received by an IEEE 802.16 entity (BS), the BS forwards EAP payload to the SS in an PKM-RSP message.
- IEEE 802.16 entity (SS) to NCMS(SS): When received by NCMS(SS), the NCMS(SS) generates a next EAP payload or can derive PMK and optional EIK from the MSK, then AK context from PMK after a successful authentication procedure.

### 14.2.2.1.1.5 Reserved

### 14.2.2.2 RSA-based authentication procedure

When an SS tries to initiate an RSA-based authentication or re-authentication procedure with a BS, it sends PKM-REQ messages with Auth Info, Auth Request or PKMv2 RSA-Request message type. When an NCMS(SS) sends a C-SM-REQ/Certificate_Information primitive to an IEEE 802.16 entity (SS), the SS sends a PKM-REQ message with Auth Info message type, which includes a CA’s certificate to the IEEE 802.16 entity (BS), and the IEEE 802.16 entity (BS) informs the NCMS(BS) by a C-SM-REQ/Certificate_Information primitive. The NCMS(BS) verifies the CA’s certificate if it has no information about the CA and keeps the certificate.

When an NCMS(SS) sends a C-SM-REQ/Certificate_Verification primitive to the IEEE 802.16 entity(SS) to authenticate the SS and the IEEE 802.16 entity (SS) sends a PKM-REQ message with Auth Request or PKMv2 RSA-Request message type, the IEEE 802.16 entity (BS) notifies the NCMS(BS) by a C-SM-REQ/Certificate_Verification primitive. The NCMS(BS) verifies the SS’s certificate through asking to a CA and an OCSP (Online Certificate Status Protocol) server. The NCMS returns the result of verification to the IEEE 802.16 entity (BS) whether the SS is authenticated or not as a C-SM-RSP/Certificate_Verification primitive. The IEEE 802.16 entity (BS) sends the result of authentication and security information to the IEEE 802.16 entity (SS) including security key information and the IEEE 802.16 entity (SS) returns the result as a C-SM-RSP/Certificate_Verification primitive.to the NCMS(SS).

Figure 342 shows an RSA-based authentication procedure between an IEEE 802.16 entity and an NCMS on the MS side and the BS side as follows:
14.2.2.2.1 C-SM-IND

This primitive is used by an NCMS(SS) or an IEEE 802.16 entity (BS) to notify security procedures. The Event_Type included in this primitive defines the type of security operation in Authentication and Re-authentication procedure to be performed. The possible Event_ Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate Information</td>
<td>Certificate Information request</td>
</tr>
</tbody>
</table>

14.2.2.2.1.1 Function

This primitive informs the IEEE 802.16 entity (SS) of the certificate of the CA that issued the SS's certificate. In addition, this primitive informs the NCMS(BS) of the certificate of the CA that issued the SS's certificate.

14.2.2.2.1.2 Semantics of the service primitives

The parameters of the primitives are as follows:

```
C-SM-IND
(
  Event_Type: Certificate Information,
  Destination: NCMS, SS,
  Attribute_List:
    SS MAC Address,
    Certificate
)
```
14.2.2.2.2 C-SM-REQ

This primitive is used by an NCMS(SS) or an IEEE 802.16 entity (BS) to trigger security procedure or request security information. The Action_Type included in this primitive defines the type of security operation in Authentication and Re-authentication procedure to be performed. The possible Action_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate Verification</td>
<td>Certificate Verification Request</td>
</tr>
</tbody>
</table>

14.2.2.2.2.1 Function

This primitive is used by an NCMS(SS) or an IEEE 802.16 entity (BS) to inform an IEEE 802.16 entity (SS) or the NCMS(BS) of an SS’s certificate to authenticate the SS.

14.2.2.2.2.2 Semantics of the service primitives

The parameters of the primitive are as follows:

C-SM-REQ
(    
    Operation_Type: Action, 
    Action_Type: Certificate Verification, 
    Destination: BS, NCMS, 
    Attribute_List: 
        SS MAC Address, 
        Certificate 
)
SS MAC Address
48-bit unique identifier used for user identification between a BS and the NCMS

Certificate
SS's certificate that is issued by a trusted CA

14.2.2.2.2.3 When generated

— NCMS(SS) to IEEE 802.16 entity (SS): This primitive is issued by an NCMS(SS) when an SS requests a BS for authentication to access the network.
— IEEE 802.16 entity (BS) to NCMS(BS): This primitive can be issued by IEEE 802.16 entity(BS) in RSA procedure to transfer a SS’s certificate included in a PKM-REQ message.

14.2.2.2.4 Effect of receipt

— NCMS(SS) to IEEE 802.16 entity (SS): When received by an IEEE 802.16 entity (SS), the SS forwards SS’s certification in a PKM-REQ message to the BS.
— IEEE 802.16 entity (BS) to NCMS(BS): The NCMS(BS) verifies the validity of the SS’s certificate.

14.2.2.2.3 C-SM-RSP

This primitive is used by an NCMS(BS) or an IEEE 802.16 entity (SS) to respond to the security information request. The Action_Type included in this primitive defines the type of security operation in Authentication and Reauthentication procedure to be performed. The possible Action_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate Verification</td>
<td>Certificate Verification Response</td>
</tr>
</tbody>
</table>

14.2.2.2.3.1 Function

This primitive informs the IEEE 802.16 entity (BS) or the NCMS(SS) of the result of the SS's authentication by the NCMS entity.

14.2.2.2.3.2 Semantics of the service primitives

The parameters of the primitives are as follows:

C-SM-RSP
( Operation_Type: Action,
  Action_Type: Certificate_Verification,
  Destination: BS, NCMS,
  Attribute_List:
    SS MAC Address,
    Result
)

SS MAC Address
48-bit unique identifier used for user identification between a BS and the NCMS

Result
Result of authentication such as valid, forged or revoked
14.2.2.3.3 When generated

— NCMS(BS) to IEEE 802.16 entity (BS): This primitive informs the IEEE 802.16 entity (BS) about
the authentication result.
— IEEE 802.16 entity (SS) to NCMS(SS): This primitive informs the NCMS(SS) about the
authentication result.

14.2.2.3.4 Effect of receipt

— NCMS(BS) to IEEE 802.16 entity (BS): The IEEE 802.16 entity (BS) transmits a PKM-RSP
message to the IEEE 802.16 entity (SS). If the result is successful, a pre-Primary AK is included in it.
— IEEE 802.16 entity (SS) to NCMS (SS): The NCMS (SS) receives this message and the authentication
result.

14.2.2.3 Security for handoffs (EAP only)

In the handover procedure, if an MS indicates to the serving BS that it is moving to a target BS, the serving
BS may initiate a context transfer procedure to the target BS.

Figure 343 shows the context transfer primitives initiated by a serving BS between a BS and the NCMS
entity.

![Figure 343—Context transfer primitives initiated by a serving BS](image)

If an MS tries to process the network re-entry to a target BS, but the target BS has no MS information, then
the target BS may request the MS information from the NCMS’s Mobility Management Services or Security
Services and the NCMS should respond. Figure 344 shows the context transfer procedure initiated by a
target BS.
14.2.2.3.1 Service primitives

14.2.2.3.1.1 C-SM-REQ

This primitive is used by an IEEE 802.16 entity or NCMS to indicate the transfer of the security context. The Action_Type included in this primitive defines the type of security operation handover procedure to be performed. The possible Action_ Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context Transfer</td>
<td>Context Transfer Indication</td>
</tr>
</tbody>
</table>

14.2.2.3.1.1.1 Function

This primitive is issued by the serving BS or the NCMS entity in order to give the target BS the required security context information of the MS. It is transmitted to the pruned down target BS after the handover procedure.

14.2.2.3.1.1.2 Semantics of the service primitives

The parameters of the primitives are as follows:

C-SM-REQ

( Operation_Type: Action,
  Action_Type: Context_Transfer,
  Destination: NCMS or BS,
  MS MAC Address,
Attribute List:
   - Serving BSID,
   - Target BSID,
   - Security Information

**MS MAC Address**
48-bit unique identifier used for user identification between BS and NCMS

**Serving BSID**
Base station unique identifier of the serving BS (same as in the DL-MAP)

**Target BSID**
Base station unique identifier of the target BS (same as in the DL-MAP)

**Security Information**
The information negotiated during PKM procedure. It is present when the information could be provided. AK and AK sequence number transmitted by NCMS, TEK, TEK key lifetime, TEK sequence number, CBC Initialize Vector (the reuse of IV is TBD because of the security issue), SAID, GKEK, GKEK lifetime, GKEKKID, SA-type, SA service type, Cryptographic-Suite, and Authenticator ID

14.2.2.3.1.1.3 When generated

- IEEE 802.16 entity (BS) to NCMS: Context transfer initiated by a serving BS.
- NCMS to IEEE 802.16 entity (BS): Context transfer initiated by a target BS.

14.2.2.3.1.1.4 Effect of receipt

- IEEE 802.16 entity (BS) to NCMS: NCMS entity shall forward the MS information to the target BS or another NCMS entity using C-SM-RSP/Context Trans.
- NCMS to IEEE 802.16 entity (BS): BS responds with C-SM-RSP message.

14.2.2.3.1.2 C-SM-RSP

This primitive is used by an IEEE 802.16 entity or NCMS to respond to the C-SM-REQ. The Action_Type included in this primitive defines the type of security operation handover procedure to be performed. The possible Action_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context Transfer</td>
<td>Context Transfer Confirmation</td>
</tr>
</tbody>
</table>

14.2.2.3.1.2.1 Function

This primitive is issued by the target BS or the NCMS in order to respond to the C-SM-REQ/Context_Transfer.

14.2.2.3.1.2.2 Semantics of the service primitives

The parameters of the primitives are as follows:

C-SM-RSP

  (Operation_Type: Action,
Action_Type: Context_Transfer,
Destination: NCMS or BS,
Attribute_List:
    MS MAC Address
    Serving BSID,
    Target BSID,
    Result Code,
    Security Information
)

MS MAC Address
48-bit unique identifier used for user identification between BS and NCMS.

Serving BSID
Base station unique identifier of the serving BS (same as in the DL-MAP).

Target BSID
Base station unique identifier of the target BS (same as in the DL-MAP).

Result Code
The result of context transfer procedure.

Security Information
The information negotiated during PKM procedure. It is present when the information could be provided. AK and AK sequence number transmitted by NCMS, TEK, TEK key lifetime, TEK sequence number, CBC Initialize Vector (the reuse of IV is TBD because of the security issue), SAID, GKEK, GKEK lifetime, GKEKKID, SA-type, SA service type, Cryptographic-Suite, and Authenticator ID.

14.2.2.3.1.2.3 When generated

— IEEE 802.16 entity (BS) to NCMS: BS sends this primitive when the C-SM-REQ/Context_Transfer is successfully processed.
— NCMS to IEEE 802.16 entity (BS): NCMS sends this primitive when the C-SM-REQ/Context_Transfer is successfully processed.

14.2.2.3.1.2.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: BS informs the result of context transfer for the handover.
— NCMS to IEEE 802.16 entity (BS): NCMS informs the result of context transfer for the handover.

14.2.3 IP management with Secondary Management Connection

These primitives are provided when the IP connection is managed by the secondary management connection. It is available for both IPv4 and IPv6. IP management uses the Mobility Management Services in the NCMS.
14.2.3.1 M-SMC-IND

This primitive is used by an IEEE 802.16 entity or the NCMS to transfer payload information that may include IP address, signaling and information. It also can be used by the NCMS to notify the BS of an SS IP address status change and its new address. The Event_Type included in this primitive defines the information included in this primitive. The possible Event_TYPES for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMC-PAYLOAD</td>
<td>Forward SMC payload.</td>
</tr>
<tr>
<td>IP_ALLOCATION</td>
<td>NCMS notify the BS of an SS' IP address status change</td>
</tr>
</tbody>
</table>

14.2.3.1.1 M-SMC-IND (Event_Type = SMC-PAYLOAD)

14.2.3.1.1.1 Function

SMC payload is sent from NCMS to IEEE 802.16 entity.

14.2.3.1.1.2 Semantics of the service primitives

The parameters of the primitives are as follows:

M-SMC-IND

```c
    (Event_Type: SMC-PAYLOAD,
     Destination: SS, BS, or NCMS,
     Attribute_list:
```
SS MAC Address
   48-bit unique identifier used for the IEEE 802.16 entity identification.

SMC Payload
   Contains the SMC payload

14.2.3.1.3 When generated

   — IEEE 802.16 entity to NCMS: This primitive is generated when the IEEE 802.16 entity sends to the NCMS traffic received over the secondary management connection.
   — NCMS to IEEE 802.16 entity: This primitive is used when the NCMS wants to send SMC traffic over the air.

14.2.3.1.4 Effect of receipt

   — IEEE 802.16 entity to NCMS: On receipt of this primitive from the M-SAP, the NCMS examines the payload. If it contains IP address signaling, the NCMS will engage the proper signaling agent (DHCP or MIP).
   — NCMS to IEEE 802.16 entity: On receipt of this primitive the IEEE 802.16 entity transfers the SMC payload over the air.

14.2.3.1.2 M-SMC-IND(Event_Type = IP_ALLOCATION)

14.2.3.1.2.1 Function

When the IP address for an SS is changed, the NCMS in the BS may notify the BS of the new status of the IP SS address. If the status value is NEW, the NCMS sends the new allocated IP address. This primitive is only sent from the NCMS to the BS.

14.2.3.1.2.2 Semantics of the service primitives

The parameters of the primitives are as follows:

M-SMC-IND
   (Event_Type: IP_ALLOCATION, Destination: BS, Attribute_list:
   SS MAC Address, Status, IP Address)

SS MAC Address
   48-bit unique identifier used for user identification between BS and NCMS.

Status
   The status of the IP address of an SS. The value may be NEW, REMAIN, RELEASE.

IP Address
   If the Status value is NEW, this parameter should be the new allocated address of the SS.
14.2.3.1.2.3 When generated

This primitive is issued by the NCMS when the IP address of the SS has changed.

14.2.3.1.2.4 Effect of receipt

The BS learns about the status and the new IP address of the SS.

14.2.4 Subscriber mode management

14.2.4.1 Managing device states

In Normal Operation, an MS transmits and receives packets to/from a BS. Currently, three subscriber modes are defined, i.e., Normal, Sleep and Idle Modes. Sleep Mode is intended to minimize an MS power usage and decrease usage of serving BS air interface resources by pre-negotiated periods of absence from the serving BS air interface. Idle Mode allows an MS to become periodically available for DL broadcast traffic without registration at a specific BS as the MS traverses an air link environment populated by multiple BSs, and thus, allows the MS to conserve power and operational resources.

Figure 346—Subscriber mode transition diagram at MS and BS

Sleep Mode operation is defined between an MS and a BS only, and the NCMS does not need to manage the subscriber’s Sleep Mode. Thus, both an MS and a BS manage the Normal Operation, Sleep Mode, and Idle Mode of the subscriber. On the other hand, the Paging and Idle Mode Management Services in the NCMS
manages Idle Mode operation, and the transition from Normal Operation and Idle Mode. Subscriber Mode transitions at an MS, BS and the NCMS are illustrated in Figure 346 and Figure 347.

The parenthesis in Figure 346 and Figure 347 consists of condition and action for state transition, \((condition, action)\). For example, \((C\text{-IMM-REQ}, C\text{-IMM-ACK})\) means that if an NCMS receives C-IMM-REQ, it sends C-IMM-ACK. If there is no output primitive action, ‘/’ is used. For example, \((C\text{-IMM-RSP}, /)\) means that if the NCMS receives C-IMM-RSP, it does not perform any action.

Figure 346 shows Subscriber Mode transition diagram at both an MS and a BS. Subscriber Mode at both an MS and a BS changes from Normal Operation to Idle Mode when the MS issues an MS De-registration Request (DREG-REQ) message with De-Registration_Request_Code=0x01 or the BS issues an De-register Command (DREG-CMD) message with Action Code = 0x05. Then, the MS stays at Idle Mode and updates its location when the paging group changes. The Subscriber Mode returns back to Normal Operation from Idle Mode after completing Network re-entry. Transition from Normal Operation to Sleep Mode is performed after an MS successfully exchanges Sleep Request (MOB_SLP-REQ) and Sleep Response (MOB_SLP-RSP) messages with a BS. If there is any DL traffic toward an MS from a BS, MOB_TRF-IND is broadcast to the MS from the BS and the Subscriber Mode of the MS and the BS changes from Sleep Mode to Normal Operation. If there is any UL traffic from an MS, Bandwidth Request (BW Request) is sent to the serving BS from the MS and the Subscriber Mode of the MS and the BS changes from Sleep Mode to Normal Operation, too.

Figure 347 shows Subscriber Mode transition diagram at the NCMS with service primitives related with the Subscriber Mode transition. Subscriber Mode transition from Normal Operation to Idle Mode is performed by exchanging C-IMM-REQ and C-IMM-RSP between an IEEE 802.16 entity and the NCMS after successful DREG-REQ message from the MS with De-Registration_Request_Code=0x01 or DREG-CMD message from the BS with Action Code = 0x05, where C-IMM-REQ and C-IMM-RSP are defined in 14.2.4.2.1 and 14.2.4.2.2, respectively. Subscriber Mode transition from Idle Mode to Normal Operation is initiated after exchanging C-IMM-RSP and C-IMM-ACK between an IEEE 802.16 entity and the NCMS, where C-IMM-RSP and C-IMM-ACK are defined in 14.2.4.2.2 and 14.2.4.2.3, respectively.

![Figure 347—Subscriber mode transition diagram at NCMS (on BS and MS side)](image-url)
14.2.4.2 Idle mode management primitives

Figure 348—Idle mode initiation (by NCMS on the MS side)

Figure 349—Idle mode initiation (initiated by the NCMS on the BS side)
Figure 350—Paging Announce

Figure 351—Network re-entry from idle mode primitives
14.2.4.2.1 C-IMM-REQ

This primitive is used by an IEEE 802.16 entity or NCMS to trigger an idle mode management procedure. The Action Type included in this primitive defines the type of idle mode management procedure to be performed. The possible Action Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle_Mode_Initiation</td>
<td>Idle Mode Initiation Request</td>
</tr>
<tr>
<td>Network_Re-Entry_from_Idle_Mode</td>
<td>Network Re-Entry from Idle Mode Request</td>
</tr>
</tbody>
</table>

14.2.4.2.1.1 C-IMM-REQ (Action_Type = Idle_Mode_Initiation)

14.2.4.2.1.1 Function

This primitive is issued by an NCMS (MS or BS) to initiate idle mode.

14.2.4.2.1.2 Semantics of the service primitive

The parameters of the primitive are as follows:

C-IMM-REQ

( Operation_Type: Action,
  Action_Type: Idle_Mode_Initiation,
  Destination: NCMS, BS, MS,
  Attribute_List:
    MS MAC Address,
    Paging_Information,
    Paging Controller ID,
    Security Information,
    Idle Mode Retain Information,
    MAC Hash Skip Threshold,
    Service Flow parameters,
    Service and operational information
)

MS MAC Address
48-bit MAC Address that identifies MS during Idle Mode

Paging_Information
Paging Group ID, Paging Cycle, Paging Offset

Paging Controller ID
A logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administrating paging activity for the MS while in Idle Mode. The Paging Controller ID shall be set to the BSID when a BS is acting as the Paging Controller.

Security Information
AK Context, security association info, authenticator ID, etc.

Idle Mode Retain Information
MS request for Paging Controller retention of MS service and operational information to expedite future Network Re-entry from Idle Mode. (See 6.3.2.3.42.)

MAC Hash Skip Threshold
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS individual notification for an MS, including MS MAC Address Hash of an MS for which Action Code is 0b00, ‘No Action Required.’

**Service Flow parameters**
Parameters for the existing Service Flow without actually activating it to carry traffic at MS Idle Mode Initiation, e.g., Paging Preference.

**Service and operational information**
MS service and operational information associated with MAC state machines, CS classifier information, etc.

### 14.2.4.2.1.1.3 When generated

- **NCMS(MS) to IEEE 802.16 entity (MS):** This primitive is generated by an NCMS(MS) when the NCMS(MS) decides on idle mode initiation.
- **IEEE 802.16 entity (BS) to NCMS(BS):** This primitive is generated by an IEEE 802.16 entity (BS) when the IEEE 802.16 entity (BS) receives MAC messages for initiation of idle mode (DREG-REQ with Deregistration_Request_Code=0x01, “request for MS De-Registration from serving BS and initiation of MS Idle Mode”)
- **NCMS(BS) to IEEE 802.16 entity (BS):** This primitive is generated by an NCMS(BS) when the NCMS(BS) decides on idle mode initiation.
- **IEEE 802.16 entity (MS) to NCMS(MS):** This primitive is generated by an IEEE 802.16 entity (MS) when the IEEE 802.16 entity (MS) receives MAC messages for initiation of idle mode (DREG-CMD with Action Code = 0x05).

### 14.2.4.2.1.1.4 Effect of receipt

- **NCMS(MS) to IEEE 802.16 entity (MS):** When the IEEE 802.16 entity (MS) receives the C-IMM-REQ, the MS shall transmit DREG-REQ with Deregistration_Request_Code=0x01.
- **IEEE 802.16 entity (BS) to NCMS(BS):** The NCMS shall respond to this primitive with C-IMM-RSP(Idle_Mode_Initiation) and performs idle mode initiation procedure.
- **NCMS(BS) to IEEE 802.16 entity (BS):** When the IEEE 802.16 entity (BS) receives the C-IMM-REQ, the BS shall transmits DREG-CMD with Action Code = 0x05.
- **IEEE 802.16 entity (MS) to NCMS(MS):** The NCMS responds to this primitive with C-IMM-RSP(Idle_Mode_Initiation) and performs idle mode initiation procedure.

### 14.2.4.2.1.2 C-IMM-REQ (Action_Type = Network_Re-Entry_from_Idle_Mode)

#### 14.2.4.2.1.2.1 Function

This primitive is issued by an NCMS of an MS to inform the IEEE 802.16 entity of the MS that the MS is attempting to re-enter the network. This primitive is also issued by a BS to inform the Paging and Idle Mode Services entity in the NCMS(BS) that the specified MS is attempting to re-enter network in response to paging.

#### 14.2.4.2.1.2.2 Semantics of the service primitive

The parameters of the primitive are as follows:

```
C-IMM-REQ
    (Operation_Type: Action,
     Action_Type: Network_Re-Entry_from_Idle_Mode,
```

---

Copyright © 2009 IEEE. All rights reserved. 1811
MS MAC Address
48-bit MAC Address that identifies MS during Idle Mode

Paging Information
Paging Group ID, Paging Cycle, and Paging Offset parameters used by MS in Idle Mode.

Paging Controller ID
A logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administrating paging activity for the MS while in Idle Mode. The Paging Controller ID shall be set to the BSID when a BS is acting as the Paging Controller.

BSID
A network identifier of the BS at which the MS is attempting to re-enter network

14.2.4.2.1.2.3 When generated

— NCMS(MS) to IEEE 802.16 entity (MS): This primitive is generated by an NCMS(MS) when the NCMS(MS) performs network re-entry.

— IEEE 802.16 entity (BS) to NCMS(BS): This primitive is generated by an IEEE 802.16 entity (BS) when it receives a RNG-REQ message including Ranging Purpose Indication with setting bit 0 to 1 in combination with Paging Controller ID.

14.2.4.2.1.2.4 Effect of receipt

— NCMS(MS) to IEEE 802.16 entity (MS): If an IEEE 802.16 entity (MS) receives C-IMM-REQ(Network_Re-Entry_from_Idle_Mode), it shall generate a RNG-REQ to a BS.

— IEEE 802.16 entity (BS) to NCMS(BS): If an NCMS(BS) receives C-IMM-REQ(Network_Re-Entry_from_Idle_Mode), it shall respond to the request with the C-IMM-RSP (Network_Re-Entry_from_Idle_Mode) primitive.

14.2.4.2.2 C-IMM-RSP

The possible Action_Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle_Mode_Initiation</td>
<td>Idle Mode Initiation Response</td>
</tr>
<tr>
<td>Network_Re-Entry_from_Idle_Mode</td>
<td>Idle Re-Entry Response</td>
</tr>
</tbody>
</table>
14.2.4.2.2.1 C-IMM-RSP (Action_Type = Idle_Mode_Initiation)

14.2.4.2.2.1.1 Function

This primitive is issued by the Paging and Idle Mode Management entity in the NCMS in response to the C-IMM-REQ(Idle_Mode_Initiation) primitive.

14.2.4.2.2.1.2 Semantics of the service primitive

The parameters of the primitive are as follows:

```
C-IMM-RSP
  (  
    Operation_Type: Action,  
    Action_Type: Idle_Mode_Initiation,  
    Destination: NCMS, BS, MS,  
    Attribute_List:
      Action code,  
      MS MAC Address,  
      Paging Information,  
      Paging Controller ID,  
      Idle Mode Retain Information,  
      MAC Hash Skip Threshold,  
      REQ-duration
  )
```

**Action code**
Indicates the value of Action code to be included in DREQ-CMD message. (See Table 55.)

**MS MAC Address**
48-bit MAC Address that identifies MS during Idle Mode

**Paging Information**
Paging Group ID, Paging Cycle, and Paging Offset parameters followed by MS in Idle Mode.

**Paging Controller ID**
A logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administrating paging activity for the MS while in Idle Mode. The Paging Controller ID shall be set to the BSID when a BS is acting as the Paging Controller.

**Idle Mode Retain Information**
MS request for Paging Controller retention of MS service and operational information to expedite future Network Re-entry from Idle Mode. (See 6.3.2.3.42.)

**MAC Hash Skip Threshold**
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS individual notification for an MS, including MS MAC Address Hash of an MS for which Action Code is 0b00, 'No Action Required'.

**REQ-duration**
Waiting value for the DREG-REQ message re-transmission (measured in frames).

14.2.4.2.2.1.3 When generated

- NCMS(BS) to IEEE 802.16 entity (BS): This primitive is generated by the NCMS(BS) to request a IEEE 802.16 entity (BS) to issue a DREG-CMD message after receiving C-IMM-REQ(Idle_Mode_Initiation).
- IEEE 802.16 entity (MS) to NCMS(MS): This primitive is generated by an IEEE 802.16 entity (MS) to inform about the result of idle mode initiation.
— NCMS(MS) to IEEE 802.16 entity (MS): This primitive is generated by the NCMS(MS) to request a IEEE 802.16 entity (MS) to issue a DREG-REQ message after receiving C-IMM-REQ(Idle_Mode_Initiation).
— IEEE 802.16 entity (BS) to NCMS(BS): This primitive is generated by an IEEE 802.16 entity (BS) to inform result of idle mode initiation.

14.2.4.2.2.1.4 Effect of receipt
— NCMS(BS) to IEEE 802.16 entity (BS): When the IEEE 802.16 entity(BS) receives C-IMM-RSP(Idle_Mode_Initiation), the BS transmits DREG-CMD message with setting each field in accordance with the information elements in this primitive.
— IEEE 802.16 entity (MS) to NCMS(MS): The NCMS(MS) completes idle mode initiation.
— NCMS(MS) to IEEE 802.16 entity (MS): When the IEEE 802.16 entity(MS) receives C-IMM-RSP(Idle_Mode_Initiation), the MS transmits DREG-REQ message with setting each field in accordance with the information elements in this primitive.
— IEEE 802.16 entity (BS) to NCMS(BS): The NCMS(MS) completes idle mode initiation.

14.2.4.2.2 C-IMM-RSP (Action_Type = Network_Re-Entry_from_Idle_Mode)

14.2.4.2.2.1 Function
This primitive is issued by the Paging and Idle Mode Management entity to confirm the MS Network Re-entry from Idle Mode and provide the BS, at which the MS is attempting to re-enter the network, with service and operational information.

14.2.4.2.2.2 Semantics of the service primitive
The parameters of the primitive are as follows:

\[
\text{C-IMM-RSP} \\
\text{(Operation_Type: Action, Action_Type: Network_Re-Entry_from_Idle_Mode, Destination: BS, NCMS, Attribute_List: MS MAC Address, Security Information, Service and operational information, \ldots)}
\]

MS MAC Address
48-bit MAC Address that identifies MS during Idle Mode

Security Information
AK Context, Security Association Info, Authenticator ID, etc.

Service and operational information
MS service and operational information associated with MAC state machines, CS classifier information, etc.

14.2.4.2.2.3 When generated
— NCMS(BS) to IEEE 802.16 entity (BS): This primitive is generated by the NCMS(BS) to respond to C-IMM-REQ(Network_Re-Entry_from_Idle_Mode).
IEEE 802.16 entity (MS) to NCMS(MS): This primitive is generated by an IEEE 802.16 entity (MS) to inform about the result of network re-entry.

### 14.2.4.2.2.2.4 Effect of receipt

- NCMS(BS) to IEEE 802.16 entity (BS): When the IEEE 802.16 entity (BS) receives C-IMM-RSP(Network_Re-Entry_from_Idle_Mode), the BS shall transmit RNG-RSP message with setting each field in accordance with the information elements in this primitive. The BS acknowledges the receipt of this message by transmitting the C-IMM-ACK(Network_Re-Entry_from_Idle_Mode) message to the NCMS.
- IEEE 802.16 entity (MS) to NCMS(MS): The NCMS(MS) completes network re-entry.

### 14.2.4.2.3 C-IMM-ACK

The possible Action_Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network_Re-Entry_from_idle_Mode</td>
<td>Network Re-Entry from Idle Mode</td>
</tr>
</tbody>
</table>

#### 14.2.4.2.3.1 Function

This primitive is issued by a BS to inform the Paging and Idle Mode Management entity that an MS has re-entered network successfully.

#### 14.2.4.2.3.2 Semantics of the service primitive

The parameters of the primitives are as follows:

**C-IMM-ACK**

```plaintext
( Operation_Type: Action,
  Action_Type: Network_Re-Entry_from_idle_Mode,
  Destination: NCMS,
  Attribute_List:
    MS MAC Address,
    Paging Controller ID,
    BSID
)
```

**MS MAC Address**

48-bit MAC Address that identifies MS during Idle Mode.

**Paging Controller ID**

A logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administrating paging activity for the MS while in Idle Mode. The Paging Controller ID shall be set to the BSID when a BS is acting as the Paging Controller.

**BSID**

A network identifier of the BS at which the MS is attempting to re-enter network.
14.2.4.2.3.3 When generated

This primitive is generated by a BS when Network Re-entry process specified in 6.3.22.10 has been completed.

14.2.4.2.3.4 Effect of receipt

The buffered DL traffic is delivered to the serving BS and finally to MS.

14.2.4.2.4 C-IMM-IND

The possible Event_Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paging Announce</td>
<td>Paging Announce</td>
</tr>
</tbody>
</table>

14.2.4.2.4.1 Function

This primitive is issued by the Paging and Idle Mode Management entity in the NCMS to notify a BS to page an idle MS by transmitting a MOB_PAG-ADV message including the MS MAC Address Hash and relevant Action Code.

14.2.4.2.4.2 Semantics of the service primitive

The parameters of the primitives are as follows:

C-IMM-IND

(  
Event_Type: Paging Announce,
Destination: BS, NCMS,
Attribute_List:
  MS MAC Address,
  Paging Information,
  Action Code
)

MS MAC Address
48-bit MAC Address that identifies MS during Idle Mode

Paging Information
Paging Group ID, Paging Cycle, and Paging Offset parameters followed by MS in Idle Mode.

Action Code
Action required for MS in Idle Mode (e.g., Network Re-entry, ranging for location update, and so on)

14.2.4.2.4.3 When generated

— NCMS(BS) to IEEE 802.16 entity (BS): This primitive is generated by the Paging and Idle Mode Management entity to request a BS to transmit BS Broadcast Paging message.
— IEEE 802.16 entity (MS) to NCMS(MS): This primitive is generated by the IEEE 802.16 entity (MS) to inform about a paging announce.
14.2.4.2.4.4 Effect of receipt

— NCMS(BS) to IEEE 802.16 entity (BS): A BS receiving C-IMM-IND (Paging_Announce) shall transmit MOB_PAG-ADV message following the information provided by this primitive.
— IEEE 802.16 entity (MS) to NCMS(MS): The NCMS(MS) shall perform C-IMM-IND(Paging Announce).

14.2.4.3 Location update procedure

Location management of an MS is performed by mobility management service of the NCMS. An MS in idle mode performs Location Update in order to inform the NCMS of its current location information, i.e., paging group. This information is used to page the MS through the cells that belong to the paging group of the called MS when there is pending DL traffic toward the MS.

Location Update is performed if any of the Location Update conditions are met. There are currently four Location Update conditions defined: Zone Update, Timer Update, Power Down Update, and MAC Hash Skip Threshold Update. In Zone Update, the MS shall perform Location Update process when the MS detects a change in paging group by comparing the Paging Group identifier (PG_ID) stored in the MS with that of transmitted by the preferred BS in the DCD message or MOB_PAG-ADV broadcasting message. In Timer Update, MS shall periodically perform Location Update process prior to the expiration of the idle mode timer. In Power Down Update, the MS shall attempt to complete a Location Update once as part of its orderly power down procedure. In MAC Hash Skip Threshold update, the MS shall perform Location Update process when the MS MAC hash skip counter exceeds the MAC hash skip threshold.

All the above Location Updates are realized by Ranging request/response (RNG-REQ/RSP) message between an MS and a BS, and the C-IMM-REQ, C-IMM-RSP, C-IMM-IND service primitives are defined between an IEEE 802.16 entity and the NCMS to perform Location Update.

Figure 352 shows service primitives for Location Update between an IEEE 802.16 entity and the NCMS.
14.2.4.3.1 C-IMM-REQ

The possible Action_Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location Update</td>
<td>Location Update request</td>
</tr>
</tbody>
</table>

14.2.4.3.1.1 Function

This primitive is issued by a BS to inform the Mobility Management entity in the NCMS that an MS requests to initiate a Location Update procedure. This primitive is also used by an NCMS(MS) to trigger a location update procedure.

14.2.4.3.1.2 Semantics of the service primitive

The parameters of the primitives are as follows:

C-IMM-REQ

(  
  Operation_Type: Action,  
  Action_Type: Location Update,  
  Destination: MS, NCMS,  
  Attribute_List:  
    MS MAC Address,  
    BSID,
Paging Controller ID, Paging Group ID, MAC Hash Skip Threshold, Power Down Indicator, Security Context Indication

MS MAC Address
48-bit MAC address that identifies MS

BSID
Identifier of serving BS

Paging Controller ID
The Paging Controller ID is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in Idle Mode.

Paging Group ID
One or more logical affiliation groupings of BS

MAC Hash Skip Threshold
Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC address hash of an MS for which Action Code is 00, 'No Action Required'.

Power Down Indicator
Indicates the MS is currently attempting to perform Location Update due to power down.

Security Context Indication
Indicates whether the BS has the required security context information for secure location update.
0x00 = no security information available
0x01 = security information present

14.2.4.3.1.3 When generated
— NCMS(MS) to IEEE 802.16 entity (MS): This primitive is generated by an NCMS(MS) that wants to request location update by location update condition.
— IEEE 802.16 entity (BS) to NCMS(BS): This primitive is generated when an IEEE 802.16 entity(BS) receives RNG-REQ message with Paging Controller ID and Ranging Purpose Indication with bit 1 set to 1, MAC Hash Skip Threshold, Power Down Indicator, and Security Context Indication.

14.2.4.3.1.4 Effect of receipt
— NCMS(MS) to IEEE 802.16 entity (MS): Upon receiving this primitive, the IEEE 802.16 entity(MS) shall generate RNG-REQ message with the appropriate parameters setting.
— IEEE 802.16 entity (BS) to NCMS(BS): Upon receiving this primitive, the NCMS(BS) that is a management entity of Mobility Management Services shall respond with location update response.

14.2.4.3.2 C-IMM-RSP

The possible Action_Type for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location Update</td>
<td>Location Update response</td>
</tr>
</tbody>
</table>
14.2.4.3.2.1 Function

This primitive is issued by the NCMS(BS) to respond to Location Update request from the IEEE 802.16 entity. This primitive is also used by IEEE 802.16 entity (MS) to notify the NCMS(MS) that the location update procedure has been completed.

14.2.4.3.2.2 Semantics of the service primitive

The parameters of the primitives are as follows:

C-IMM-RSP

-C-IMM-RSP (Operation_Type: Action,
Action_Type: Location Update,
Destination: BS, NCMS,
Attribute_List:
  MS MAC Address,
  Location Update Result,
  Paging Information,
  Paging Controller ID,
  MAC Hash Skip Threshold,
  Power Down Response,
  Security Information)

MS MAC Address
-48-bit MAC address that identifies MS

Location Update Result
-Response to Location Update Request:
  0b00=Failure. The MS shall perform Network Re-entry from Idle Mode;
  0b01=Successful assignment of Paging Controller and Paging Information.
  0b10, 0b11: Reserved

Paging Information
-New Paging Information assigned to MS. Paging Information shall only be included if Location Update Response=0x01 and if Paging Information has changed. The Paging Information TLV defines the Paging Group ID, PAGING_CYCLE and PAGING OFFSET parameters to be used by the MS in IDLE mode. PAGING_CYCLE is the cycle in which the paging message is transmitted within the paging group. PAGING OFFSET determines the frame within the cycle in which the paging message is transmitted and it shall be smaller than PAGING CYCLE value. Paging Group ID specifies the paging group the MS is assigned to.

Paging Controller ID
-Paging Controller ID is a logical network identifier for the serving BS or other network entity retaining MS service and operational information and/or administering paging activity for the MS while in Idle Mode. Paging Controller ID shall only be included if Location Update Response=0x01 and if Paging Controller ID has changed.

MAC Hash Skip Threshold
-Maximum number of successive MOB_PAG-ADV messages that may be sent from a BS without individual notification for an MS, including MAC address hash of an MS for which Action Code for the MS is 00, ‘No Action Required.’ If BS does not include this TLV item in the RNG-RSP message, any BS may omit MAC Address Hash of the MS with Action Code 00, ‘No Action Required’ from any MOB_PAG-ADV message.

Power Down Response
-Indicates the MS’s Power Down Location Update result.
  0x00= Failure of Power Down Information Update.
0x01= Success of Power Down Information Update.

Security Information
The information that can be used by BS to implement authentication procedure. This information is optional and it is only included when Security Context Indication = 0x00 in C-IMM-REQ. (The BS does not have required security context information and needs to obtain it from the NCMS for secure location update.)

14.2.4.3.2.3 When generated

— NCMS(BS) to IEEE 802.16 entity (BS): This primitive is generated by the NCMS(BS) in order to request an IEEE 802.16 entity (BS) to issue a RNG-RSP message.
— IEEE 802.16 entity (MS) to NCMS(MS): This primitive is generated by an IEEE 802.16 entity(MS) to notify result of location response.

14.2.4.3.2.4 Effect of receipt

— NCMS(BS) to IEEE 802.16 entity (BS): The IEEE 802.16 entity (BS) receiving C-IMM-RSP(Location Update) shall transmit RNG-RSP message with the appropriate parameters settings.
— IEEE 802.16 entity (MS) to NCMS(MS): The NCMS(MS) receiving C-IMM-RSP(Location Update) shall complete the location update procedures.

14.2.4.3.3 C-IMM-IND

The possible Event Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location_Update_CMPLT</td>
<td>Notify the NCMS the location update procedure is completed</td>
</tr>
</tbody>
</table>

14.2.4.3.3.1 Function

This primitive is used by BS to notify that the location update procedure has been completed.

14.2.4.3.3.2 Semantics of the service primitive

The parameters of the primitives are as follows:

C-IMM-IND

(  
  Event_Type: Location_Update_CMPLT,
  Destination: NCMS,
  Attribute_List:
    MS MAC Address,
    BSID,
    Location Update Result
)

MS MAC Address
48-bit MAC address that identifies MS

BSID
Identifier of serving BS

Location Update Result
Notify the result of authentication interaction between BS and NCMS:

- 0x00 = Failure of Idle Mode Location Update. The MS shall perform Network Re-entry from Idle Mode
- 0x01 = Success of Idle Mode Location Update
- others: Reserved

14.2.4.3.3.3 When generated

This primitive is generated at a BS when it received C-IMM-RSP and finished the Location Update procedure. This primitive is in order to notify NCMS that the location update procedure has been completed.

14.2.4.3.3.4 Effect of receipt

The NCMS receives this message and get the information that the location update has been completed.

14.2.5 Handover management

14.2.5.1 Handover context for connections

Handover context for connections is the set of information that is shared between the serving BS and the target BS for re-establishment of the transport connections during HO. HO context consists of the following information:

- **General MS Information**
  - It is the information required to identify the MS. IP address and MAC address of the MS can be included in this information.

- **MS Capability Information**
  - It is the information about MS capabilities that need to be negotiated with the serving BS at the initial network entry.

- **Security Information**
  - It is the information negotiated during PKM procedure. If the MS and the target BS can derive the AK for them without the help of the serving BS, AK key may be excluded from this information.

- **Service Flow Information**
  - It is the information negotiated during DSx-related procedure.

- **MAC state Information**
  - It is the information used to maintain MAC state machine and to manage MAC PDU transmission.

For the re-establishment of connections at the Target BS during HO, the Serving BS shall provide the Target BS with the HO context through the Mobility Management Services entity in the NCMS using the HO primitives. If the target BS can not re-use some information in the HO context for restoring the former MAC state or re-establishing connections, the Mobility Management Services entity in NCMS may exclude the information from the shared HO context.

14.2.5.2 Handover control protocol procedures

The HO Control Primitives are a set of primitives for supporting HO procedure between IEEE 802.16 entity and NCMS. At the NCMS side, the existence of a Mobility Management Services entity is assumed, which processes the HO Control Primitives.
Figure 353 to Figure 361 show the HO Control Primitives.

![Figure 353—HO primitives flow between Serving BS and NCMS, BS initiated](image)

![Figure 354—HO primitives flow between serving BS and NCMS, NCMS initiated](image)
Figure 355—Primitive flow between NCMS at the MS and the MS when HO is initiated

Figure 356—HO primitives flow between MS and NCMS(MS side) for sending MOB_HO-IND
Figure 357—HO primitives flow between target BS and NCMS

Figure 358—HO primitives flow between IEEE 802.16 entity (BS) and NCMS for scanning
Figure 359—HO primitives flow between IEEE 802.16 entity (MS) and NCMS for Local Scanning Report

Figure 360—HO primitives flow between IEEE 802.16 entity (MS) and NCMS for Remote Scanning Report
14.2.5.2.1 C-HO-REQ

This primitive is used by an IEEE 802.16 entity or NCMS to trigger a handover procedure. The Action_Type included in this primitive defines the type of handover procedure to be performed. The possible Action Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HO-Serving</td>
<td>Handover procedure between current serving BS and NCMS.</td>
</tr>
<tr>
<td>HO-Target</td>
<td>Handover procedure between target BS and NCMS</td>
</tr>
<tr>
<td>HO-Scan</td>
<td>Neighbor BS scanning procedure.</td>
</tr>
<tr>
<td>HO-Mobile</td>
<td>Handover procedure between Mobile Station and NCMS.</td>
</tr>
</tbody>
</table>

The following subclauses define the primitive when its action type is set to a specific action.

14.2.5.2.1.1 C-HO-REQ(Action_Type = HO-Serving)

14.2.5.2.1.1 Function

This primitive is used by a serving BS or the Mobility Management Services entity in NCMS to start an HO procedure. The primitive is only used by IEEE 802.16 entity (BS) and NCMS at BS side.

14.2.5.2.1.2 Semantics of the service primitive

The following parameters are included in this primitive:

C-HO-REQ
(  
    Operation_Type: Action,  
    Action_Type: HO-Serving,  
    Destination: BS or NCMS,  
    Attribute_List:  
      Serving BSID,  
      MS MAC Address,  
      HO Type,  
      Mode,  
      Number of Recommended BSs,  
      Candidate target BS list,  
      Service flow information,  
      CS parameter information  
  )

**Serving BSID**  
Base station unique identifier (same number as that broadcasted on the DL-MAP message).

**MS MAC Address**  
48-bit unique identifier used by MS.

**HO Type**  
Indication of HO types; HO or MDHO/FBSS.

**Mode**  
Various modes in Anchor BS update or Active Set Update.

**Number of Recommended BSs**  
The number of BSs that are recommended by the MS or the serving BS as candidate target BSs. The information for each recommended BS is included in Candidate target BS list.

**Candidate target BS list**  
For BS generated primitive, this is the list of BSs that are recommended for a target BS. Additional HO quality information such as Service Level Prediction and RF Signal Information also can be included in this list. For NCMS generated primitive, this is the list of recommended target BSs by the Mobility Management Services entity. The BSs in the list may be the candidate target BSs for HO or an Anchor BS or Active BSs for MDHO/FBSS according to the value of HO type and Mode MS Access Information, Newly Allocation Information, and HO Quality Information can be included in this list.

**Service flow information**  
Information of all the service flows that have been established between the MS and the serving BS.

**CS parameter information**  
Approved IP filter rules of a service flow such as packet classification rule and IPv6 flow label.

### 14.2.5.2.1.1.3 When generated

- IEEE 802.16 entity (BS) to NCMS: This primitive is generated when the BS receives a MOB_MSHO-REQ message from the MS
- NCMS to IEEE 802.16 entity (BS): This primitive is used when the Mobility Management Services entity in NCMS instructs the BS to start handover procedure for a particular MS.

### 14.2.5.2.1.1.4 Effect of receipt

- IEEE 802.16 entity (BS) to NCMS: The Mobility Management Services entity in NCMS processes the information from this primitive. And it may trigger a handover procedure to one or more target BS.
- NCMS to IEEE 802.16 entity (BS): The BS processes the information from this primitive and shall send MOB_BSHO-REQ to the MS to start the handover procedure.
14.2.5.2.1.2 C-HO-REQ(Action_Type = HO-Target)

14.2.5.2.1.2.1 Function

This primitive is used by the Mobility Management Services entity in NCMS to inform target BSs of the pending HO. The primitive is only used by IEEE 802.16 entity (BS) and NCMS at BS side.

14.2.5.2.1.2.2 Semantics of the service primitive

It delivers the following parameters:

\[
\text{C-HO-REQ} \\
( \\
\quad \text{Operation_Type: Action,} \\
\quad \text{Action_Type: HO-Target,} \\
\quad \text{Destination: BS,} \\
\quad \text{Attribute_List:} \\
\quad \quad \text{Serving BSID,} \\
\quad \quad \text{MS MAC Address,} \\
\quad \quad \text{HO Type,} \\
\quad \quad \text{Mode,} \\
\quad \quad \text{Service flow information,} \\
\quad \quad \text{HO Quality Information,} \\
\quad \quad \text{CS parameter information} \\
\)
\]

**Serving BSID**
Base station unique identifier (Same number as that broadcasted on the DL-MAP message)

**MS MAC Address**
48-bit unique identifier used by MS

**HO Type**
Indication of HO types; HO or MDHO/FBSS

**Mode**
Various modes in Anchor BS update or Active Set Update

**Service flow Information**
Information of all the service flows that have been established between the MS and the serving BS

**HO Quality Information**
Information related with quality of HO procedure; Service Level Prediction, HO Optimization Flag, Arrival Time Difference, etc.

**CS parameter information**
Approved IP filter rules of a service flow such as packet classification rule and IPv6 flow label

14.2.5.2.1.2.3 When generated

When the Mobility Management Services entity in NCMS determines a target BS for a MS to handover to, the NCMS generates this primitive to start the handover process at the target BS.

14.2.5.2.1.2.4 Effect of receipt

The target BS prepares for the MS handover that may include pre-allocating resources for the MS and sends a response to the NCMS.
14.2.5.2.1.3 C-HO-REQ(Action_Type = HO-Scan)

14.2.5.2.1.3.1 Function

This primitive is issued by the Mobility Management Services entity in NCMS(BS) to request radio signal information of MSs. This primitive is also used by the Mobility Management Services entity in NCMS(SS/MS) to instruct the MS to request scanning interval, to start to scan or to report the scanning result to the NCMS(SS/MS) or to the Serving BS.

14.2.5.2.1.3.2 Semantics of the service primitive

The parameters of the primitive are as follow:

\[
\text{C-HO-REQ} \\
\text{(Operation_Type: Action, Action_Type: HO-Scan, Destination: BS or MS, Attribute_List: Number of MS, List of MS MAC Address, Scan Duration, Link Quality Threshold, Link Status Report Period, Report Target, List of Neighboring BS, List of Scanning Type)}
\]

14.2.5.2.1.3.3 When generated

— NCMS(BS) to IEEE 802.16 entity (BS): This primitive is generated when the Mobility Management Services entity in NCMS(Serving BS) decides that the MS should perform scanning and/or association of neighbor BSs and report the scanning result to the NCMS(Serving BS). In this case, attributes included in Attribute_list are number of MS and list of MS MAC Address.
— NCMS(SS/MS) to IEEE 802.16 entity (MS): This primitive is generated when the mobile management entity in the NCMS(SS/MS) decides that MS should send MOB-SCN-REQ for a request of scanning interval, perform scanning, send MOB_SCN-REP message to the Serving BS or report the scanning result to NCMS(SS/MS).

14.2.5.2.1.3.4 Effect of receipt

— NCMS(BS) to IEEE 802.16 entity (BS): When the primitive is received by a IEEE 802.16 entity (BS), the IEEE 802.16 entity (BS) shall transmit MOB_SCN-RSP to the MS to trigger the scanning procedure at the MS and generates C-HO-RSP(HO-Scan) to respond to NCMS(BS).

— NCMS(SS/MS) to IEEE 802.16 entity (MS): When the primitive is received by the IEEE 802.16 entity (MS), the MS shall perform scanning or scanning report procedure according to the parameters included in Attribute_List. If Report Target is not included in Attribute_List, the MS sends MOB_SCN-REQ message to the serving BS or starts to scan. If the report conditions defined by Link Quality Threshold and Link Status Report Period are satisfied, then the MS shall report the scanning result to NCMS(SS/MS). If only Report Target is included in Attribute_List, MS shall report the scanning result according to the value of Report Target. If Report Target is remote, the scanning report is made remotely to the BS using MOB_SCN-REP message. If Report Target is local, the scanning report is made locally to NCMS(SS/MS). The coexistence of Report Target and other attributes in Attribute_List is not allowed.

14.2.5.2.1.4 C-HO-REQ(Action_Type = HO-Mobile)

14.2.5.2.1.4.1 Function

This primitive is used by the MS or the Mobility Management Services entity in the NCMS at the MS side to indicate the initiation of the HO process. In case of MDHO/FBSS, it can be used to update Anchor BS or to add a new Active BS to the current Active set. The NCMS in the MS can use this primitive to inform the IEEE 802.16 entity (MS) to initiate the HO process and inform the serving BS of all the candidate BSs for HO as seen by the MS.

14.2.5.2.1.4.2 Semantics of the service primitive

The following parameters are included in this primitive:

```
C-HO-REQ
   (Operation_Type: Action,
    Action_Type: HO-Mobile,
    Destination: MS or NCMS,
    Attribute_list:
     Serving BSID,
     MS MAC Address,
     HO Type,
     Mode,
     Number of candidate target BSs,
     List of candidate target BSs
   )
```

**Serving BSID**
Base station unique identifier (same number as that broadcasted on the DL-MAP message).

**MS MAC Address**
48-bit unique identifier used by MS.

**HO Type**
Indication of HO types; HO or MDHO/FBSS.

**Mode**
Various modes in Anchor BS update or Active Set Update.

**Number of candidate target BSs**
Number of BSs that are recommended by the MS or BS as candidate target BSs. The information of each recommended BS is included in the list of candidate target BSs.

**List of candidate target BSs**
This is the list of recommended target BSs by the Mobility Management Services entity. The BSs in the list may be the candidate target BSs for HO or an Anchor BS or Active BSs for MDHO/FBSS according to the value of HO type and Mode. MS Access Information, Newly Allocation Information, and HO Quality Information can be included in this list.

### 14.2.5.2.1.4.3 When generated
- NCMS to IEEE 802.16 entity (MS): This primitive is used by the Mobility Management Services entity in NCMS to inform the IEEE 802.16 entity (MS) to initiate a handover.
- IEEE 802.16 entity (MS) to NCMS: This primitive is used when the MS receives the MOB_BSHO-REQ from the BS.

### 14.2.5.2.1.4.4 Effect of receipt
- IEEE 802.16 entity (MS): The MS generates MOB_MSHO-REQ MAC message to the serving BS providing it with all the candidate BSs.
- NCMS: The NCMS may instruct the MS to start the actual handover procedure (i.e., sending MOB_HO_IND).

### 14.2.5.2.2 C-HO-RSP

This primitive is used by a IEEE 802.16 entity or NCMS to respond a handover request. The Action_Type included in this primitive defines the type of handover procedure to be performed. The possible Action Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HO-Serving</td>
<td>Handover procedure between current serving BS and NCMS.</td>
</tr>
<tr>
<td>HO-Target</td>
<td>Handover procedure between target BS and NCMS</td>
</tr>
<tr>
<td>HO-Scan</td>
<td>Neighbor BS scanning procedure.</td>
</tr>
<tr>
<td>HO-Mobile</td>
<td>Handover procedure between Mobile Station and NCMS</td>
</tr>
</tbody>
</table>

The following subclauses define the primitive when its action type is set to a specific action.

### 14.2.5.2.2.1 C-HO-RSP(Action_Type = HO-Serving)

#### 14.2.5.2.2.1.1 Function

This primitive is generated by Mobility Management Services entity in NCMS or the serving IEEE 802.16 entity (BS) with the list of recommended target BSs. This primitive is sent in reply to the C-HO-REQ(HO-Serving) primitive.
14.2.5.2.2.1.2 Semantics of the service primitive

The following parameters are included in this primitive:

**C-HO-RSP**

(  
  Operation_Type: Action,  
  Action_Type: HO-Serving,  
  Destination: BS or NCMS,  
  Attribute_List:  
    MS MAC Address,  
    HO Type,  
    Mode,  
    Number of Recommended BSs,  
    Recommended target BS list  
)

**MS MAC Address**
48-bit unique identifier used by MS

**HO Type**
Indication of HO types; HO or MDHO/FBSS

**Mode**
Various modes in Anchor BS update or Active Set Update

**Number of Recommended BSs**
The number of BSs that are recommended by the MS or the serving BS as candidate target BSs. The information for each recommended BS is included in Candidate target BS list.

**Recommended target BS list**
The list shall be a subset of the candidate target BS list from the corresponding HO request. The recommended target BS list is to be delivered to the MS in the MOB_BSHO-RSP. The BSs in the list may be the candidate target BSs for HO or an Anchor BS or Active BSs for MDHO/FBSS according to the value of HO type and Mode. MS Access Information, Newly Allocation Information, and HO Quality Information can be included in this list.

14.2.5.2.2.1.3 When generated

— IEEE 802.16 entity (BS) to NCMS: This primitive is generated to respond to C-HO-REQ(HO-Serving) primitive from NCMS.
— NCMS to IEEE 802.16 entity (BS): This primitive is used when the Mobility Management Services entity in NCMS accepts or rejects the HO request from the MS. This primitive includes a list of recommended target BSs from NCMS.

14.2.5.2.2.1.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: The Mobility Management Services entity in NCMS processes the information contained in the primitive.
— NCMS to IEEE 802.16 entity (BS): The BS processes the information from this primitive and shall send MOB_BSHO-RSP to the MS.

14.2.5.2.2 C-HO-RSP(Action_Type = HO-Target)

14.2.5.2.2.2.1 Function

This primitive is used by the target IEEE 802.16 entity (BS) responding to the C-HO-REQ(HO-Target) primitive from Mobility Management Services entity in NCMS.
14.2.5.2.2.2 Semantics of the service primitive

The following parameters are included in this primitive:

**C-HO-RSP**

```plaintext
(  
  Operation_Type: Action,
  Action_Type: HO-Target,
  Destination: NCMS,
  Attribute_List:
    MS MAC Address,
    Target BSID,
    Result Flag,
    HO Type,
    Mode,
    MS Access Information,
    Newly Allocated Information,
    HO Quality Information
)
```

**Target BSID**
Base station unique identifier of the target BS

**MS MAC Address**
48-bit unique identifier used by MS

**Result Flag**

**HO Type**
Indication of HO types; HO or MDHO/FBSS

**Mode**
Various modes in Anchor BS update or Active Set Update

**MS Access Information**
Information needed by MS to access the target BS; HO ID, CQI CH Information, HO Authorization Policy Information

**Newly Allocated Information**
Newly allocated information for the MS or each service flow; SAID, CID

**HO Quality Information**
Information related with quality of HO procedure; HO Optimization Flag, Service Level Prediction

14.2.5.2.2.3 When generated

When the target IEEE 802.16 entity (BS) generates this primitive to respond to the C-HO-REQ(HO-Target) primitive from the NCMS.

14.2.5.2.2.4 Effect of receipt

The Mobility Management Services entity in NCMS processes the information contained in this primitive and may generate a primitive to the serving IEEE 802.16 entity (BS) to proceed in the HO procedure.

14.2.5.2.2.3 C-HO-RSP(Action_Type = HO-Scan)

14.2.5.2.2.3.1 Function

This primitive is issued by an IEEE 802.16 entity to respond to C-HO-REQ(HO-Scan)
14.2.5.2.2.3.2 Semantics of the service primitive

The parameters of the primitive are as follows:

**C-HO-RSP**

```plaintext
(  
  Operation_Type: Action,  
  Action_Type: HO-Scan,  
  Destination: NCMS,  
  Attribute_List:  
    Number of MS,  
    List of MS MAC Address,  
    List of Signal information,  
    Scan Duration,  
    Start Frame,  
    MIH Capability,  
    List of Neighboring BS,  
    List of Scanning Type,  
    List of Association Ranging Assignment,  
    Result Code  
)
```

- **Number of MS**
  - Number of MSs

- **List of MS MAC Address**
  - The list of MS MAC Address

- **List of Signal Information**
  - Downlink Physical Service Level,
  - Downlink RSSI mean,
  - Downlink RSSI standard deviation,
  - Downlink CINR mean,
  - Downlink CINR standard deviation,

- **Scan Duration**
  - Scan duration time

- **Start Frame**
  - Scan start frame

- **MIH Capability**
  - MIH capability of the current BS. This parameter carries the MIH capability field in the DCD message, if available.

- **List of Neighboring BS**
  - The list of neighboring BS to which the MS would like to perform association.

- **List of Scanning Type**
  - List of scanning type, 0b001, 0b010, or 0b011 corresponds to association type Level 0, 1, or 2, respectively. One scanning type for each neighboring BS.

- **List of Association Ranging Assignment**
  - Rendezvous Time,
  - Dedication Codes,
  - Transmission Opportunity Offset

- **Result Code**
  - The result of scan report message transmission. When there is no available BS to scan, ‘No Available BS’ result code shall be included.
14.2.5.2.2.3.3 When generated

— IEEE 802.16 entity (BS) to NCMS: For a IEEE 802.16 entity (BS), this primitive is generated when the BS receives C-HO-REQ(HO-Scan).
— IEEE 802.16 entity (MS) to NCMS: For a IEEE 802.16 entity (MS), this primitive is generated when one of following events are occurred:
  1) The MS receives MOB-SCN-RSP message.
  2) One of conditions for scanning report defined C-HO-REQ(Scan) is satisfied.
  3) The MS receives C-HO-REQ(Scan) primitive with Report Target = remote and sends MOB_SCN-REP message to BS.
  4) The MS receives C-HO-REQ(Scan) primitive with Report Target = local.

14.2.5.2.2.3.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: The Mobility Management Services entity in NCMS may decide the specific MS and its potential target BS for BS-initiated HO based on the reported signal quality in the C-HO-RSP(HO-Scan) primitive.
— IEEE 802.16 entity (MS) to NCMS: The Mobility Management Services entity in NCMS may instruct MS to start to scan or to handover to the selected BS based on the information from C-HO-RSP(HO-Scan).

14.2.5.2.2.4 C-HO-RSP(Action_Type = HO-Mobile)

14.2.5.2.2.4.1 Function

This primitive is used by the MS to inform the Mobility Management Services entity in the NCMS MS about the arrival of a MOB-BSHO_RSP MAC message in response to the previously generated MOB_MSHO-REQ message and the pruned down list of the candidate BSs selected by the Mobility Management in the NCMS for the upcoming actual HO phase.

14.2.5.2.2.4.2 Semantics of the service primitive

The following parameters are included in this primitive:

C-HO-RSP

( Operation_Type: Action,
  Action_Type: HO-Mobile,
  Destination: NCMS,
  Attribute_list:
    Serving BSID,
    MS MAC Address,
    HO Type,
    Number of candidate target BSs,
    List of candidate target BSs )

Serving BSID
Base station unique identifier (same number as that broadcasted on the DL-MAP message).

MS MAC Address
48-bit unique identifier used by MS.

HO Type
Indication of HO types; HO or MDHO/FBSS.

**Mode**
Various modes in Anchor BS update or Active Set Update.

**Number of candidate target BSs**
Number of BSs that are recommended by the MS or BS as candidate target BSs. The information of each recommended BS is included in the list of candidate target BSs.

**List of candidate target BSs**
This is the list of recommended target BSs by the Mobility Management Services entity. The BSs in the list may be the candidate target BSs for HO or an Anchor BS or Active BSs for MDHO/FBSS according to the value of HO type and Mode. MS Access Information, Newly Allocation Information, and HO Quality Information can be included in this list.

14.2.5.2.2.4.3 When generated
This primitive is used by the IEEE 802.16 entity (MS) to inform the Mobility Management Services entity about the arrival of a response to the previously generated C-HO-REQ(HO-Mobile) primitive.

14.2.5.2.2.4.4 Effect of receipt
The NCMS learns about the pruned down list of the potential candidates BS to select as the final candidate.

14.2.5.2.3 C-HO-IND
This primitive is used by a BS or NCMS to notify the other entity of a handover event. The possible Event_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HO-Start</td>
<td>Indicating the MS is ready to handover from the current serving BS to the target BS</td>
</tr>
<tr>
<td>HO-Cancel</td>
<td>Indicating the current HO procedure is cancelled</td>
</tr>
<tr>
<td>HO-Scan</td>
<td>Providing scanning result to NCMS</td>
</tr>
<tr>
<td>HO-CMPLT</td>
<td>Indicating MS network re-entry completion at the target BS</td>
</tr>
</tbody>
</table>

The following subclauses define the primitive when its event type is set to a specific action.

14.2.5.2.3.1 C-HO-IND (Event_Type = HO-Start)

14.2.5.2.3.1.1 Function
In case of HO, this primitive is used to indicate the starting of the actual HO. In case of MDHO/FBSS, it can be used to update Anchor BS or to add a new Active BS to the current Active set. Both the serving IEEE 802.16 entity (BS) and the Mobility Management Services entity in the NCMS can use this primitive to inform the IEEE 802.16 target BS entity or the Mobility Management Services entity in the NCMS of the actual HO starting process. In addition, the Mobility Management Services entity in the NCMS at MS side can use this primitive to inform the IEEE 802.16 entity (MS) about the actual HO starting process.

14.2.5.2.3.1.2 Semantics of the service primitive
The following parameters are included in this primitive:
C-HO-IND

(  
Event_Type: HO-Start,  
Destination: BS, MS, or NCMS,  
Attribute_List:  
   MS MAC Address,  
   HO Type,  
   Mode,  
   Target BSID
)

MS MAC Address  
48-bit unique identifier used by MS

HO Type  
Indication of HO types; HO or MDHO/FBSS

Mode  
Various modes in Anchor BS update or Active Set Update

Target BSID  
Base station unique identifier to which the MS attempts the actual HO

14.2.5.2.3.1.3 When generated

— IEEE 802.16 entity (BS) to NCMS: This primitive is generated when MOB_HO-IND is received from the MS.
— NCMS to IEEE 802.16 entity (BS): This primitive is used by the Mobility Management Services entity in NCMS to inform the target IEEE 802.16 entity (BS) the start of the MS handover.
— IEEE 802.16 entity (MS) to NCMS: This primitive is generated after the MS sends MOB_HO-IND message to start the actual HO.
— NCMS to IEEE 802.16 entity (MS): This primitive is generated by NCMS to request the MS to start the HO by sending MOB_HO-IND message to the serving BS.

14.2.5.2.3.1.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: The Mobility Management Services entity in NCMS processes the information contained in the primitive and may generate C-HO-IND (HO-Start) to the target IEEE 802.16 entity (BS).
— NCMS to IEEE 802.16 entity (BS): The target IEEE 802.16 entity (BS) prepares for the MS handover as indicated in this primitive.
— IEEE 802.16 entity (MS) to NCMS: The NCMS prepares the network re-entry with the target BS.
— NCMS to IEEE 802.16 entity (MS): The MS transmits MOB_HO-IND message to the serving BS to start the HO.

14.2.5.2.3.2 C-HO-IND (Event_Type = HO-Cancel)

14.2.5.2.3.2.1 Function

In case of HO, this primitive indicates the cancellation of the pending HO. In case of MDHO/FBSS, it can be used to cancel anchor BS update or Active set update, or to remove a target BS from the current active set. Both of the serving IEEE 802.16 entity and the Mobility Management Services entity in NCMS can use this primitive.

14.2.5.2.3.2.2 Semantics of the service primitive

This primitive conveys the following parameters:
C-HO-IND

( 
Event_Type: HO-Cancel,
Destination: BS, MS, or NCMS,
Attribute_List:
MS MAC Address,
HO Type,
Mode
)

MS MAC Address
48-bit unique identifier used by MS

HO Type
Indication of HO type; HO and MDHO/FBSS

Mode
It is valid for MDHO/FBSS and cancels Anchor BS update or Active set update. In addition, it may indicate removal of the target BS from the current active set.

14.2.5.2.3.2.3 When generated

— IEEE 802.16 entity (BS) to NCMS: This primitive is generated when MOB_HO-IND is received from the MS.
— NCMS to IEEE 802.16 entity (BS): This primitive is used by the Mobility Management Services entity in NCMS to inform the target IEEE 802.16 entity (BS) the HO procedure is cancelled.
— IEEE 802.16 entity (MS) to NCMS: This primitive is generated after the MS sends MOB_HO-IND message to cancel the actual HO.
— NCMS to IEEE 802.16 entity (MS): This primitive is generated by NCMS to request the MS to cancel the HO by sending MOB_HO-IND message to the serving BS

14.2.5.2.3.2.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: The Mobility Management Services entity in NCMS processes the information contained in the primitive and may generate C-HO-IND (HO-Cancel) to the target IEEE 802.16 entity (BS).
— NCMS to IEEE 802.16 entity (BS): The target IEEE 802.16 entity (BS) shall release all resources related to the MS handover.
— IEEE 802.16 entity (MS) to NCMS: The NCMS completes HO cancellation procedure.
— NCMS to IEEE 802.16 entity (MS): The MS transmits MOB_HO-IND message to the serving BS to cancel the HO.

14.2.5.2.3.3 C-HO-IND (Event_Type = HO-Scan)

14.2.5.2.3.3.1 Function

On the uplink, this primitive is used to indicate the reception of MOB_SCN-REP message from the MS. The IEEE 802.16 entity (BS) uses this primitive to report MS radio information to the NCMS.

On the downlink, this primitive is used by the NCMS to forward the ranging parameters to the IEEE 802.16 entity (BS) in order to trigger the MOB_ASC-REP message, and by the IEEE 802.16 entity (MS) to forward the ranging parameters to the NCMS.

14.2.5.2.3.3.2 Semantics of the service primitive

The following parameters are included in this primitive:
C-HO-IND

(  
  Event_Type: HO-Scan,  
  Destination: NCMS, BS, MS,  
  Attribute_List:  
    MS MAC Address,  
    RF Signal information,  
    List of Neighboring BS,  
    List of Association Ranging Parameters  
)

MS MAC Address
48-bit unique identifier used by MS

RF Signal Information
Downlink signal information measured by the MS; DL CINR mean, DL RSSI mean, Relative delay, BS RTD, etc.

List of Neighboring BS
The list of neighboring BS reporting association ranging parameters.

List of Association Ranging Parameters
PHY offset (Timing adjust, power level adjust, SLP, etc.).

14.2.5.2.3.3 When generated

— IEEE 802.16 entity (BS) to NCMS: This primitive is generated by IEEE 802.16 entity (BS) when it receives a MOB_SCAN-REP.
— NCMS to IEEE 802.16 entity (BS): This primitive may be generated by the NCMS of the IEEE 802.16 entity (serving BS) after it has collected and aggregated association ranging parameters from the neighboring BSs.
— IEEE 802.16 entity (MS) to NCMS: This primitive is generated by the IEEE 802.16 entity (MS) to forward the ranging parameters to the NCMS.

14.2.5.2.3.4 Effect of receipt

— IEEE 802.16 entity (BS) to NCMS: NCMS processes the information and may decide to trigger a BS-initiated handover.
— NCMS to IEEE 802.16 entity (BS): This primitive will trigger the IEEE 802.16 entity (BS) to trigger the MOB_ASC-REP message.
— IEEE 802.16 entity (MS) to NCMS: The NCMS(MS) will store the ranging parameters as association records.

14.2.5.2.3.4 C-HO-IND (Event_Type = HO-CMPLT)

14.2.5.2.3.4.1 Function

This primitive is used by both BS and NCMS to notify the handover process is completed.

14.2.5.2.3.4.2 Semantics of the service primitive

It delivers the following parameters:

C-HO-IND

(  
  Event_Type: HO-CMPLT,  
)
Destination: NCMS or BS,
Attribute_List:
   Target BSID,
   MS MAC Address,
   List of Last received SDU SNs

Target BSID
   Base station unique identifier of the target BS
MS MAC Address
   48-bit unique identifier used by MS
List of Last received SDU SNs
   (SFID
    Last received SDU SN
  )

The sequence number of the last MAC SDU that the MS received before handover to the target
BS. The connection associated with the SDU SN is identified by SFID when SDU SN feedback
is enabled.

14.2.5.2.3.4.3 When generated

   — IEEE 802.16 entity (BS) to NCMS: This primitive is generated by target IEEE 802.16 entity (BS)
     when the MS completes network re-entry at the target BS. If SDU SN feedback is enabled, the target
     IEEE 802.16 entity (BS) shall generates this primitive after it has received the SN report header.
   — NCMS to IEEE 802.16 entity (BS): This primitive is generated by the NCMS after finishing
     handover process in the NCMS side. It is used to inform serving BS to release its corresponding
     resource.

14.2.5.2.3.4.4 Effect of receipt

   — IEEE 802.16 entity (BS) to NCMS: NCMS completes handover procedure.
   — NCMS to IEEE 802.16 entity (BS): The Serving BS releases its resource for the MS accordingly.

14.2.5.3 MIH control protocol procedures

The MIH Control Primitives provide transport of IEEE 802.21 MIHF frames between the IEEE 802.16
entity and the NCMS. This enables the NCMS to map between MIHF frames and primitives on the IEEE
802.21 MIH-SAP, consistent with 5.5.3 of IEEE Std 802.21.
14.2.5.3.1 C-MIH-IND

14.2.5.3.1.1 Function

This primitive used by the IEEE 802.16 entity to indicate on the C-SAP the reception of a MOB_MIH-MSG on the air interface and to convey the IEEE 802.21 MIHF frame carried in the message to the NCMS.

This primitive is used by the NCMS to request on the C-SAP that the IEEE 802.16 entity transmits a MOB_MIH-MSG message containing the IEEE 802.21 MIHF frame carried in the primitive.

14.2.5.3.1.2 Semantics of the service primitive

**C-MIH-IND**

```python
(   Event_Type: MIH-IND,
    Destination: NCMS, BS, MS,
    Attribute_List:   MIHF frame,
)
```

**MIHF frame**

MIHF frame as described in 8.2 of IEEE Std 802.21
14.2.5.3.1.3 When generated

— IEEE 802.16 entity to NCMS: This primitive is generated by the IEEE 802.16 entity when the IEEE 802.16 entity receives a MOB_MIH-MSG from a peer IEEE 802.16 entity.
— NCMS to IEEE 802.16 entity: This primitive is generated by the NCMS when the NCMS needs to convey an IEEE 802.21 MIHF frame through the IEEE 802.16 entity to a peer IEEE 802.16 entity.

14.2.5.3.1.4 Effect of receipt

— IEEE 802.16 entity to NCMS: On receipt of this primitive from the C-SAP by the NCMS, the NCMS should map the IEEE 802.21 MIH Message embedded in the IEEE 802.21 MIHF frame in the primitive onto the equivalent primitive on the MIH_SAP consistent with IEEE Std 802.21, 5.5.3.
— NCMS to IEEE 802.16 entity: On receipt of this primitive from the C-SAP by the IEEE 802.16 entity, the IEEE 802.16 entity shall transmit a MOB_MIH-MSG message containing the IEEE 802.21 MIHF frame conveyed in the MIHF frame field of the primitive.

14.2.6 Radio resource management

The RRM Primitives are a set of primitives for supporting RRM procedures between BS and NCMS.
The Radio Resource Controller (RRC) may use this primitive to request a BS to provide spare capacity information to the RRC or to provide a report of the link level quality for a specific MS. The possible Action_Types for this primitive are listed in the following table:
14.2.6.1.1 C-RRM-REQ (Action_Type = Spare Capacity Report)

14.2.6.1.1 Function

This primitive shall be used by NCMS (BS side) to request the BS to send spare capacity information periodically or event driven.

14.2.6.1.1.1 Semantics of the service primitive:

The parameters of the primitives are as follows:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spare Capacity Report</td>
<td>Report the spare capacity information</td>
</tr>
<tr>
<td>PHY report</td>
<td>Report the link level quality for a specific MS</td>
</tr>
</tbody>
</table>

**C-RRM-REQ**

```plaintext
( 
  Operation_Type: Action, 
  Action_Type: Spare Capacity Report, 
  Destination: BS, 
  Attribute_List: 
    Spare Capacity Report Type, 
    Report Characteristics, 
    Reporting Period P, 
    Reporting Threshold RT 
)
```

**Spare Capacity Report Type**

Type of requested report profile. 1 for spare capacity report type 1. (Types > 1 reserved for future types)

**Report Characteristics**

Bitmap. Indicates whether report shall be sent periodically, or event driven. It also indicates whether the report shall include the details about permutation zones and subchannels. Following events are possible (separate or in combination), which may be selected by setting the respective bit:

- Bit 0: Periodically as defined by reporting period P.
- Bit 1: Regularly whenever resources have changed as defined by RT since the last measurement report.
- Bit 2: Reporting shall be given per permutation zones.
- Bit 3: Change of Radio Resources Allocation.

The event “Change of Radio Resources Allocation” means that a report shall be given whenever any of the following parameters at the BS have changed:

- N_PERMUTATION_ZONES
- OFDMA symbol offset
- Permutation Scheme
- Permutation Zone Subchannels Bitmap

**Reporting Period P**

The Time P is used by BS (RRA) as the reporting period for producing the information requested by RRC.

**Reporting Threshold RT**
The threshold value RT shall be used by BS (RRA) to send another Spare Capacity report as soon as the spare capacity increases or decreases by more than that threshold value.

14.2.6.1.1.2 When generated

The NCMS at BS side may use this primitive to order a BS to send periodic and/or event-driven radio resource capacity reports.

14.2.6.1.1.3 Effect of receipt

The BS shall respond with a C-RRM-RSP (Spare Capacity Report) and, if applicable, one or more subsequent periodic or event-driven C-RRM-IND (Spare Capacity Report) primitives.

14.2.6.1.2 C-RRM-REQ (Action_Type = PHY report)

14.2.6.1.2.1 Function

The Radio Resource Controller (RRC) may use this primitive to request a BS to provide a report of the link level quality for a specific MS.

14.2.6.1.2.2 Semantics of the service primitive:

\[
\text{C-RRM-REQ} \\
\quad ( \\
\quad \quad \text{Operation_Type: Action,} \\
\quad \quad \text{Action_Type: PHY Report,} \\
\quad \quad \text{Destination: BS,} \\
\quad \quad \text{Attribute_List:} \\
\quad \quad \quad \text{MS MAC Address} \\
\quad ) \\
\]

\text{MS MAC Address} \\
48-bit unique identifier of the MS

14.2.6.1.2.3 When generated

The NCMS at BS side may use this primitive at any time to order a BS to report on the PHY channel parameters (RSSI, CINR as well as spectral efficiency as expressed by the Physical Service Level) for a specific MS.

14.2.6.1.2.4 Effect of receipt

The BS shall generate the required UL channel measurements and shall request the SS via MAC Management messages to send the required DL channel measurement reports to the BS; once the measured values are available, the BS shall forward these to the NCMS (BS side) by a C-RRM-RSP (PHY report) primitive.

14.2.6.2 C-RRM-RSP

The BS may use this primitive to report spare capacity information to the RRC, as requested by the RRC within the Spare Capacity Request primitive. Or the BS may use this primitive to provide a report of the link level quality for a specific MS to the Radio Resource Controller (RRC). The possible Action_Types for this primitive are listed in the table below:
14.2.6.2.1 C-RRM-RSP(Action_Type = Spare Capacity Report)

14.2.6.2.1.1 Function

The BS may use this primitive to provide spare capacity information to the RRC, as requested by the RRC within the Spare Capacity Request primitive. The BS may also use this primitive to inform the RRC about preferred Radio Resources used for transmission at this BS, using the attribute Permutation Zone Subchannels Bitmap.

14.2.6.2.1.2 Semantics of the service primitive:

<table>
<thead>
<tr>
<th>Action_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spare Capacity Report</td>
<td>Report the spare capacity information</td>
</tr>
<tr>
<td>PHY report</td>
<td>Report the link level quality for a specific MS</td>
</tr>
</tbody>

### C-RRM-RSP

```plaintext
( Operation_Type: Action, Action_Type: Spare Capacity Report, Destination: NCMS, Attribute_List:
  Spare Capacity Report Type,
  N_PERMUTATION_ZONES,
  For all Permutation Zones:
    OFDMA symbol offset,
    Permutation scheme,
    Permutation Zone Subchannels Bitmap,
    Available Radio Resource,
    Radio Resource Fluctuation )
```

**Spare Capacity Report Type**

Type of report profile = 1

**N_PERMUTATION_ZONES**

Number of radio frame subsections for which the spare capacity will be indicated. A value of 1 indicates that the entire DL and UL radio subframe is considered to be a single permutation zone each, in which case the DL/UL Available Radio Resource indicators cover the full DL and UL radio subframes.

**OFDMA symbol offset**

Denotes the start of the zone (counting from the frame preamble and starting from 0)

**Permutation scheme**

Denotes permutation scheme used in current permutation zone. The following types are possible:

- DL PUSC permutation
- DL FUSC permutation
- DL Optional FUSC permutation
- DL AMC
- DL TUSC1
- DL TUSC2
- UL PUSC
- UL AMC

**Permutation Zone Subchannels Bitmap**
 Indicates the subchannels preferred for transmission in this Permutation Zone at the respective BS.

**Available Radio Resource**
 Percentage of reported average available subchannels and symbols resources ("slots") per frame. If N_PERMUTATION_ZONES > 1, the indicator covers a permutation zone instead of the entire DL or UL radio subframe.

**Radio Resource Fluctuation**
 Radio Resource Fluctuation is used to indicate the degree of fluctuation in DL and UL channel data traffic throughputs. If N_PERMUTATION_ZONES > 1, the indicator covers a permutation zone instead of the radio frame. When Radio Resource Fluctuation is set to 0, it implies that the DL and UL data traffic is constant in data throughput. Hence, there is no fluctuation in Available Radio Resource. When Radio Resource Fluctuation is set to maximum value 255, the data traffic is very volatile in nature, which makes the Available Radio Resource unpredictable. The Radio Resource Fluctuation for all traffic models should be in the range of 0 to 255.

### 14.2.6.2.1.3 When generated
The BS shall send this primitive in response to a C-RRM-REQ (Spare Capacity Report) received from the NCMS.

### 14.2.6.2.1.4 Effect of receipt
The NCMS may use the received Spare Capacity information about the BSs for several purposes, e.g., for forwarding the aggregated BS capacity information to all the BSs by means of the C-RRM-IND (Neighbor-BS Radio Resource Status Update) primitive, for Service Flow Admission Control, or for reconfiguring the allocated BS resources.

### 14.2.6.2.2 C-RRM-RSP(Action_Type = PHY Report)

#### 14.2.6.2.2.1 Function
The BS may use this primitive to provide a report of the link level quality for a specific MS to the Radio Resource Controller (RRC).

#### 14.2.6.2.2.2 Semantics of the service primitive:

**C-RRM-RSP**

```plaintext

Uplink RSSI standard deviation,
Uplink CINR mean,
Uplink CINR standard deviation

Downlink Physical Service Level
Channel rate available for the MS calculated as a multiple of 1/32 of nominal bandwidth in the correspondent direction assuming 1 bit/Hz. For example, if DL channel bandwidth is 10 MHz, value PSL=4 means $4 \times \frac{1}{32} \times 10 \text{ Mbps} = 1.25 \text{ Mbps}$. 1 PSL 96 (Number of subchannels in different OFDMA modes is multiple of 16 or 32; highest modulation (QAM64) provides 3 bits/Hz)

Downlink RSSI mean
As specified in 8.1.9 Channel quality measurements.

Downlink RSSI standard deviation
As specified in 8.1.9 Channel quality measurements.

Downlink CINR mean
As specified in 8.1.9 Channel quality measurements.

Downlink CINR standard deviation
As specified in 8.1.9 Channel quality measurements.

Uplink Physical Service Level
Channel rate available for the MS calculated as a multiple of 1/32 of nominal bandwidth in the correspondent direction assuming 1 bit/Hz. (see definition of Downlink Physical Service Level)

Uplink RSSI mean
As specified in 8.1.9 Channel quality measurements.

Uplink RSSI standard deviation
As specified in 8.1.9 Channel quality measurements.

Uplink CINR mean
As specified in 8.1.9 Channel quality measurements.

Uplink CINR standard deviation
As specified in 8.1.9 Channel quality measurements.

14.2.6.2.2.3 When generated
The BS shall send this primitive in response to a C-RRM-REQ (PHY Report) received from the NCMS, after having retrieved the required PHY channel measurement data.

14.2.6.2.2.4 Effect of receipt
The NCMS may use the received PHY Report data of the respective MS for any purpose, e.g., as a reason for initiating handovers or service flow modifications.

14.2.6.3 C-RRM-IND
This primitive can be used by RRC to inform a Serving BS about the list of Neighbor BSs that are potential HO Target Base Stations for any MS's being served by the SBS, including an information about their radio resource status. And it can also be used by the RRA to report the spare capacity information to the RRC periodically or as event driven. The possible event types for this primitive are listed in the table below:
14.2.6.3.1 C-RRM-IND (Event_Type = Spare Capacity Report)

14.2.6.3.1.1 Function

The primitive provides the mechanism to report the spare capacity information to the RRC whenever this is not the immediate response to a report solicitation from RRC.

14.2.6.3.1.2 Semantics of the service primitive:

<table>
<thead>
<tr>
<th>Event_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spare Capacity Report</td>
<td>Report the spare capacity information</td>
</tr>
<tr>
<td>Neighbor-BS Radio Resource Status Update</td>
<td>Inform neighbor list BS's list or related information about the radio resource status</td>
</tr>
</tbody>
</table>

Spare Capacity Report Type

Type of report profile = 1

N_PERMUTATION_ZONES

Number of radio frame subsections for which the spare capacity will be indicated. A value of 1 indicates that the entire DL and UL radio subframe is considered to be a single permutation zone each, in which case the DL/UL Available Radio Resource indicators cover the full DL and UL radio subframes.

OFDMA symbol offset

Denotes the start of the zone (counting from the frame preamble and starting from 0)

Permutation scheme

Denotes permutation scheme used in current permutation zone. The following types are possible:
- DL PUSC permutation
- DL FUSC permutation
- DL Optional FUSC permutation
- DL AMC
- DL TUSC1
- DL TUSC2
- UL PUSC
- UL AMC

Permutation Zone Subchannels Bitmap
Indicates the subchannels preferred for transmission in this Permutation Zone at the respective BS.

**Available Radio Resource**

Percentage of reported average available subchannels and symbols resources (“slots”) per frame. If \(N_{PERMUTATION\_ZONES} > 1\), the indicator covers a permutation zone instead of the entire DL or UL radio subframe.

**Radio Resource Fluctuation**

Radio Resource Fluctuation is used to indicate the degree of fluctuation in DL and UL channel data traffic throughputs. If \(N_{PERMUTATION\_ZONES} > 1\), the indicator covers a permutation zone instead of the radio frame. When Radio Resource Fluctuation is set to 0, it implies that the DL and UL data traffic is constant in data throughput. Hence, there is no fluctuation in Available Radio Resource. When Radio Resource Fluctuation is set to maximum value 255, the data traffic is very volatile in nature, which makes the Available Radio Resource unpredictable. The Radio Resource Fluctuation for all traffic models should be in the range of 0 to 255.

### 14.2.6.3.1.3 When generated

The BS shall use this primitive for delivering a periodic or event-triggered Spare Capacity Report which is not the immediate response to a C-RRM-REQ (Spare Capacity Report) received from the NCMS.

### 14.2.6.3.1.4 Effect of receipt

The NCMS may use the received Spare Capacity information for any purpose, similarly as in case of a received C-RRM-RSP (Spare Capacity Report).

### 14.2.6.3.2 C-RRM-IND (Event_Type = Neighbor-BS Radio Resource Status Update)

#### 14.2.6.3.2.1 Function

This primitive can be used by RRC to inform a Serving BS about the list of Neighbor BSs which are potential HO Target Base Stations for any MS's being served by the SBS, including the information about their radio resource status. This primitive can also be used by RRC in NCMS to enforce a change of the Permutation Zone parameters for a group of BSs. For this purpose, the NCMS may send this C-RRM-IND message to each of the BSs in the group in a synchronized way, thereby informing each BS about i) the Permutation Zone parameters to be used by this BS, and ii) the Permutation Zone Parameters of neighboring BSs, together with an indication about the percentage of still available radio resources in these Permutation Zones. The BS may use this detailed neighbor BS information at the MAC layer for optimized scheduling.

#### 14.2.6.3.2.2 Semantics of the service primitive:

**C-RRM-IND**

(  
  Event_Type: Neighbor-BS Radio Resource Status Update,  
  Destination: BS,  
  Attribute_List:  
    N\_NEIGHBORS,  
    For all BSs in the BS List:  
      BSID,  
    N\_PERMUTATION\_ZONES,  
    For all Permutation Zones:  
      OFDMA symbol offset,  
      Permutation scheme,  
      Permutation Zone Subchannels Bitmap,  
)
Available Radio Resource,
Radio Resource Fluctuation,
DCD Configuration Change Count,
UCD Configuration Change Count

N NEIGHBORS
Number of neighbor BS's

BSID
Unique identifier of BS

N_PERMUTATION_ZONES
Number of radio frame subsections for which the spare capacity will be indicated. A value of 1 indicates that the entire DL and UL radio subframe is considered to be a single permutation zone each, in which case the DL/UL Available Radio Resource indicators cover the full DL and UL radio subframes.

OFDMA symbol offset
Denotes the start of the zone (counting from the frame preamble and starting from 0)

Permutation scheme
Denotes permutation scheme used in current permutation zone. The following types are possible:
- DL PUSC permutation
- DL FUSC permutation
- DL Optional FUSC permutation
- DL AMC
- DL TUSC1
- DL TUSC2
- UL PUSC
- UL AMC

Permutation Zone Subchannel Bitmap
Indicates the subchannels available for transmission in this Permutation Zone at the respective BS.

Available Radio Resource
Percentage of reported average available subchannels and symbols resources per frame. If N_PERMUTATION_ZONES > 1, the indicator covers a permutation zone instead of the entire DL or UL radio subframe.

Radio Resource Fluctuation
Radio Resource Fluctuation is used to indicate the degree of fluctuation in DL and UL channel data traffic throughputs. If N_PERMUTATION_ZONES > 1, the indicator covers a permutation zone instead of the radio frame. When Radio Resource Fluctuation is set to 0, it implies that the DL and UL data traffic is constant in data throughput. Hence, there is no fluctuation in Available Radio Resource. When Radio Resource Fluctuation is set to maximum value 255, the data traffic is very volatile in nature which makes the Available Radio Resource unpredictable. The Radio Resource Fluctuation for all traffic models should be in the range of 0 to 255.

DCD Configuration Change Count
This represents the Neighbor BS current Downlink Channel Descriptor (DCD) configuration change count

UCD Configuration Change Count
This represents the Neighbor BS current Uplink Channel Descriptor (UCD) configuration change count
14.2.6.3.2.3 When generated

The NCMS (BS side) shall use this primitive to forward aggregated Neighbor BS information to each of the BSs which are under control of the NCMS.

14.2.6.3.2.4 Effect of receipt

The BS shall use the information for updating the MOB_NBR-ADV message at the radio interface. In addition the BS may use the information for improving the efficiency of its MAC and PHY functions.

14.2.7 Network entry & exit management

The Network Entry & Exit Management Primitives are a set of primitives for supporting network entry, network re-entry, and network exit procedures between IEEE 802.16 entity and NCMS. Network entry and exit management uses the Service Flow Management Services in the NCMS. The exception are the neighbor BS update primitives which use the Mobility Management Services.

Figure 372—Network Deregistration Primitives by BS
### 14.2.7.1 C-NEM-REQ

This primitive is used by the NCMS or the IEEE 802.16 entity to control ranging or registration network entry procedures. The Action_Type included in this primitive defines the type of network entry procedures to be performed. The possible Action_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ranging</td>
<td>Ranging procedures between IEEE 802.16 entity and NCMS</td>

<tr>
<td>Deregistration</td>
<td>Deregistration procedures between IEEE 802.16 entity and NCMS</td>
</tr>
</tbody>
</table>

#### 14.2.7.1.1 C-NEM-REQ (Action_Type = Ranging)

#### 14.2.7.1.1.1 SS side

#### 14.2.7.1.1.1.1 Function

This primitive requests ranging. Upper layer management entities in NCMS shall request ranging by sending this primitive to the SS.

#### 14.2.7.1.1.1.2 Semantics:

```c
C-NEM-REQ
    (Operation_Type: Action,
     Action_Type: Ranging,
     Destination: SS,
     Attribute_List:
       Ranging Type)
```

**Ranging Type**
This identifies the ranging type; value range:
- Initial
- Handoff
- Periodic

#### 14.2.7.1.1.3 When generated

This primitive is generated by the upper layer management entities to initiate ranging procedure for initial network entry, network re-entry after handover and periodic ranging.

#### 14.2.7.1.1.4 Effect of receipt

MAC layer shall generate CDMA code or RNG-REQ MAC management message including corresponding TLVs depending on the Ranging type and RNG-REQ message shall be sent to the BS over the air interface.
14.2.7.1.1.2 BS side

14.2.7.1.1.2.1 Function

This primitive notifies the upper layer management entity in the BS that the mobile terminal requests ranging with RNG-REQ.

14.2.7.1.1.2.2 Semantics:

C-NEM-REQ

( Operation_Type: Action,
  Action_Type: Ranging,
  Destination: NCMS,
  Attribute_List:
    SS Address,
    MAC Version,
    Required Downlink Burst Profile,
    Serving BSID,
    HO Indication
  )

SS Address
  MAC Address of SS that requests ranging

MAC Version
  MAC version supported by SS; value range:
  IEEE Std 802.16-2001,
  IEEE Std 802.16-2004,
  IEEE Std 802.16e-2005,
  IEEE Std 802.16g-2007

Required Downlink Burst Profile
  DIUC value of Downlink Burst Profile

Serving BSID
  Serving BSID during ranging

HO Indication
  This parameter indicates the SS is currently attempting to HO; value range:
  NULL,
  HO,
  Fast HO,
  Entry from Idle Mode

14.2.7.1.1.2.3 When generated

This primitive is generated by MAC layer when MAC layer receives RNG-REQ message over the air interface.

14.2.7.1.1.2.4 Effect of receipt

Upon receipt ranging indication, C-NEM-RSP is generated
14.2.7.1.2 C-NEM-REQ (Action_Type = SS Basic Capability)

14.2.7.1.2.1 Function

This primitive is initiated by the upper layer entity to request SBC (SS Basic Capability).

14.2.7.1.2.2 Semantics:

C-NEM-REQ
(  
  Operation_Type: Action,  
  Action_Type: SS Basic Capability,  
  Destination: SS or NCMS,  
  Attribute_List:  
    SS MAC Address,  
    Authorization Policy,  
    Service Information Query (SIQ)  
)

SS MAC Address
48-bit MAC Address which identify SS.

Authorization Policy
Enumerated type which indicates authorization policy used by SS and BS. The value can be assigned to No Authorization, Only EAP-based authorization, Only RSA-based authorization, or EAP-based authorization after RSA-based authorization.

Service Information Query
1-Byte Service Information Query to request the Service Network Provider Identifiers supported by the Operator Network that includes the current BS.

14.2.7.1.2.3 When generated

— NCMS to IEEE 802.16 entity (SS): This primitive is generated by NCMS at SS after receiving ranging response message.
— IEEE 802.16 entity (BS) to NCMS: This primitive is also generated by BS when the BS receives SBC-REQ message over the air interface.

14.2.7.1.2.4 Effect of receipt

— NCMS to IEEE 802.16 entity (SS): The IEEE 802.16 entity (SS) generates SBC-REQ MAC message when it receives C-NEM-REQ(SS Basic Capability).
— IEEE 802.16 entity (BS) to NCMS: The NCMS at BS processes the information from this primitive and shall generate C-NEM-RSP(SS Basic Capability).

14.2.7.1.3 C-NEM-REQ (Action_Type = Registration)

14.2.7.1.3.1 SS side

14.2.7.1.3.1.1 Function

This primitive is initiated by the upper layer entity to request registration.

14.2.7.1.3.1.2 Semantics:

C-NEM-REQ
IP Management Mode
The IP management mode parameter dictates whether the provider intends to manage the SS on an ongoing basis via IP-based mechanisms; value range:
Unmanaged mode,
IP-managed mode

IP Version
IP version

Method of Allocating IP Address
IP Address Configuration method; value range:
DHCPv4,
Mobile IPv4,
DHCPv6,
Mobile IPv6,
IPv6 stateless address auto configuration

Previous IP Address
Previously assigned IP Address of SS on the secondary management connection. If not previously assigned, the value is 0.

14.2.7.1.3.1.3 When generated
This primitive is generated when upper layer entity requests registration

14.2.7.1.3.1.4 Effect of receipt
REG-REQ message including necessary TLV parameter is sent

14.2.7.1.3.2 BS side

14.2.7.1.3.2.1 Function
This primitive notifies that upper layer entity requests registration

14.2.7.1.3.2.2 Semantics:

C-NEM-REQ

( Operation_Type: Action,
  Action_Type: Registration,
  Destination: NCMS,
  Attribute_List:
    IP management mode,
    IP Version,)
Method of Allocating IP Address,
Previous IP Address

IP Management Mode
The IP management mode parameter dictates whether the provider intends to manage the SS on an ongoing basis via IP-based mechanisms; value range:
- Unmanaged mode,
- IP-managed mode

IP Version
IP version

Method of Allocating IP Address
IP Address Configuration method; value range:
- DHCPv4,
- Mobile IPv4,
- DHCPv6,
- Mobile IPv6,
- IPv6 stateless address auto configuration

Previous IP Address
Previously assigned IP Address of SS on the secondary management connection. If not previously assigned, the value is 0.

14.2.7.1.3.2.3 When generated
This primitive is generated when IEEE 802.16 entity (BS) receives REG-REQ message.

14.2.7.1.3.2.4 Effect of receipt
The NCMS shall respond to this primitive with C-NEM-RSP (Registration) primitive.

14.2.7.1.4 C-NEM-REQ (Action_Type = Deregistration)

14.2.7.1.4.1 Function
This primitive is used by NCMS at SS side to trigger the deregistration procedure. In this case, IEEE 802.16 entity at BS notifies NCMS of deregistration request when it receives DREG-REQ message from the SS. This primitive is also used by NCMS at BS side to trigger deregistration procedure. It is also used by the IEEE 802.16 entity at SS to notify NCMS of deregistration request when it receives DREG-CMD message from the BS.

14.2.7.1.4.2 Semantics:

C-NEM-REQ
(  
  Operation_Type: Action,
  Action_Type: Deregistration,
  Destination: SS, BS or NCMS,
  Attribute_List:
    SS MAC Address,
    Action Code
)

SS MAC Address
48-bit MAC Address which identifies SS.

**Action Code**
Indication of deregistration type.

### 14.2.7.1.4.3 When generated

- **NCMS(SS) to IEEE 802.16 entity (SS):**
  This primitive is generated when a higher layer entity in NCMS at SS wants to de-register the service from IEEE 802.16 networks. It is also generated by the IEEE 802.16 entity (BS) to notify NCMS of deregistration request when it receives DREG-REQ message from the SS.

- **NCMS(BS) to IEEE 802.16 entity (BS):**
  This primitive is generated when a higher layer entity in NCMS at BS wants to de-register the service from IEEE 802.16 networks. It is also generated by the IEEE 802.16 SS entity to notify NCMS of deregistration request when it receives DREG-CMD message from the BS.

### 14.2.7.1.4.4 Effect of receipt

- **NCMS(SS) to IEEE 802.16 entity (SS):**
  The IEEE 802.16 entity at SS shall send DREG-REQ message to the serving BS for de-registration. Action code included in DREG-REQ message corresponds to the Action Code in C-NEM-REQ primitive. If NCMS at BS receives this primitive, it shall respond to it with C-NEM-RSP primitive after deregistration process.

- **NCMS(BS) to IEEE 802.16 entity (BS):**
  The IEEE 802.16 entity at BS shall send DREG-CMD message to the SS for de-registration. Action code included in DREG-CMD message corresponds to the Action Code in C-NEM-REQ primitive. If NCMS at SS receives this primitive, it shall respond to it with C-NEM-RSP primitive after deregistration process.

### 14.2.7.2 C-NEM-RSP

This primitive is used by the NCMS or the IEEE 802.16 entity in response to ranging or registration request in network entry procedures. The Action_Type included in this primitive defines the type of network entry procedures to be performed. The possible Action_Type for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ranging</td>
<td>Ranging procedures between IEEE 802.16 entity and NCMS</td>
</tr>
<tr>
<td>SS Basic Capability</td>
<td>SS Basic Capability negotiation procedures between IEEE 802.16 entity and NCMS</td>
</tr>
<tr>
<td>Registration</td>
<td>Registration procedures between IEEE 802.16 entity and NCMS</td>
</tr>
<tr>
<td>Deregistration</td>
<td>Deregistration procedures between IEEE 802.16 entity and NCMS</td>
</tr>
</tbody>
</table>
14.2.7.2.1 C-NEM-RSP (Action_Type = Ranging)

14.2.7.2.1.1 BS side

14.2.7.2.1.1.1 Function

This primitive returns the result of ranging request.

14.2.7.2.1.1.2 Semantics:

C-NEM-RSP

( Operation_Type: Action,
  Action_Type: Ranging,
  Destination: BS,
  Attribute_List:
    SS Address,
    Result Code,
    Resource Retain Flag,
    HO Process Optimization
)

SS Address
MAC Address of SS that requests ranging

Result Code
Result of ranging request; value range:
  Failed,
  Succeed

Resource Retain Flag
Indicates whether the serving BS will retain or delete the connection information of the SS during HO

HO Process Optimization
Network re-entry process optimization after handover

14.2.7.2.1.1.3 When generated

This primitive is generated when decided to notify the ranging result after receiving ranging request.

14.2.7.2.1.1.4 Effect of receipt

MAC layer sends RNG-RSP message.

14.2.7.2.1.2 SS side

14.2.7.2.1.2.1 Function

This primitive notifies the result of ranging to upper layer entity.

14.2.7.2.1.2.2 Semantics:

C-NEM-RSP

( Operation_Type: Action,
Action_Type: Ranging,
Destination: NCMS,
Attribute_List:
   SS Address,
   Result Code,
   Resource Retain Flag,
   HO Process Optimization

SS Address
   MAC Address of SS that requests ranging

Result Code
   Result of ranging request; value range:
      Failed,
      Succeed

Resource Retain Flag
   Indicates whether the serving BS will retain or delete the connection information of the SS during HO

HO Process Optimization
   Network re-entry process optimization after handover

14.2.7.2.1.2.3 When generated

This primitive is generated when MAC layer receives RNG-RSP message.

14.2.7.2.1.2.4 Effect of receipt

The upper layer entity receives the result of ranging.

14.2.7.2.2 C-NEM-RSP (Action_Type = SS Basic Capability)

14.2.7.2.2.1 Function

This primitive is returned by the result of SS Basic Capability request.

14.2.7.2.2.2 Semantics:

C-NEM-RSP
   ( Operation_Type: Action,
     Action_Type: SS Basic Capability,
     Destination: BS or NCMS,
     Attribute_List:
         SS MAC Address,
         Authorization Policy,
         NSP List,
         NSP Change Count )

SS MAC Address
   48-bit MAC Address which identifies SS.

Authorization Policy
Enumerated type which indicates authorization policy used by SS and BS. The value can be assigned to No Authorization, Only EAP-based authorization, Only RSA-based authorization, EAP-based authorization after RSA-based authorization.

**NSP List**
One or more 24-bit Network Service Provider Identifiers.

**NSP Change Count**
1-Byte NSP Change Count which indicates a change of the NSP list. It will be increased by one (modulo 256) whenever the NSP list changes.

### 14.2.7.2.2.3 When generated

- **NCMS(BS) to IEEE 802.16 entity (BS):**
  This primitive is generated to respond to C-NEM-REQ(SS Basic Capability) from BS.
- **IEEE 802.16 entity (SS) to NCMS(SS):**
  This primitive is generated by the SS when the SS receives SBC-RSP MAC message.

### 14.2.7.2.2.4 Effect of receipt

- **NCMS(BS) to IEEE 802.16 entity (BS):**
  The IEEE 802.16 entity (BS) sends a SBC-RSP message to SS.
- **IEEE 802.16 entity (SS) to NCMS(SS):**
  The NCMS(SS) receives SS basic capability results.

### 14.2.7.2.3 C-NEM-RSP (Action_Type = Registration)

#### 14.2.7.2.3.1 BS side

#### 14.2.7.2.3.1.1 Function

This primitive returns the result of registration request.

#### 14.2.7.2.3.1.2 Semantics:

**C-NEM-RSP**

```
(  Operation_Type: Action,  
  Action_Type: Registration,  
  Destination: BS,  
  Attribute_List:  
    IP management mode,  
    IP Version,  
    Method of Allocating IP Address,  
    Skip IP Address Acquisition  
)
```

**IP Management Mode**

The IP management mode parameter dictates whether the provider intends to manage the SS on an ongoing basis via IP-based mechanisms; value range:

- Unmanaged mode
- IP-managed mode

**IP Version**

IP version; value range:

- IPv4
- IPv6
Method of Allocating IP Address
IP Address Configuration method; value range:
  DHCPv4,
  Mobile IPv4,
  DHCPv6,
  Mobile IPv6,
  IPv6 stateless address auto configuration
Skip IP Address Acquisition
This indicates to an SS whether it should reacquire its IP address on the secondary management connection and related context or reuse its prior context; value range:
  No IP address change,
  Re-acquire IP address

14.2.7.2.3.1.3 When generated
This primitive is generated to notify the result of registration after C-NEM-REQ(Registration) is received at the BS.

14.2.7.2.3.1.4 Effect of receipt
MAC layer sends REG-RSP message.

14.2.7.2.3.2 SS side

14.2.7.2.3.2.1 Function
This primitive notifies the registration result from C-NEM-RSP to upper layer entity

14.2.7.2.3.2.2 Semantics:

C-NEM-RSP
  (Operation_Type: Action,
   Action_Type: Registration,
   Destination: NCMS,
   Attribute_List:
     IP management mode,
     IP Version,
     Method of Allocating IP Address,
     Skip Address Acquisition
  )

IP Management Mode
The IP management mode parameter dictates whether the provider intends to manage the SS on an ongoing basis via IP-based mechanisms; value range:
  Unmanaged mode,
  IP-managed mode
IP Version
IP version; value range:
  IPv4,
  IPv6
Method of Allocating IP Address
IP Address Configuration method; value range:
DHCPv4, Mobile IPv4, DHCPv6, Mobile IPv6, IPv6 stateless address auto configuration

Skip IP Address Acquisition
This indicates to an SS whether it should reacquire its IP address on the secondary management connection and related context or reuse its prior context; value range:
No IP address change, Re-acquire IP address

14.2.7.2.3.2.3 When generated

This primitive is generated when REG-RSP is received by the SS

14.2.7.2.3.2.4 Effect of receipt

Registration result is notified to the upper layer entity

14.2.7.2.4 C-NEM-RSP (Action_Type = Deregistration)

14.2.7.2.4.1 Function

This primitive is generated by the IEEE 802.16 entity (SS) or NCMS to respond to C-NEM-REQ(Deregistration). It is also generated by the IEEE 802.16 entity (BS) or NCMS to respond to C-NEM-REQ(Deregistration).

14.2.7.2.4.2 Semantics:

C-NEM-RSP
( Operation_Type: Action,
  Action_Type: Deregistration,
  Destination: SS, BS or NCMS,
  Attribute_List:
    SS MAC Address,
    Action Code )

SS MAC Address
48-bit MAC Address which identifies SS.

Action Code
Indication of deregistration type.

14.2.7.2.4.3 When generated

— NCMS(BS) to IEEE 802.16 entity (BS):
  This primitive is generated when the IEEE 802.16 entity (BS) receives C-NEM-REQ(Deregistration).
— IEEE 802.16 entity (SS) to NCMS(SS):
  This primitive is generated to by the SS receives DREG-CMD.
— NCMS(SS) to IEEE 802.16 entity (SS):
This primitive is generated when the IEEE 802.16 entity (MS) receives C-NEM-REQ(Deregistration).
— IEEE 802.16 entity (BS) to NCMS(BS):
  This primitive is generated to by the BS receives DREG-REQ.

14.2.7.2.4.4 Effect of receipt

— NCMS(BS) to IEEE 802.16 entity (BS):
  The BS shall send DREG-CMD message to the SS.
— IEEE 802.16 entity (SS) to NCMS(SS):
  The NCMS(SS) completes deregistration procedure.
— NCMS(SS) to IEEE 802.16 entity (SS):
  The MS shall send DREG-REQ message to the BS.
— IEEE 802.16 entity (BS) to NCMS(BS):
  The NCMS(SS) completes deregistration procedure.

14.2.7.3 C-NEM-IND (Event_Type = NBR_BS_Update)

14.2.7.3.1 Function

This primitive is generated by the MS to notify the NCMS about the reception of a neighbor advertisement (MOB_NBR-ADV) message from the serving BS.

14.2.7.3.2 Semantics:

C-NEM-IND

(  
  Event_Type: NBR_BS_Update,  
  Destination: NCMS,  
  Attribute_list:  
    Operator ID,  
    N_Neighbors,  
    Neighbor BSID,  
    HO Process Optimization,  
    DCD/UCD information
)

Operator ID
  Identifier of the network provider

N_Neighbors
  The count of the unique combination of Neighbor BSID, HO Process Optimization and DCD/UCD information

Neighbor BSID
  Base Station ID

HO Process Optimization
  Network re-entry process optimization after handover; bitmap:
  Bit 0: Omit SBC-REQ/RSP management messages during re-entry processing
  Bit 1: Omit PKM Authentication phase except TEK phase during re-entry processing
  Bit 2: Omit PKM TEK creation phase during re-entry processing
  Bit 3: Omit REG-REQ/RSP management messages during re-entry processing
  Bit 4: Omit Network Address Acquisition management messages during re-entry processing
  Bit 5: Omit Time of Day Acquisition management messages during re-entry processing
  Bit 6: Omit TFTP management messages during re-entry processing
Bit 7: MS state information (see 11.14).

14.2.7.3.3 When generated

This primitive is generated by the MS to notify the NCMS of MOB_NBR-ADV contents received from the Serving BS.

14.2.7.3.4 Effect of receipt

Upper layer entity acquires information of neighboring BSs.

14.2.7.4 C-NEM-IND (Event_Type = network attached)

14.2.7.4.1 Function

This primitive is used by SS to inform NCMS(SS) of the completion of initialization procedure which includes synchronization with the BS and acquirement of downlink/uplink transmission parameters.

14.2.7.4.2 Semantics of the service primitive:

\[
\text{C-NEM-IND} \\
\quad ( \text{Event_Type (network attached), Destination (NCMS), Attribute_list: BSID} ) \\
\]

\textbf{BSID} \\
Unique identifier of BS

14.2.7.4.3 When generated

This primitive is generated when the SS completes initialization steps and is ready to perform initial ranging.

14.2.7.4.4 Effect of receipt

NCMS can issue C-NEM-REQ (ranging) to request the SS to perform initial ranging after it receives this primitive.

14.2.8 Subscriber Station Management

The Subscriber Station Management Primitives are a set of primitives to manage the status of subscriber station. A management entity in the NCMS can change the status of mobile terminal into power on/down etc. Those primitives are also used to notify the NCMS of information or events which are related with the status of the mobile terminal.
Figure 373—M-SSM primitives flow for Reset / Power On / Power Down at SS side

Figure 374—M-SSM primitives flow for Reset
Figure 375—M-SSM primitives flow for Hold and Normal resumption

Figure 376—M-SSM primitives flow for Hold and Reset
14.2.8.1 M-SSM-REQ

This primitive is used by NCMS or IEEE 802.16 entity to request status change of the MS. The Action_Type included in this primitive defines the type of status change to be performed. The possible Action_Type for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Action type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power Down</td>
<td>Power down procedure between MS and NCMS</td>
</tr>
<tr>
<td>Reset</td>
<td>Reset procedure</td>
</tr>
<tr>
<td>Hold</td>
<td>Change of the current status to the hold status</td>
</tr>
<tr>
<td>Normal</td>
<td>Change of the current status to the normal status</td>
</tr>
</tbody>
</table>

14.2.8.1.1 M-SSM-REQ (Action_Type = Power On)

14.2.8.1.1.1 Function

This primitive is used by the NCMS to change the status of the SS to Power On. This primitive is only used by the NCMS at SS side.

14.2.8.1.1.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

( Operation_Type: Action,
  Action_Type: Power On,
  Destination: SS,
  Attribute_List:
)

14.2.8.1.1.3 When generated

This primitive is generated when a higher layer entity in NCMS wants to request the IEEE 802.16 entity (SS) to power itself on.

14.2.8.1.1.4 Effect of receipt

The IEEE 802.16 entity at the SS performs power on procedure and responds with the M-SSM-RSP primitive.

14.2.8.1.2 M-SSM-REQ (Action_Type = Power Down)

14.2.8.1.2.1 Function

This primitive is used by NCMS to change the status of SS to Power Down. This primitive is only used by NCMS at SS side.
14.2.8.1.2.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

   (Operation_Type: Action,
    Action_Type: Power Down,
    Destination: SS)

14.2.8.1.2.3 When generated

This primitive is generated when a higher layer entity in NCMS wants to request the IEEE 802.16 entity (SS) to power down.

14.2.8.1.2.4 Effect of receipt

The IEEE 802.16 entity in SS performs power down procedure

14.2.8.1.3 M-SSM-REQ (Action_Type = Reset)

14.2.8.1.3.1 Function

This primitive is used by NCMS at SS or BS to reset the SS.

14.2.8.1.3.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

   (Operation_Type: Action,
    Action_Type: Reset,
    Destination: SS or BS,
    Attribute_list:
      SS MAC Address,
      Reset Code
    )

SS MAC Address
SS Identifier
Reset Code
Reason for reset

14.2.8.1.3.3 When generated

This primitive is generated when a higher layer entity in NCMS wants to reset the SS.

14.2.8.1.3.4 Effect of receipt

If the IEEE 802.16 entity (SS) receives this primitive, it shall respond to the request with M-SSM-RSP primitive and shall re-initialize its MAC. After reset procedure is completed, the IEEE 802.16 SS entity shall notify the NCMS of the completion of reset procedure using M-SSM-IND (Reset) primitive. If the IEEE
IEEE Std 802.16-2009

14.2.8.1.4 M-SSM-REQ (Action_Type = Hold)

14.2.8.1.4.1 Function

This primitive is used by NCMS at BS to change the status of the SS from Normal to Hold status. This primitive is used only by the NCMS at BS side.

14.2.8.1.4.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

( Operation_Type: Action,
  Action_Type: Hold,
  Destination: BS,
  Attribute_list:
    SS MAC Address,
)

SS MAC Address
  SS Identifier

14.2.8.1.4.3 When generated

This primitive is generated when NCMS at BS side wants to change the status of the SS from Normal to Hold status.

14.2.8.1.4.4 Effect of receipt

The BS sends DREG-CMD message with action code = 0x01 to the SS and responds to the request with M-SSM-RSP (Hold) primitive.

14.2.8.1.5 M-SSM-REQ (Action_Type = Normal)

14.2.8.1.5.1 Function

This primitive is used by NCMS at BS to change the status of the SS to Normal status. This primitive is used only by the NCMS at BS side.

14.2.8.1.5.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

( Operation_Type: Action,
  Action_Type: Normal,
  Destination: BS,
  Attribute_list:
    SS MAC Address,
14.2.8.1.5.3 When generated

This primitive is generated when NCMS at BS side wants to change the status of the SS from Hold to Normal status.

14.2.8.1.5.4 Effect of receipt

The BS sends DREG-CMD message with action code = 0x03 to the SS and responds to the request with M-SSM-RSP (Normal) primitive.

14.2.8.2 M-SSM-RSP

This primitive is used by an IEEE 802.16 entity or NCMS to respond to a subscriber station management request. The Action type included in this primitive defines the type of management procedure to be performed. The possible Action Types for this primitive are listed in the table below:

<table>
<thead>
<tr>
<th>Action type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power On</td>
<td>Power on procedure between SS and NCMS</td>
</tr>
<tr>
<td>Power Down</td>
<td>Power down procedure between SS and NCMS</td>
</tr>
<tr>
<td>Reset</td>
<td>Reset procedure</td>
</tr>
<tr>
<td>Hold</td>
<td>Change of the current status to the hold status</td>
</tr>
<tr>
<td>Normal</td>
<td>Change of the current status to the normal status</td>
</tr>
</tbody>
</table>

14.2.8.2.1 M-SSM- RSP (Action_Type = Power On)

14.2.8.2.1.1 Function

This primitive is generated by the IEEE 802.16 entity to respond to M-SSM-REQ (Power On). This primitive is only used by NCMS at SS side.

14.2.8.2.1.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-RSP

```
( Operation_Type: Action,
  Action_Type: Power On,
  Destination: NCMS,
  Attribute_list:
    Result Code
  )
```
14.2.8.2.1.3 When generated

This primitive is generated when the IEEE 802.16 entity (SS) receives M-SSM-REQ (Power On) primitive from NCMS.

14.2.8.2.1.4 Effect of receipt

NCMS completes power-on procedure.

14.2.8.2.2 M-SSM-RSP (Action_Type = Power Down)

14.2.8.2.2.1 Function

This primitive is generated by the IEEE 802.16 entity to respond to M-SSM-REQ (Power Down). This primitive is only used by NCMS at SS side.

14.2.8.2.2.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-RSP

( Operation_Type: Action,
  Action_Type: Power Down,
  Destination: NCMS,
  Attribute_list:
    Result Code )

14.2.8.2.2.3 When generated

This primitive is generated when the IEEE 802.16 entity (SS) receives M-SSM-REQ (Power Down) primitive from NCMS.

14.2.8.2.2.4 Effect of receipt

NCMS completes power-down procedure.

14.2.8.2.3 M-SSM- RSP (Action_Type = Reset)

14.2.8.2.3.1 Function

This primitive is generated by the IEEE 802.16 entity to respond to M-SSM-REQ (Reset).

14.2.8.2.3.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-RSP

( Operation_Type: Action,
  Action_Type: Reset,
  Destination: NCMS,
  Attribute_list: }
14.2.8.2.3.3 When generated

This primitive is generated when the IEEE 802.16 entity (SS) receives M-SSM-REQ (Reset) primitive from NCMS.

14.2.8.2.3.4 Effect of receipt

NCMS completes reset procedure.

14.2.8.2.4 M-SSM-RSP (Action_Type = Hold)

14.2.8.2.4.1 Function

This primitive is used by BS to respond to M-SSM-REQ (Hold) primitive. This primitive is used only by the BS.

14.2.8.2.4.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-RSP

( Operation_Type: Action,
  Action_Type: Hold,
  Destination: NCMS,
  Attribute_list:
    SS MAC Address,
  SS Identifier
)

14.2.8.2.4.3 When generated

This primitive is generated when the BS receives M-SSM-REQ (Hold) primitive form the NCMS and sends DREG-CMD message with action code = 0x01 to the SS.

14.2.8.2.4.4 Effect of receipt

The NCMS recognizes that the status of the SS has been changed to Hold status.

14.2.8.2.5 M-SSM-RSP (Action_Type = Normal)

14.2.8.2.5.1 Function

This primitive is used by BS to respond to M-SSM-REQ (Normal) primitive. This primitive is used only by the BS.
14.2.8.2.5.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-REQ

( Operation_Type: Action,
  Action_Type: Normal,
  Destination: NCMS,
  Attribute_list:
    SS MAC Address,
)

SS MAC Address
SS Identifier

14.2.8.2.5.3 When generated

This primitive is generated when the BS receives M-SSM-REQ (Normal) primitive form the NCMS and sends DREG-CMD message with action code = 0x03 to the SS.

14.2.8.2.5.4 Effect of receipt

The NCMS recognizes that the status of the SS has changed to Normal status.

14.2.8.3 M-SSM-IND

This primitive is used by the IEEE 802.16 entity at SS to notify NCMS of some events. The possible event types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset</td>
<td>Notification of reset event</td>
</tr>
<tr>
<td>Hold</td>
<td>Notification of status change to Hold status</td>
</tr>
<tr>
<td>Normal</td>
<td>Notification of status change to Normal status</td>
</tr>
</tbody>
</table>

14.2.8.3.1 M-SSM-IND (Event_Type = Reset)

14.2.8.3.1.1 Function

This primitive is generated by the IEEE 802.16 entity (SS) to notify the NCMS at SS side of a reset event. This primitive is used only by the SS.

14.2.8.3.1.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-IND

( Event_Type: Reset,
  Destination: NCMS,)
14.2.8.3.1.3 When generated

This primitive is generated when the IEEE 802.16 entity at SS receives RES-CMD message from the BS. The IEEE 802.16 entity issues this primitive after internal reset procedure.

14.2.8.3.1.4 Effect of receipt

NCMS performs internal reset procedure and initialization of the IEEE 802.16 entity.

14.2.8.3.2 M-SSM-IND (Event_Type = Hold)

14.2.8.3.2.1 Function

This primitive is generated by the IEEE 802.16 entity (SS) to notify the NCMS at SS side of a hold event. This primitive is used only by the SS.

14.2.8.3.2.2 Semantics of the service primitive:

The following parameters are included in this primitive.

```
M-SSM-IND
  (  
    Event_Type: Hold,
    Destination: NCMS,
    Attribute_list:
      SS MAC Address
  )
```

14.2.8.3.2.3 When generated

This primitive is generated when the IEEE 802.16 entity at SS receives DREG-CMD message with action code = 0x01 from the BS.

14.2.8.3.2.4 Effect of receipt

NCMS waits for the next M-SSM-IND primitive with Action_Type = Normal or Reset.

14.2.8.3.3 M-SSM-IND (Event_Type = Normal)

14.2.8.3.3.1 Function

This primitive is generated by the IEEE 802.16 entity (SS) to notify the NCMS at SS side of a normal event. This primitive is used only by the SS.
14.2.8.3.3.2 Semantics of the service primitive:

The following parameters are included in this primitive.

M-SSM-IND

(  
  Event_Type: Normal,  
  Destination: NCMS,  
  Attribute_list:  
    SS MAC Address  
)

14.2.8.3.3.3 When generated

This primitive is generated when the IEEE 802.16 entity at SS receives DREG-CMD message with action code = 0x03 from the BS. The IEEE 802.16 entity issues this primitive after it changes its status to Normal status.

14.2.8.3.3.4 Effect of receipt

NCMS returns back to the normal status.

14.2.9 QoS management

The Service Flow Management Primitives are a set of primitives for supporting QoS management between SS or BS and the Service Flow Management Service on the NCMS. They are defined to support QoS service flows. A service flow ID for a unidirectional service flow is created and managed by the NCMS (or a network entity). The (MS MAC address, Service Flow ID) pair uniquely identifies a service flow. The CID is only managed by the MAC layer in a BS. The MS MAC Address in C-SFM-REQ is used to authorize the MS whether the QoS information is permitted.

Service flow application clients that interact with the CS convergence layer should transform service flow information and CS parameter information to the appropriate parameters of the network protocol in the network side and in the reverse direction. How to convert specific QoS parameters between an IEEE 802.16-Service-Flow and the Network or Packet Data Flows is out of scope. The service flow management primitives are designed as a 2-way handshake because the resource reservation protocols in IETF and the primitives at the IEEE 802.16 MAC SAP are designed as a 2-way handshake, but service flow MAC management messages in this standard are designed as a 3-way handshake (DSx-REQ/RSP/ACK) in order to negotiate QoS requirements for a given service flow.
Figure 377—SFM-REQ(Create/Set) and C-SFM-RSP(Create/Set) flow, IEEE 802.16 entity initiated
Figure 378—C-SFM-REQ (create and Set) and C-SFM-RSP (Create and Set) primitives flow, NCMS initiated

Figure 379—C-SFM-REQ(Delete) and C-SFM-RSP(Delete) primitives flow, IEEE 802.16 entity initiated
14.2.9.1 C-SFM-REQ

This primitive is used by an IEEE 802.16 entity or NCMS to trigger a service flow management procedure. The Operation_Type included in this primitive defines the type of service flow management procedure to be performed. The possible Operation_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Operation_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create</td>
<td>Create a new service flow</td>
</tr>
<tr>
<td>Set</td>
<td>Change parameters of existing service flow</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletion of an existing service flow</td>
</tr>
</tbody>
</table>

The following subclauses define the primitive when its operation type is set to a specific operation.
14.2.9.1.1 C-SFM-REQ (Operation_Type = Create)

14.2.9.1.1 Function

When Operation_Type is set to Create, this primitive shall be used to initiate a new service flow creation by either an IEEE 802.16 entity or NCMS. This primitive shall contain QoS information for the new service flow.

14.2.9.1.1.2 Semantics of the service primitive:

The parameters of the primitives are as follows:

C-SFM-REQ

(  
  Operation_Type: Create,
  Destination: MS, or BS, or NCMS,
  Attribute_List:
    MS MAC Address,
    Service flow ID,
    Service flow descriptor,
    Service flow information,
    CS parameter information

)

MS MAC Address
48-bit unique identifier used by MS. MS MAC Address is used for user authorization

Service flow ID
Unique identifier to identify a unidirectional service flow, included in the primitive for NCMS initiated service flow creation.

Service flow descriptor
Information regarding the attribute an uplink or downlink service flow

Service flow information
Required QoS information of a service flow include traffic characteristics and a scheduling type such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency. In case of MBS flow creation originated by NCMS, the service flow information shall additionally contain MBS_Zone, the connection identifier CID, Logical Channel ID and security association.

CS parameter information
Required CS information for classification and handling of the service flow.

14.2.9.1.1.3 When generated

— IEEE 802.16 entity to NCMS:
  This primitive is generated when the IEEE 802.16 entity creates a service flow (i.e., a BS receives a DSA-REQ message.).
— NCMS to IEEE 802.16 entity:
  This primitive is used when the QoS management entity in the NCMS triggers the creation of a new service flow.

14.2.9.1.1.4 Effect of receipt

— IEEE 802.16 entity to NCMS:
The QoS management entity in the NCMS shall respond to this primitive using C-SFM-RSP(Create). The management entity for service flows checks the validity of the request from the point of view of its own resources. If the request is accepted, the QoS management entity in NCMS creates unique service flow ID for the request.

— NCMS to IEEE 802.16 entity:
The IEEE 802.16 entity receiving the primitive shall trigger the transmission of a DSA-REQ message following the information provided by this primitive.

14.2.9.1.2 C-SFM-REQ (Operation_Type = Set)

14.2.9.1.2.1 Function

When Operation_Type is set to Set, this primitive shall be used to modify existing service flow parameters by either an IEEE 802.16 entity or NCMS. This primitive shall contain the new information for the modifications of the service flow.

14.2.9.1.2.2 Semantics of the service primitive:

The parameters of the primitive are as follows:

C-SFM-REQ

( Operation_Type: Set,
  Destination: MS, or BS, or NCMS,
  Attribute_List:
    Service flow ID,
    MS MAC Address,
    Service flow descriptor,
    Service flow information,
    CS parameter information )

Service flow ID
Unique identifier to identify a service flow.

MS MAC Address
48-bit unique identifier used by MS. MS MAC Address is used for user authorization

Service flow descriptor
Information regarding the attribute of an uplink or downlink service flow

Service flow information
Required QoS information of a service flow include traffic characteristics and a scheduling type such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency. In case of MBS flow set originated by NCMS, the service flow information shall additionally contain MBS_Zone, the connection identifier CID, Logical Channel ID and security association.

CS parameter information
Required IP filter rules of a service flow such as packet classification rule and IPv6 flow label

14.2.9.1.2.3 When generated

— IEEE 802.16 entity to NCMS:
  This primitive is generated when the IEEE 802.16 entity change the parameters of an existing service flow (BS receives a DSC-REQ message).
— NCMS to IEEE 802.16 entity:
This primitive is generated when the QoS management entity in NCMS informs the IEEE 802.16 entity of the QoS information modification.

14.2.9.1.2.4 Effect of receipt

— IEEE 802.16 entity to NCMS:
The QoS management entity in the NCMS shall respond to this primitive by sending C-SFM-RSP(Set). The management entity for service flows checks the validity of the request from the point of view of its own resources.

— NCMS to IEEE 802.16 entity:
The IEEE 802.16 entity receiving the primitive shall trigger transmission of a DSC-REQ message following the information provided by this primitive.

14.2.9.1.3 C-SFM-REQ (Operation_Type = Delete)

14.2.9.1.3.1 Function

When Operation_Type is set to Delete, this primitive shall be used to delete an existing service flow by either an IEEE 802.16 entity or NCMS.

14.2.9.1.3.2 Semantics of the service primitive:

The parameters of the primitive are as follows:

```
C-SFM-REQ
(  
  Operation_Type: Delete,  
  Destination: MS, or BS, or NCMS,  
  Attribute_List:  
    Service flow ID  
)
```

Service flow ID
Unique identifier to identify a service flow.

14.2.9.1.3.3 When generated

— IEEE 802.16 entity to NCMS:
This primitive is generated when the IEEE 802.16 entity delete an existing service flow (BS receives a DSD-REQ message).

In the MBS case, this primitive only can be issued from NCMS to IEEE 802.16 entity.

— NCMS to IEEE 802.16 entity:
This primitive is generated when the QoS management entity in NCMS informs the IEEE 802.16 entity of the deletion of an existing service flow.

14.2.9.1.3.4 Effect of receipt

— IEEE 802.16 entity to NCMS:
The QoS management entity in NCMS shall respond to this primitive by sending C-SFM-RSP(Delete). The management entity for service flows release assigned resources for the service flow ID.

— NCMS to IEEE 802.16 entity:
The IEEE 802.16 entity receiving the primitive shall transmit the DSD-REQ message including the information provided by this primitive.
14.2.9.2 C-SFM-RSP

This primitive is used by an IEEE 802.16 entity or NCMS to respond to the request to begin a service flow management procedure. The Operation_Type included in this primitive defines the type of service flow management procedure to be performed. The possible Operation_Types for this primitive are listed in table below:

<table>
<thead>
<tr>
<th>Operation_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create</td>
<td>Create a new service flow</td>
</tr>
<tr>
<td>Set</td>
<td>Change parameters of existing service flow</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletion of an existing service flow</td>
</tr>
</tbody>
</table>

The following subclauses define the primitive when its operation type is set to a specific operation.

14.2.9.2.1 C-SFM-RSP (Operation_Type = Create)

14.2.9.2.1.1 Function

This primitive is used by the IEEE 802.16 entity or the QoS management entity in NCMS to respond to the C-SFM-REQ for a service flow creation. Service flow information in this primitive contains approved QoS information if the request is accepted.

14.2.9.2.1.2 Semantics of the service primitive:

The parameters of the primitives are as follows:

```
C-SFM-RSP
(
    Operation_Type: Create,
    Destination: MS, or BS, or NCMS,
    Attribute_List:
        MS MAC Address,
        Service flow ID,
        Service flow descriptor,
        Service flow information,
        CS parameter information,
        Service flow error parameter information
)
```

**MS MAC Address**

48-bit unique identifier used by MS. MS MAC Address is used for user identification

**Service flow ID**

Unique identifier to identify a service flow

**Service flow descriptor**

Information regarding the attribute an uplink or downlink service flow

**Service flow information**

Approved complete QoS information of a service flow such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency, target Packet Error Rate. In case of MBS flow creation originated by
NCMS, the service flow information shall additionally contain MBS_Zone, the connection identifier CID, Logical Channel ID and security association.

**CS parameter information**
Approved packet filter rules of a service flow such as packet classification rule and IPv6 flow label

**Service flow error parameter information**
Failed reason and every specific failed QoS parameter if a C-SFM-REQ is rejected

### 14.2.9.2.1.3 When generated

- IEEE 802.16 entity to NCMS:
  This primitive is generated when an IEEE 802.16 entity receives a DSA-RSP message.
- NCMS to IEEE 802.16 entity:
  This primitive is generated when the QoS management entity in NCMS responds to C-SFM-REQ(Create) primitive.

### 14.2.9.2.1.4 Effect of receipt

- IEEE 802.16 entity to NCMS:
  This primitive informs the result of the service flow creation to the QoS management entity in NCMS.
- NCMS to IEEE 802.16 entity:
  This primitive informs the result of the service flow creation to an IEEE 802.16 entity. An IEEE 802.16 entity receiving the primitive shall transmit DSA-RSP message based on the information provided by this primitive.

### 14.2.9.2.2 C-SFM-RSP (Operation_Type = Set)

#### 14.2.9.2.2.1 Function

This primitive is used by the IEEE 802.16 entity or the QoS management entity in NCMS to respond to the C-SFM-REQ(Set) for a change in an existing service flow. Service flow information in this primitive contains approved QoS information if the request is accepted.

#### 14.2.9.2.2.2 Semantics of the service primitive:

The parameters of the primitives are as follows:

**C-SFM-RSP**

(  
  Operation_Type: Set,  
  Destination: MS, or BS, or NCMS,  
  Attribute_List:  
    Service flow ID,  
    Service flow information,  
    CS parameter information,  
    Service flow error parameter information  
)

**Service flow ID**
Unique identifier to identify a service flow

**Service flow information**
Approved complete QoS information of a service flow such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved
traffic rate, minimum tolerable traffic rate, tolerate jitter and maximum latency. In case of MBS
flow set originated by NCMS, the service flow information shall additionally contain
MBS_Zone, the connection identifier CID, Logical Channel ID and security association.

CS parameter information
Approved IP filter rules of a service flow such as packet classification rule and IPv6 flow label

Service flow error parameter information
Failed reason and every specific failed QoS parameter if the request is rejected

14.2.9.2.2.2.3 When generated

— IEEE 802.16 entity to NCMS:
This primitive is generated when an IEEE 802.16 entity receives a DSC-RSP message.
— NCMS to IEEE 802.16 entity:
This primitive is generated when the QoS management entity in NCMS responds to C-SFM-
RSP(Set) primitive.
In the MBS case, this primitive only can be issued from IEEE 802.16 entity to NCMS.

14.2.9.2.2.4 Effect of receipt

— IEEE 802.16 entity to NCMS:
This primitive informs the result of the service flow modification to the QoS management entity in
NCMS.
— NCMS to IEEE 802.16 entity:
This primitive informs the result of the service flow modification to an IEEE 802.16 entity. An IEEE
802.16 entity receiving the primitive shall transmit DSC-RSP message based on the information
provided by this primitive.

14.2.9.2.3 C-SFM-RSP(Operation_Type = Delete)

14.2.9.2.3.1 Function
This primitive is used by the IEEE 802.16 entity or the QoS management entity in NCMS to respond to the
service flow deletion request.

14.2.9.2.3.2 Semantics of the service primitive:
The parameters of the primitives are as follows:

C-SFM-RSP

( Operation_Type: Delete,
  Destination: MS, or BS, or NCMS,
  Attribute_List:
    Service flow ID
    Service flow error parameter information
  )

Service flow ID
Unique identifier to identify a service flow

Service flow error parameter information
Failed reason if a C-SFM-REQ(Delete) request is rejected
14.2.9.2.3.3 When generated

— IEEE 802.16 entity to NCMS:
  This primitive is generated when an IEEE 802.16 entity receives a DSD-RSP message.
— NCMS to IEEE 802.16 entity:
  This primitive is generated when the QoS management entity in NCMS responds to C-SFM-REQ(Delete) primitive.

14.2.9.2.3.4 Effect of receipt

— IEEE 802.16 entity to NCMS:
  This primitive informs the result of the service flow deletion of the QoS management entity in NCMS. The QoS management entity in NCMS deletes assigned resources for service flow ID.
— NCMS to IEEE 802.16 entity:
  This primitive informs the result of the service flow deletion to an IEEE 802.16 entity. An IEEE 802.16 entity receiving the primitive shall transmit DSD-RSP message based on the information provided by this primitive.

14.2.10 Multicast and Broadcast Service Management

This subclause only applies to Multi-BS MBS.

14.2.10.1 MBS Capability Discovery

![C-MBS-REQ (Get) and C-MBS-RSP (Get) primitives flow](image)
14.2.10.1.1 C-MBS-REQ (Operation_Type = Get)

14.2.10.1.1.1 Function

This primitive is originated by the NCMS to a BS, to discover the MBS capability of the BS.

14.2.10.1.1.2 Semantics of this primitive

C-MBS-REQ

(  
  Operation_Type: Get,  
  Destination: BS,  
)

14.2.10.1.1.3 When generated

NCMS sends this primitive to a BS to discover its MBS capability.

14.2.10.1.1.4 Effect of receipt

Upon receiving this primitive, BS shall return the MBS capability in the C-MBS-RSP message.

14.2.10.1.2 C-MBS-RSP (Operation_Type = Get)

14.2.10.1.2.1 Function

This primitive is sent by a BS to the NCMS in response to a C-MBS-REQ (Get). The primitive includes the information about the MBS capability of the BS.

14.2.10.1.2.2 Semantics of this primitive

The parameters of the primitive are as follows:

C-MBS-RSP

(  
  Operation_Type: Get,  
  Destination: NCMS,  
  Attribute_List:  
    MBS Capability Information  
)

MBS Capability Information

Type of MBS capability:

Bit 0: Type1, simple MBS capability, no macro diversity,
Bit 1: Type2, full MBS capability, macro diversity

14.2.10.1.2.3 When generated

BS returns this primitive, in response to the C-MBS-RSP message from NCMS.

14.2.10.1.2.4 Effect of receipt

NCMS gets confirmation that BS’s MBS capability has been configured.
14.2.10.2 MBS Configuration Management Setting

**14.2.10.2.1 C-MBS-REQ (Operation_Type = Set)**

**14.2.10.2.1.1 Function**

This primitive is send by the NCMS to a BS, to configure the MBS information of the BS.

**14.2.10.2.1.2 Semantics of this primitive**

```
C-MBS-REQ
    (  
        Operation_Type: Set,  
        Destination: BS,  
        Attribute_List:  
            MBS_Zone,  
            MBS_Type  
    )
```

**MBS_Zone**

ID of the MBS zone as defined in 6.3.23.2.4. If the ID is 0xFF, it means that the BS does not belong to the MBSZone anymore. If the ID is not same as the value stored in BS, BS should modify according to the new value.

**MBS Type**

Type of MBS mode which shall be used. Two MBS types are defined:

- Type 1 for MBS without macro diversity
- Type 2 for MBS with macro diversity
If the MBS Zone is 0xFF, this parameter is omitted. If the value is not the same as the value stored in BS, BS should update to the new value accordingly.

14.2.10.2.1.3 When generated

NCMS sends this primitive to configure MB’s MBS capability.

14.2.10.2.1.4 Effect of receipt

Upon receiving this primitive, BS shall set its MBS capability according to the attributes included in the primitive.

14.2.10.2.2 C-MBS-RSP (Operation_Type = Set)

14.2.10.2.2.1 Function

This primitive is send by a BS to the NCMS in response to a C-MBS-REQ (Set) primitive.

14.2.10.2.2.2 Semantics of this primitive

C-MBS-RSP

( Operation_Type: Set, Destination: NCMS, Attribute_List: MBS Error parameter information )

MBS Error parameter information

Failed reason

14.2.10.2.2.3 When generated

BS returns this primitive, in response of the C-MBS-RSP message from NCMS.

14.2.10.2.2.4 Effect of receipt

Upon receiving this primitive, BS shall set its MBS capability according to the attributes included in the primitive.
14.2.10.3 MBS Configuration Management Layout

Figure 383—C-MBS-IND (Layout) primitive flow

Figure 384—MBS Service Flow (Create and Delete)
14.2.10.3.1 C-MBS-IND (MBS Portion Layout)

14.2.10.3.1.1 Function

This primitive is originated by the MBS Server and sent to all BS's that belong to the appropriate MBS zone. It is only send if type2 MBS capability is used in the MBS zone. The C-MBS-IND (Layout) primitive is send from the MBS server to the BS's on a per IEEE 802.16 downlink frame basis. The MBS-Portion-Layout primitive may be sent via a broadcast or multicast connection to the IEEE 802.16 entities and is not acknowledged. The BS has to generate a MBS portion as part of the IEEE 802.16 downlink frame according to information elements received by the C-MBS-IND (Layout) primitive. Several sets of information elements define the position size and layout of the MBS portion. The tuple MBS portion symbol/subchannel and offset/size specify the start portion and size of the MBS portion itself. The primitive contains list of burst definitions which specifies the position and size of all bursts inside the MBS portion. Every burst definition contains a list of MAC PDU definitions which specifies all the MAC PDU’s inside a burst. In addition the primitive contains a time reference for synchronization purposes.

14.2.10.3.1.2 Semantics of this primitive

The parameters of this primitive are as follows:

**C-MBS-IND**

(  
  Event_Type: MBS Portion Layout,  
  Destination: BS,  
  Layout Attribute_List:  
    MBS Portion Symbol Offset,  
    MBS Portion Subchannel Offset,  
    MBS Portion Number of Symbols,  
    MBS Portion Number of Subchannels,  
    Time Reference,  
    List of Burst Attributes:  
      (  
        Burst Symbol Offset,  
        Burst Subchannel Offset,  
        Burst No of symbols,  
        Burst No of subchannels,  
        Coding Scheme,  
        List of MAC PDU Attributes:  
          (  
            CID  
            Logical Flow ID,  
            MAC PDU Size  
          )  
      )  
  )  
)

**MBS Portion Symbol Offset**

MBS Portion Symbol Offset defines the start position of the MBS portion inside the downlink frame in number of OFDMA symbols.

**MBS Portion Subchannel Offset**

MBS Portion Subchannel Offset defines the start position of the MBS portion inside the downlink frame in number of OFDMA subchannels.

**MBS Portion No of symbols**

MBS Portion No of symbols defines the size of the MBS portion inside the downlink frame in number of OFDMA symbols.

**MBS Portion No of subchannels**

MBS Portion No of subchannels defines the size of the MBS portion inside the downlink frame in number of OFDMA subchannels.

**Time reference**

The time reference contains the current absolute time in the MBS server plus a static offset. It shall be derived from an absolute time reference. The static offset shall be equal or larger than the longest transport delay between MBS server and BS inside an MBS zone. Based on this time value and its own time reference, BS shall incorporate the MBS portion in the appropriate downlink frame. To incorporate the appropriate upper layer data into the MBS portion, the upper layer packets of MBS data flows shall be time stamped. The assignment of time stamp information to data packets is out of the scope of IEEE Std 802.16g.

**List of Burst Attributes**

The list contains a set of parameters for every burst.

**Burst Symbol Offset**

MBS Portion Symbol Offset defines the start position of a burst inside the MBS portion of a downlink frame in number of OFDMA symbols. The Burst Symbol Offset is defined relative to the position of the MBS portion.

**Burst Subchannel Offset**

MBS Portion Subchannel Offset defines the start position of a burst inside the MBS portion of a downlink frame in number of OFDMA subchannels. The burst subchannel Offset is defined relative to the position of the MBS portion.

**Burst No of symbols**

The burst No of symbols defines the size of the burst inside the MBS portion of a downlink frame in number of OFDMA symbols.

**Burst No of subchannels**

The burst No of subchannels defines the size of the burst inside the MBS portion of a downlink frame in number of OFDMA subchannels.

**Coding Scheme**

This information element defines the coding scheme of the burst.

**List of MAC PDU Attributes**

The list contains a set of parameters for every MAC PDU.

**CID**

This information element defines the CID of the MAC PDU.

**Logical Flow ID**

This information element defines the Logical Flow ID of the MAC PDU.

**MAC PDU size**

This information element defines the size of the MAC PDU in bytes. The order of the MAC PDU’s inside a burst is given by the list order.

**14.2.10.3.1.3 When generated**

NCMS sends this primitive to provide MBS zone layout.

**14.2.10.3.1.4 Effect of receipt**

The BS has to generate a MBS portion as part of the IEEE 802.16 downlink frame according to information elements received by the C-MBS-IND (Layout) primitive.
14.2.10.3.2 C-MBS-REQ

14.2.10.3.2.1 C-MBS-REQ (Operation_Type = Create)

14.2.10.3.2.1.1 Function

This primitive can be sent from NCMS, and is used to notify the BSs which are in one of the MBS zones to create a new MBS transmitted radio link.

14.2.10.3.2.1.2 Semantics of the service primitive:

The parameters of the primitives are as follows:

\[
\text{C-MBS-REQ} \\
( \\
\text{Operation\_Type: Create,} \\
\text{Destination: BS,} \\
\text{Attribute\_List:} \\
\quad \text{MBS Zone,} \\
\quad \text{Service flow ID,} \\
\quad \text{Service flow information,} \\
\quad \text{CS parameter information} \\
)
\]

**MBS Zone**

ID of the MBS zone as defined in 6.3.23.2.4

**Service flow ID**

Unique identifier to identify a unidirectional service flow, included in the primitive for NCMS initiated service flow creation.

**Service flow information**

Required QoS information of a service flow include traffic characteristics and a scheduling type such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency, the connection identifier CID, Logical Channel ID and security association.

**CS parameter information**

Required CS information for classification and handling of the service flow.

14.2.10.3.2.1.3 When generated

This primitive used from NCMS to IEEE 802.16 entities when the new MBS service data need to be delivered.

14.2.10.3.2.1.4 Effect of receipt

The IEEE 802.16 entity receiving the primitive shall trigger transmission of a DSA-REQ messages following the information provided by this primitive.

14.2.10.3.2.2 C-MBS-REQ (Operation_Type = Delete)

14.2.10.3.2.2.1 Function

When Operation_Type is set to 'Delete', this primitive shall be used to initiate an existing MBS radio link deletion by NCMS.
14.2.10.3.2.2 Semantics of the service primitive:

The parameters of the primitive are as follows:

C-MBS-REQ

    (                          
    Operation_Type: Delete,    
    Destination: BS,          
    Attribute_List:           
        MBS Zone             
    )

MBS Zone
    ID of the MBS zone as defined in 6.3.23.2.4.

14.2.10.3.2.3 When generated

This primitive is from NCMS to BS to inform the IEEE 802.16 entities of the deletion of an existing MBS radio link.

14.2.10.3.2.4 Effect of receipt

The IEEE 802.16 entity receiving the primitive shall transmit the DSD-REQ message to release the MBS radio link.

14.2.10.3.3 C-MBS-RSP

14.2.10.3.3.1 C-MBS-RSP (Operation_Type = Create)

14.2.10.3.3.1.1 Function

This primitive is used by the IEEE 802.16 entities to respond to the C-MBS-REQ for a MBS radio link creation. The MBS path information in this primitive contains approved QoS information if the request is accepted.

14.2.10.3.3.1.2 Semantics of the service primitive:

The parameters of the primitives are as follows:

C-MBS-RSP

    (                          
    Operation_Type: Create,    
    Destination: NCMS,         
    Attribute_List:           
        MBS Zone,             
        Service flow ID,      
        Service flow information,   
        CS parameter information, 
        Service flow error parameter information 
    )

MBS Zone
    ID of the MBS zone as defined in 6.3.23.2.4.

Service flow ID
    Unique identifier to identify a service flow
Service flow information
Approved complete QoS information of a service flow such as service class name, QoS parameter set type, maximum sustained traffic rate, maximum traffic burst, minimum reserved traffic rate, minimum tolerable traffic rate, service flow scheduling type, tolerate jitter and maximum latency, target Packet Error Rate, connection identifier CID, Logical Channel ID and security association.

CS parameter information
Approved IP filter rules of a service flow such as packet classification rule and IPv6 flow label.

Service flow error parameter information
Failed reason and every specific failed QoS parameter if the request is rejected.

14.2.10.3.3.1.2.1 When generated
This primitive is generated when an IEEE 802.16 entity receives a C-MBS-REQ (Create) primitive.

14.2.10.3.3.1.3 Effect of receipt
The NCMS receiving the primitive will record the parameters in it.

14.2.10.3.3.2 C-MBS-RSP (Operation_Type = Delete)

14.2.10.3.3.2.1 Function
This primitive is used by the IEEE 802.16 entities to respond to the C-MBS-REQ for a MBS radio link deletion.

14.2.10.3.3.2.2 Semantics of the service primitive:
The parameters of the primitives are as follows:

C-MBS-RSP
(
    Operation_Type: Delete,
    Destination: NCMS,
    Attribute_List:
        MBS Zone,
        BSID,
        Error Reason
)

MBS Zone
ID of the MBS zone as defined in 6.3.23.2.4.

BSID
ID of the BS which is response to the MBS data path deletion

Error Reason
Failed reason if a C-MBS-REQ is rejected

14.2.10.3.3.2.3 When generated
This primitive is generated when an IEEE 802.16 entity receives a C-MBS-REQ (Delete) primitive.

14.2.10.3.3.2.4 Effect of receipt
The NCMS receiving the primitive will know that whether the MBS radio link be deleted.
14.2.11 LBS Management

The NCMS manages the LBS capabilities that are implemented in the BS and the MS. LBS Management sub clause provides a set of primitives for NCMS to retrieve parameters that are required for supporting LBS. Figure 517 depicts the LBS Management primitives.

![Figure 385—LBS Management Primitives](image)

<table>
<thead>
<tr>
<th>Operation_Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get</td>
<td>LBS parameters</td>
</tr>
</tbody>
</table>

14.2.11.1 C-LBS-REQ

NCMS sends C-LBS-REQ primitive.

14.2.11.1.1 Function

This primitive is used by NCMS to request LBS parameters that are needed for estimating the MS location.

14.2.11.1.2 Semantics of the service primitive:

This parameters of the primitive are as follow:
C-LBS-REQ
(  
Operation_Type: Get,  
Destination: BS,  
Attribute_List:  
   MS MAC Address,  
   LBS Parameter Types  
)

MS MAC Address
48-bit MAC address that identifies the MS.

LBS Parameter Types
Identify the types of LBS parameter requested by NCMS. It is a bit field \{CINR, RSSI, D-TDOA, U-TDOA\}. “1” in each bit indicates the corresponding parameter is requested.

14.2.11.1.3 When generated
A trigger from a LBS application (e.g. E911 service) will initiate NCMS to call this primitive.

14.2.11.1.4 Effect of receipt
When this primitive is called, the BS will send C-LBS-ACK to NCMS to acknowledge the receipt of C-LBS-REQ, and then execute the necessary procedure to collect the LBS of parameters.

14.2.11.2 C-LBS-ACK

14.2.11.2.1 Function
This primitive acknowledges that C-LBS-REQ has been received.

14.2.11.2.2 Semantics of the service primitive
This parameters of the primitive are as follow:

C-LBS-ACK
(  
Event_Type: LBS,  
Destination: NCMS,  
Attribute_List:  
   MS MAC Address,  
)

MS MAC Address
48-bit MAC address that identifies the MS.

14.2.11.2.3 When generated
The reception of C-LBS-REQ.

14.2.11.2.4 Effect of receipt
The NCMS advances to the second stage of the 3-way LBS handshake exchange with the BS IEEE 802.16 entity.
14.2.11.3 C-LBS-RSP

14.2.11.3.1 Function

This primitive is used by BS to return LBS parameters as requested in C-LBS-REQ.

14.2.11.3.2 Semantics of the service primitive:

The parameters of the primitive are as follow:

C-LBS-RSP

(  
  Operation_Type: Get,  
  Destination: NCMS,  
  Attribute_List:  
    MS MAC Address,  
    Requested LBS Parameters[]  
      BSID,  
      CINR mean,  
      RSSI mean  
      D-TDOA,  
      U-TDOA  
)

MS MAC Address

48-bit MAC address that identifies the MS.

Requested LBS Parameters[]

Requested LBS Parameters is an array that contains the following parameters:

- BSID—BS unique identifier of serving BS and neighboring BSs, and is used as the index of the array.
- CINR mean—indicates the mean CINR measured by the MS from the serving BS or neighboring BSs as identified in BSID. The value shall be interpreted as a signed byte with units of 0.5 dB.
- RSSI mean—indicates the mean RSSI measured by the MS from the serving BS or neighboring BSs as identified in BSID. The value shall be interpreted as an unsigned byte with units of 0.25 dB, such that 0x00 is interpreted as –103.75 dBm, an MS shall be able to report values in the range –103.75 dBm to –40 dBm.
- D-TDOA—indicates the delay of DL signals that MS received from a neighboring BS, as identified by BSID, relative to the serving BS. The value shall be interpreted as a signed integer in units of micro second.
- U-TDOA—indicates the delay of UL signals that a neighboring BS, as identified by BSID, receives from the MS, relative to the serving BS. The value shall be interpreted as a signed integer in units of nano second.

14.2.11.3.3 When generated

The reception of C-LBS-REQ.

14.2.11.3.4 Effect of receipt

This primitive returns the LBS parameters to NCMS.

(informative)

Supporting material for frequencies below 11 GHz

B.1 Performance characteristics

B.1.1 Reserved

B.1.2 WirelessMAN-OFDM/OFDMA PHY symbol and performance parameters

The effective bandwidth of the transmitted signal is related to the subcarrier spacing and the number of subcarriers.

In order to calculate the sampling frequency for any bandwidth, the bandwidth efficiency is defined as shown in Equation (B.1).

\[ BW_{Efficiency} = \frac{F_s}{BW} \cdot \frac{(N_{used} + 1)}{N_{FFT}} = \frac{\Delta f \cdot (N_{used} + 1)}{BW} \]

(B.1)

where

- \( BW \) is the channel bandwidth (Hz)
- \( F_s \) is the sampling frequency (Hz)
- \( \Delta f \) is the subcarrier spacing (Hz)
- \( N_{used} + 1 \) is the number of active subcarriers used in the FFT (pilot and data subcarriers) + DC subcarrier
- \( N_{FFT} \) is the FFT size

The bandwidth efficiency is designed to be in the range of 83% to 95%, depending mainly on the FFT size, in order to occupy the maximum usable bandwidth but still allow adequate RF filtering.

Table B.1, Table B.2, and Table B.3 give some calculations of the subcarrier spacing, symbol duration and CP duration for different masks. The sampling rate is defined as \( F_s = BW \cdot \frac{8}{7} \), except for 256-OFDM (see 8.3.2.4) in licensed bandwidths, which are not a multiple of 1.75 MHz. In those cases, the sampling rate is \( F_s = BW \cdot \frac{7}{6} \).

### B.2 Frequency reuse of 1 for OFDMA

This subclause defines extensions of OFDMA system for working in deployment scenarios with frequency reuse of 1.

#### B.2.1 Introduction

The definition of an OFDMA system as defined in 8.4 is well suited to work with deployment scenarios with frequency reuse factor >1, but in order to satisfy requirement of reliability, coverage, capacity, spectral efficiency, and location base service. The system can be configured to work in a reuse of 1, which means the...
same RF frequency is allocated to all sectors in the cell. In this case, a new scheme of work shall be introduced in order to achieve the needed performance. A scenario using a reuse of 1 is given in Figure B.1.

![Figure B.1—Reuse of 1 configuration, 3 sectors per cell](image_url)

There are three options of operation in the reuse of 1 scenario:

- **Asynchronous configuration**—In this configuration, every BS uses its own permutation, the frame lengths and starting times are not synchronized among the BSs. Therefore, orthogonality is kept within the BS but not between BSs. In this scenario, the BSs could be synchronized or not to the same reference clock. This mode will introduce interference between BS (subcarriers from different subchannels collide in a controlled way, determined by the different permutations). This configuration could be easily used as an independent low-cost hot spot deployment (as an example).

- **Synchronous configuration**—In this configuration, all BSs use the same reference clock (for example, by using GPS), the frame durations and starting times are also synchronized among the BSs but still each BS uses different permutations. Therefore, the time/frequency orthogonality is kept between and within the BSs operation but still interference between the same subchannels of different BS occurs. Due to the time synchronization in this scenario and the long symbol duration of the OFDMA symbol, fast handoff as well as soft handoff is possible. This configuration could be used as an independent BSs deployment with a controlled interference level (as an example).

- **Coordinated Synchronous configuration**—In this configuration, all BSs work in the synchronous mode but use also the same permutations. An upper layer is responsible for the handling of subchannels allocations within the sectors of the BS, making sure that better handling of the bandwidth is achieved and the system could handle and balance load between the sectors and within the system. This mode is identical in performance as the regular coverage scenarios, beside the fact that the bandwidth allocated to each sector is only a portion of the overall bandwidth, but when using the load balancing additional system gain is achieved. This configuration could be used as a full scale system deployment, with a common backbone (as an example).

The preferred scenario is the coordinated synchronous mode (when using this configuration with different permutations per BS we get the synchronous mode, and do not use a synchronized clock between the BSs as well we end up with the asynchronous mode of operation); the configuration of the BS sectors are presented in Figure B.2.
Figure B.2—Reuse of 1 configuration, 3 sectors per cell
Annex C

(informative)

Example MAC common part sublayer service definition

C.1 MAC service definition

This annex describes the services between the MAC and the CSs. This is a logical interface. As such, the
primitives described are informative. Their purpose is to describe the information that must necessarily be
exchanged between the MAC and the CSs to enable each to perform its requirements as specified in the
remainder of this document. This subclause does not impose message formats or state machines for the use
of these primitives.

In a layered protocol system, the information flow across the boundaries between the layers can be defined
in terms of primitives that represent different items of information and cause actions to take place. These
primitives do not appear as such on the medium (the air interface) but serve to define more clearly the
relations of the different layers. The semantics are expressed in the parameters that are conveyed with the
primitives.

C.1.1 MAC service definition for PMP

C.1.1.1 Primitives

The IEEE 802.16 MAC supports the following primitives at the MAC SAP, to support services between the
MAC and the CSs in PMP mode.

- MAC_CREATE_SERVICE_FLOW.request
- MAC_CREATE_SERVICE_FLOW.indication
- MAC_CREATE_SERVICE_FLOW.response
- MAC_CREATE_SERVICE_FLOW.confirmation
- MAC_CHANGE_SERVICE_FLOW.request
- MAC_CHANGE_SERVICE_FLOW.indication
- MAC_CHANGE_SERVICE_FLOW.response
- MAC_CHANGE_SERVICE_FLOW.confirmation
- MAC_TERMINATE_SERVICE_FLOW.request
- MAC_TERMINATE_SERVICE_FLOW.indication
- MAC_TERMINATE_SERVICE_FLOW.response
- MAC_TERMINATE_SERVICE_FLOW.confirmation
- MAC_DATA.request
- MAC_DATA.indication

The use of these primitives to provide peer communication is shown in Figure C.1. The initial request for
service from a higher layer is provided by the “request” primitive. When this request is sent across the air
link to the peer MAC, it generates an “indicate” primitive to inform the peer CS of the request; the
convergence entity responds with a “response” to the MAC. Again this is sent across the air link to the MAC
on the originating side, which sends a “confirm” primitive to the original requesting entity.
In some cases, it is not necessary to send information to the peer station and the “confirm” primitive is issued directly by the MAC on the originating side. Such cases may occur, for example, when the request is rejected by the MAC on the requesting side. In cases where it is necessary to keep the other side of the link informed, an unsolicited “response” may be sent, in turn leading to the generation of an unsolicited “confirmation” for benefit of the CS.

For actions other than DATA.request and DATA.indication, the initiating CS sends a REQUEST primitive to its MAC. The initiating side MAC sends the appropriate Dynamic Service Addition, Change, or Deletion (DSx) Request message (see 6.3.14.7.1 and 6.3.14.8) to the receiving MAC. The noninitiating side MAC sends an INDICATION primitive to its CS. The noninitiating CS responds with a RESPONSE primitive, stimulating its MAC to respond to the initiating side MAC with the appropriate DSx Response message. The initiating side MAC responds to its CS with a CONFIRMATION primitive and, if appropriate, with the appropriate DSx Acknowledge message. At any point along the way, the request may be rejected (for lack of resources, etc.), terminating the protocol.

C.1.1.1.1 MAC_CREATE_SERVICE FLOW.request

C.1.1.1.1.1 Function

This primitive is issued by a CS entity in a BS or SS unit to request the dynamic addition of a connection.

C.1.1.1.1.2 Semantics of the service primitive

The parameters of the primitive are as follows:

```c
MAC_CREATE_SERVICE FLOW.request
(
    MAC Address
    scheduling service type,
    convergence sublayer,
    service flow parameters,
    payload header suppression indicator,
    encryption indicator,
    Packing on/off indicator,
    Fixed-length or variable-length SDU indicator,
    SDU length (only needed for fixed-length SDU connections),
    CRC request,
    ARQ parameters,
    sequence number
)
```
For connection requests initiated from a BS, the 48-bit MAC Address value identifies the SS with which the connection is to be established. The parameter has no significance for connection requests initiated from an SS.

The scheduling service type (see 6.3.5) is one of the following: UGS, rtPS, nrtPS, and BE service.

The convergence sublayer parameter indicates which CS handles data received on this connection. Values for specific CSs are given in 11.13.18.

The service flow parameters include details on such issues as peak and average rate, or reference to a service class. These parameters are the same as those in the DSC Request MAC Management message.

The payload header suppression indicator specifies whether the SDUs on the service flow are to have their headers suppressed.

The encryption indicator specifies that the data sent over this connection is to be encrypted, if ON. If OFF, then no encryption is used.

The packing on/off indicator specifies whether packing may be applied to the MAC SDUs on this connection. A value of ON means that packing is allowed for the connection.

The fixed-length or variable-length SDU indicator specifies whether the SDUs on the service flow are fixed-length or variable-length.

The SDU length specifies the length of the SDU for a fixed-length SDU service flow. The parameter has no significance for a variable length SDU service flow.

Cyclic redundancy check (CRC) request, if ON, requests that the MAC SDUs delivered over this connection are transported in MAC PDUs with a CRC added to them.

The ARQ parameters are whether ARQ is used for the connection, maximum retransmission limit, and acknowledgment window size.

The sequence number is used to correlate this primitive with its response from the BS via the MAC.

C.1.1.1.1.3 When generated

This primitive is generated by a CS of a BS or SS unit to request the BS to set up a new connection.

C.1.1.1.1.4 Effect of receipt

If the primitive is generated on the SS side, the receipt of this primitive causes the MAC to pass the request (in the form of a DSA-REQ message) to the MAC entity in the BS. The SS MAC remembers the correlation between sequence number and the requesting convergence entity.

If the primitive is generated on the BS side, the BS checks the validity of the request and, if valid, chooses a CID and includes it in the DSA-REQ message (6.3.14.9.3) sent to the SS. This CID shall be returned to the requesting CS via the CONFIRM primitive. If the primitive originated at the SS, the actions of generating a CID and authenticating the request are deferred to the INDICATION/RESPONSE portion of the protocol.
C.1.1.1.2 MAC_CREATE_SERVICE FLOW.indication

C.1.1.1.2.1 Function

This primitive is sent by the noninitiating MAC entity to the CS, to request the dynamic addition of a connection in response to the MAC receiving a DSA-REQ message. If the noninitiating MAC entity is at the BS, an SFID and possibly CID are generated and the request is authenticated.

C.1.1.1.2.2 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_CREATE_SERVICE FLOW.indication

(  
  service type,
  convergence sublayer,
  service flow parameters,
  sequence number
)

Parameters: see MAC_CREATE_SERVICE FLOW.request. The encryption and CRC flags are not delivered with the.indication primitive since they will have already been acted on by lower layers, to decrypt the data or to check a CRC, before the MAC SDU is passed up to the CS.

C.1.1.1.2.3 When generated

This primitive is generated by the MAC of the noninitiating side of the protocol when it receives a DSA-REQ message from the initiating side of the connection.

C.1.1.1.2.4 Effect of receipt

When the CS receives this primitive, it checks the validity of the request from the point of view of its own resources. It accepts or rejects the request via the MAC_CREATE_SERVICE FLOW.response primitive.

If the connection request was originated on the SS side, the BS sends the CID to the SS side in this RESPONSE primitive. Otherwise, if the origin was the BS, the RESPONSE contains the CID contained in the DSA header bearing the indication.

C.1.1.1.3 MAC_CREATE_SERVICE FLOW.response

C.1.1.1.3.1 Function

This primitive is issued by a noninitiating MAC entity in response to a MAC_CREATE_SERVICE FLOW.indication requesting the creation of a new connection.
C.1.1.1.3.2 Semantics of the service primitive

The parameters of the primitive are as follows:

\[
\text{MAC\_CREATE\_SERVICE\_FLOW.response} \\
( \\
\quad \text{Connection ID}, \\
\quad \text{response code}, \\
\quad \text{response message}, \\
\quad \text{sequence number}, \\
\quad \text{ARQ parameters} \\
\)
\]

The Connection ID is returned to the requester for use with the traffic specified in the request. If the request is rejected, then this value shall be ignored.

The response code indicates success or the reason for rejecting the request.

The response message provides additional information to the requester, in type/length/value (TLV) format.

The sequence number is returned to the requesting entity to correlate this response with the original request.

The ARQ parameters are whether ARQ is used for the connection, maximum retransmission limit, and acknowledgment window size.

C.1.1.1.3.3 When generated

This primitive is generated by the noninitiating CS entity when it has received a MAC\_CREATE\_SERVICE\_FLOW.indication.

C.1.1.1.3.4 Effect of receipt

The receipt of this primitive causes the MAC to send the DSA Response (DSA-RSP) message to the requesting MAC entity. Once the DSA Acknowledgment (DSA-ACK) is received, the MAC is prepared to pass data for this connection on to the air link.

C.1.1.1.4 MAC\_CREATE\_SERVICE\_FLOW.confirmation

C.1.1.1.4.1 Function

This primitive confirms to a convergence entity that a requested connection has been provided. It informs the CS of the status of its request and provides a CID for the success case.

C.1.1.1.4.2 Semantics of the service primitive

The parameters of the primitive are as follows:

\[
\text{MAC\_CREATE\_SERVICE\_FLOW.confirmation} \\
( \\
\quad \text{Connection ID}, \\
\quad \text{response code}, \\
\quad \text{response message}, \\
\quad \text{sequence number} \\
\)
\]
Parameters: see MAC_CREATE_SERVICE FLOW.response.

**C.1.1.1.4.3 When generated**

This primitive is generated by the initiating side MAC entity when it has received a DSA-RSP message.

**C.1.1.1.4.4 Effect of receipt**

The receipt of this primitive informs the convergence entity that the requested connection is available for transmission requests.

**C.1.1.1.5 Changing an existing connection**

Existing connections may be changed in their characteristics on a dynamic basis to, for example, reflect changing bandwidth requirements. The following primitives are used:

- MAC_CHANGE_SERVICE FLOW.request
- MAC_CHANGE_SERVICE FLOW.indication
- MAC_CHANGE_SERVICE FLOW.response
- MAC_CHANGE_SERVICE FLOW.confirmation

The semantics and effect of receipt of these primitives are the same as for the corresponding CREATE primitives. A new CID shall be generated in the case of changing a service flow type from provisioned to admitted or active.

**C.1.1.1.6 MAC_TERMINATE_SERVICE FLOW.request**

**C.1.1.1.6.1 Function**

This primitive is issued by a CS entity in a BS or SS unit to request the termination of a connection.

**C.1.1.1.6.2 Semantics of the service primitive**

The parameters of the primitive are as follows:

```plaintext
MAC_TERMINATE_SERVICE FLOW.request
(  
  SFID

)```

The SFID parameter specifies which service flow is to be terminated.

**C.1.1.1.6.3 When generated**

This primitive is generated by a CS of a BS or SS unit to request the termination of an existing connection.

**C.1.1.1.6.4 Effect of receipt**

If the primitive is generated on the SS side, the receipt of this primitive causes the MAC to pass the request to the MAC entity in the BS via the DSD Request (DSD-REQ) message. The BS checks the validity of the request, and if it is valid it terminates the connection.

If the primitive is generated on the BS side, it has already been validated and the BS MAC informs the SS by issuing a DSD-REQ message.
C.1.1.1.7 MAC_TERMINATE_SERVICE FLOW.indication

C.1.1.1.7.1 Function

This primitive is issued by a the MAC entity on the noninitiating side to request the termination of a connection in response to the receipt of a DSD-REQ message.

C.1.1.1.7.2 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_TERMINATE_SERVICE FLOW.indication
  (SFID)

The SFID parameter specifies which service flow is to be terminated.

C.1.1.1.7.3 When generated

This primitive is generated by the MAC when it receives a DSD-REQ message to terminate a connection, or when it finds it necessary for any reason to terminate a connection.

C.1.1.1.7.4 Effect of receipt

If the protocol was initiated by the SS, when it receives this primitive, the BS checks the validity of the request. In any case, the receiving CS returns the MAC_TERMINATE_SERVICE FLOW.response primitive and deletes the SFID from the appropriate polling and scheduling lists.

C.1.1.1.8 MAC_TERMINATE_SERVICE FLOW.response

C.1.1.1.8.1 Function

This primitive is issued by a CS entity in response to a request for the termination of a connection.

C.1.1.1.8.2 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_TERMINATE_SERVICE FLOW.response
  (SFID,
   response code,
   response message)

The SFID is returned to the requesting entity.

The response code indicates success or the reason for rejecting the request.

The response message provides additional information to the requester, in TLV format.
C.1.1.1.8.3 When generated

This primitive is generated by the CS entity when it has received a MAC_TERMINATE_SERVICE FLOW.indication from its MAC.

C.1.1.1.8.4 Effect of receipt

The receipt of this primitive causes the MAC to pass the message to the initiating side via the DSD Response (DSD-RSP) message. The initiating MAC in turn passes the CONFIRM primitive to the requesting convergence entity. The convergence entity shall no longer use this CID for data transmission.

C.1.1.1.9 MAC_TERMINATE_SERVICE FLOW.confirmation

C.1.1.1.9.1 Function

This primitive confirms to a convergence entity that a requested connection has been terminated.

C.1.1.1.9.2 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_TERMINATE_SERVICE FLOW.confirmation
  (SFID,
   response code,
   response message)

Parameters: see MAC_TERMINATE_SERVICE FLOW.response.

C.1.1.1.9.3 When generated

This primitive is generated by the MAC entity when it has received a DSD-RSP message.

C.1.1.1.9.4 Effect of receipt

The receipt of this primitive informs the convergence entity that a connection has been terminated. The convergence entity shall no longer use this CID for data transmission.

C.1.1.1.10 MAC_DATA.request

C.1.1.1.10.1 Function

This primitive defines the transfer of data to the MAC entity from a CS SAP.
C.1.1.1.11 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_DATA.request

(  
    Connection ID,  
    length,  
    data,  
    discard-eligible flag  
    encryption flag  
)

The Connection ID parameter specifies the connection over which the data is to be sent; the service class is implicit in the Connection ID parameter.

The length parameter specifies the length of the MAC SDU in bytes.

The data parameter specifies the MAC SDU as received by the local MAC entity.

The discard-eligible flag specifies whether the MAC SDU is to be preferentially discarded by the scheduler in the event of link congestion and consequent buffer overflow.

The encryption flag specifies that the data sent over this connection is to be encrypted, if ON. If OFF, then no encryption is used.

C.1.1.1.11.1 When generated

This primitive is generated by a CS whenever a MAC SDU is to be transferred to a peer entity or entities.

C.1.1.1.11.2 Effect of receipt

The receipt of this primitive causes the MAC entity to process the MAC SDU through the MAC and to pass the appropriately formatted PDUs to the PHY TCS for transfer to peer MAC entities, using the CID specified.

C.1.1.1.12 MAC_DATA.indication

C.1.1.1.12.1 Function

This primitive defines the transfer of data from the MAC to the CS. The specific CS to receive the indicate message is implicit in the CID.

C.1.1.1.12.2 Semantics of the service primitive

The parameters of the primitive are as follows:

MAC_DATA.indication

(  
    Connection ID,  
    length,  
    data,  
    reception status,  
)

The Connection ID parameter specifies the connection over which the data was sent.

The length parameter specifies the length of the data unit in bytes.

The data parameter specifies the MAC SDU as received by the local MAC entity.

The reception status parameter indicates transmission success or failure for those PDUs received via the MAC_DATA.indication.

### C.1.1.1.12.3 When generated

This primitive is generated whenever an MAC SDU is to be transferred to a peer convergence entity or entities.

### C.1.1.1.12.4 Effect of receipt

The effect of receipt of this primitive by a convergence entity is dependent on the validity and content of the MAC SDU. The choice of CS is determined by the CID over which the MAC SDU was sent.

### C.1.1.2 MAC service stimulation of DSx messages

This subclause describes the logical interaction between the MAC Service primitives and the DSx messages.

The sequence of logical MAC SAP events and the associated actual MAC events effecting a CS-stimulated connection creation are shown in Figure C.2.

![Diagram](image-url)
The sequence of logical MAC SAP events and the associated actual MAC events effecting a CS-stimulated connection change are shown in Figure C.3.

![Figure C.3—MAC SAP event and MAC event sequence for connection change stimulated by CS](image)

The sequence of logical MAC SAP events and the associated actual MAC events effecting a CS-stimulated connection deletion are shown in Figure C.4.

![Figure C.4—MAC SAP event and MAC event sequence for connection deletion stimulated by CS](image)
Annex D

(informative)

Messages sequence charts (MSCs)

This annex provides example MSCs for the procedures of HO and sleep mode operations.

D.1 HO MSCs

D.1.1 Neighbor BS advertisement and scanning

Figure D.1 through Figure D.6 describe the example message flows for neighbor BS advertisements and scanning of neighbors by the MS request, BS request, and periodic scanning of neighbors during HO.
Figure D.1—Example Neighbor BS advertisement and scanning (without association) by MS request.

MOB_NBR-ADV (N_NEIGHBORS = 2) 
MOB_SCN-REQ (Scan duration = N frames, Interleaving interval = P frames, Iteration=T times) 
MOB_SCN-RSP (start frame = M frames, duration = N frames) 

Synchronize with BS#2, measure metrics 
Synchronize with BS#3, measure metrics 

Iteration #1 
Non-scanning interleaving interval (P frames) 
Scanning interval duration = N frames 

Iteration #2 
Alternation of scanning interval and interleaving interval 
Scanning interval duration = N frames 

Iteration #T 
Scanning interval duration = N frames 

Data Traffic (if any) 

Synchronize with BS#2, measure metrics 
Synchronize with BS#3, measure metrics 

M frames 
Scanning interval duration = N frames 

Synchronize with BS#2, measure metrics 
Synchronize with BS#3, measure metrics
Figure D.2—Example Neighbor BS advertisement and scanning
(with noncoordinated association) by MS request
Figure D.3—Example Neighbor BS advertisement and scanning (without association) by BS request
Figure D.4—Example Neighbor BS advertisement and scanning (with association) by BS request
Figure D.5—Example macro diversity HO (diversity set update: add)
Figure D.6—Example macro diversity HO (diversity set update: drop)
D.2 Sleep mode MSCs

Figure D.7, Figure D.8, and Figure D.9 describe the example message flows for sleep mode initiated by an MS, sleep mode initiated by a BS, and sleep mode awakening initiated by an MS, respectively.

Figure D.7—Example sleep mode—MS-initiated in the case of TRF_IND_required = 1 and Traffic_Triggered_wakening_flag = 1

- MS
  - MOB_SLP-REQ
    - (Min-sleeping interval = N1)
    - (Max-sleeping interval = N2)
    - (Listening interval = L1)
  - MOB_SLP-RSP
    - (Start time = M)
    - (Min-sleeping interval = N1)
    - (Max-sleeping interval = N2)
    - (Listening interval = L1)
  - MOB_TRF-IND
    - (Negative indication)
  - MOB_TRF-IND
    - (Positive indication)

- BS
  - LSB of Frame_Number = M
  - Listening, for L' frames
  - Sleep mode for N1 frames
  - Listening, for L' frames
  - Sleep mode for 2*N1 frames*
  - Listening, for L' frames
  - Normal Operation

* Counted from the last expiration of Sleep Interval
Figure D.8—Example sleep mode—BS-initiated for the case of TRF_IND = 1 and Traffic_triggering_wakening_flag = 1
Figure D.9—Sleep mode—MS-initiated awakening
Annex E

(informative)

HO block diagrams

E.1 HO initiated by MS

Figure E.1 and Figure E.2 provide example block diagrams for HO procedures initiated by an MS.
Figure E.1—MS-initiated HO process block diagram as seen by MS
Figure E.2—MS-initiated HO process block diagram as seen by serving BS
where final target BS is selected by serving BS
E.2 HO initiated by BS

Figure E.3 and Figure E.4 provide example block diagrams for HO procedures initiated by a BS.

![Block Diagram](image)

**Figure E.3**—BS-initiated HO process block diagram as seen by MS
Send MOB_NBR-ADV to MS

Need to HO?

Yes

Exchange messages over the backbone network for pre-notifying target BS to indicate a HO for the MS

Send MOB_BSHO-REQ to MS

Receive MOB_HO-IND from MS

Release MS

Figure E.4—BS-initiated HO process block diagram as seen by serving BS

Annex G

(informative)

**LDPC direct encoding**

The LDPC code is flexible in that it can accommodate various code rates as well as packet sizes.

The encoding of a packet at the transmitter generates parity-check bits \( p = (p_0, \ldots, p_{m-1}) \) based on an information block \( s = (s_0, \ldots, s_{k-1}) \), and transmits the parity-check bits along with the information block. Because the current symbol set to be encoded and transmitted is contained in the transmitted codeword, the information block is also known as systematic bits. The encoder receives the information block \( s = (s_0, \ldots, s_{k-1}) \) and uses the matrix \( H_{bm} \) to determine the parity-check bits. The expanded matrix \( H \) is determined from the model matrix \( H_{bm} \). Since the expanded matrix \( H \) is a binary matrix, encoding of a packet can be performed with vector or matrix operations conducted over GF(2).

One method of encoding is to determine a generator matrix \( G \) from \( H \) so that \( GH^T = 0 \). A \( k \)-bit information block \( s_1 \times k \) can be encoded by the code generator matrix \( G_{k \times n} \) via the operation \( x = s \cdot G \) to become an \( n \)-bit codeword \( x = [s \ p] = [s_0, s_1, \ldots, s_{k-1}, p_0, p_1, \ldots, p_{m-1}] \), where \( p_0, \ldots, p_{m-1} \) are the parity-check bits; and \( s_0, \ldots, s_{k-1} \) are the systematic bits.

Encoding an LDPC code from \( G \) can be quite complex. The LDPC codes are defined so that very low complexity encoding directly from \( H \) is possible.

The following informative subclause shows two such methods.

**G.1 Method 1a**

Encoding is the process of determining the parity sequence \( p \) given an information sequence \( s \). To encode, the information block \( s \) is divided into \( k_b = n_b - m_b \) groups of \( z \) bits. Let this grouped \( s \) be denoted \( u \),

\[
u = [u(0) \ u(1) \ldots \ u(k_b-1)].
\]

where each element of \( u \) is a column vector as follows:

\[
u(i) = \begin{bmatrix} S_{iz} & S_{iz+1} & \ldots & S_{i(z+1)z-1} \end{bmatrix}^T
\]

Using the model matrix \( H_{bm} \), the parity sequence \( p \) is determined in groups of \( z \). Let the grouped parity sequence \( p \) be denoted \( v \),

\[
v = [v(0) \ v(1) \ldots \ v(m_b-1)].
\]

where each element of \( v \) is a column vector as follows:

\[
v(i) = \begin{bmatrix} p_{iz} & p_{iz+1} & \ldots & p_{(i+1)z-1} \end{bmatrix}^T
\]

Encoding proceeds in two steps, (1) initialization, which determines \( v(0) \), and (2) recursion, which determines \( v(i+1) \) from \( v(i) \), \( 0 \leq i \leq m_b - 2 \).
An expression for \( v(0) \) can be derived by summing over the rows of \( \mathbf{H}_{\text{bm}} \) to obtain Equation (G.1).

\[
P_{p(x, \ell)} v(0) = \sum_{j=0}^{k_x-1} \sum_{i=0}^{m_x-1} P_{p(x, \ell)} u(j)
\]

where \( x, 1 \leq x \leq m_x - 2 \), is the row index of \( \mathbf{H}_{\text{bm}} \) where the entry is nonnegative and unpaired, and \( \mathbf{P}_i \) represents the \( z \times z \) identity matrix circularly right shifted by size \( i \).

Equation (G.2) is solved for \( v(0) \) by multiplying by \( P^{-1}_{p(x, \ell)} \), and \( P^{-1}_{p(x, \ell)} = P_{x-p(x, \ell)} \) since \( p(x, \ell) \) represents a circular shift.

Considering the structure of \( \mathbf{H}'_{\text{b2}} \), the recursion can be derived as follows in Equation (G.2) and Equation (G.3).

\[
v(1) = \sum_{j=0}^{k_x-1} P_{p(x, \ell)} u(j) + P_{p(x, \ell)} v(0), \ i = 0,
\]

\[
v(i+1) = v(i) + \sum_{j=0}^{k_x-1} P_{p(x, \ell)} u(j) + P_{p(x, \ell)} v(0), \ i = 1, \ldots, m_x - 2
\]

where

\[
P_{-1} = 0_{z \times z}
\]

Thus all parity bits not in \( v(0) \) are determined by evaluation Equation (G.3) for \( 0 \leq i \leq m_x - 2 \). Equation (G.1), Equation (G.2), and Equation (G.3) completely describe the encoding algorithm. These equations also have a straightforward interpretation in terms of standard digital logic architectures. Since the nonzero elements \( p(i, j) \) of \( \mathbf{H}_{\text{bm}} \) represent circular shift sizes of a vector, all products of the form \( P_{p(i, j)} u(j) \) can be implemented by a size-\( z \) barrel shifter.

### G.4 Method 1b

Equivalently, Method 1 can be implemented in a parallel fashion where almost all parity check parity bits are generated simultaneously. The initialization and the recursion steps of Method 1 become

- **Initialization.** The parity check bit vector \( v(0) \) are computed by Equation (G.4).

\[
P_{p(x, \ell)} v(0) = \sum_{j=0}^{k_x-1} \sum_{q=0}^{m_x-1} P_{p(x, \ell)} u(j)
\]

- **Parallel computation.** The parity check bit vectors \( v(1) - v(m_x - 1) \) are concurrently computed by Equation (G.5).

\[
v(i) = \sum_{j=0}^{k_x-1} \sum_{q=0}^{m_x-1} P_{p(i, j)} u(j) + \sum_{q=i}^{m_x-1} P_{p(i, \ell)} v(0) i = 1, \ldots, m_x - 1
\]
The parallel encoding method may significantly reduce the latency at the expense of extra storage for the sum

\[
\left\{ \sum_{q=1}^{m_z-1} P_{p(q,j)} \right\}
\]

**G.6 Method 2**

For efficient encoding of LDPC, \( H \) are divided into the form of Equation (G.6).

\[
H = \begin{bmatrix} A & B \end{bmatrix} T \begin{bmatrix} C & D & E \end{bmatrix}
\]

(G.6)

where \( A \) is \( (m-z) \times k \alpha \), \( B \) is \( (m-z) \times z \), \( T \) is \( (m-z) \times (m-z) \), \( C \) is \( z \times k \), \( D \) is \( z \times z \), and finally \( E \) is \( z \times (m-z) \).

Let \( v = (u, p_1, p_2) \) where \( u \) denotes the systematic part, \( p_1 \) and \( p_2 \) combined denote the parity part, \( p_1 \) has length \( z \), and \( p_2 \) has length \( (m-z) \). The definition equation \( (H \cdot v)^\top = 0 \) splits into two equations, as in Equation (G.7) and Equation (G.8).

\[
Au^\top + Bp_1^\top + Tp_2^\top = 0
\]

(G.7)

and

\[
(ET^{-1}A + C)u^\top + (ET^{-1}B + D)p_1^\top = 0
\]

(G.8)

Define \( \phi : = (ET^{-1}B + D) \) and with the parity check matrix as indicated \( \phi = I \). Then from Equation (G.8), it can be concluded that

\[
P_1^\top = (ET^{-1}A + C)u^\top
\]

(G.9)

and

\[
P_2^\top = T^{-1}(Au^\top + Bp_1^\top)
\]

(G.10)
As a result, the encoding procedures and the corresponding operations can be summarized below and illustrated in Figure G.1.

![Block diagram of the encoder architecture for the block LDPC code](image)

**Figure G.1—Block diagram of the encoder architecture for the block LDPC code**

### G.2 Encoding procedure

1. Compute $A u^T$ and $C u^T$
2. Compute $E T^{-1}(A u^T)$
3. Compute $p_1^T$ by $p_1^T = E T^{-1}(A u^T) + C u^T$
4. Compute $p_2^T$ by $p_2^T = A u^T + B p_1^T$
Annex H

    DESCRIPTION
        "This material is from IEEE Std 802.16f-2005
Copyright (c) 2005 IEEE.
This MIB Module provides the example of how to define
vendor specific managed objects for IEEE 802.16-2004
based Base Station to provide critical remote monitoring
functions, and is located under the Private MIB subtree.
This MIB is not intended to be used directly as defined
here. Instead enterprise developers should follow this
example when defining their private MIBs.
For example:
iso(1).org(3).dod(6).internet(1).private(4).enterprises(1)
   .intel(343).wmanPriMib(1)"
    REVISION        "200508020000Z"

Annex I

(informative)

Alternative variation of replay protection for management messages in limited mobility environment

I.1 Introduction

The text below supports the legacy CMAC key generation algorithms. This legacy CMAC key generation algorithm is designated CMAC-0.

If bit 1 in the MAC Mode TLV in 11.8.4.3 TLV in the SBC-REQ message that is sent by the MS, is set to ‘1’, the BS may choose to invoke the CMAC-0 mode of CMAK_KEY generation. To invoke this mode, the BS shall set Bit 1 in the MAC Mode TLV of the SBC-RSP message to ‘1’.

(Refer to 7.2.2.2.9.)

I.2 CMAC-0 Keys Derivation

If bit 1 of the MAC Mode TLV is set to ‘1’ (see 11.8.4.3), the keys used for CMAC key and for KEK are derived as follows:

\[
\text{CMAC\_KEY\_U} | \text{CMAC\_KEY\_D} | \text{KEK} \leftarrow \text{Dot16KDF}(\text{AK}, \text{SS MAC Address} | \text{BSID} | \text{"CMAC\_KEYS+KEK"}, 384)
\]

\[
\text{CMAC\_KEY\_GD} \leftarrow \text{Dot16KDF}(\text{GKEK}, \text{"GROUP CMAC KEY"}, 128) \text{ (Used for broadcast MAC message such as a PKMv2 Group-Key-Update-Command message for GTEK Update Mode)}
\]

I.3 Caching Requirement and HMAC/CMAC\_PN\_* Counters

(Refer to 7.2.2.4.1.)

For the CMAC-0 mode, if the cached AK and associated context is lost by either the BS or SS, no new AKs can be derived on handover.

For the CMAC-0 mode, the initial values of the CMAC\_PN\_* counters are zero. These counters are cached by the MS and BS for the life of the AK.

I.4 CMAC-0 Key Derivation figure

Refer to Figure I.1.

U-TDOA measurement

Annex K describes two methods for U-TDOA measurement: the General U-TDOA Method, for any FRF (Frequency Reuse Factor); and the Special U-TDOA Method, for FRF = 1. Figure K.1 shows a diagram for U-TDOA measurement.

The U-TDOA measurement algorithm is based on the ranging mechanism as specified in this standard. The ranging capability is primarily designed to allow an MS to synchronize with a BS in terms of time and frequency and may not provide sufficient accuracy for LBS applications such as E911 Phase II. It is recommended that the Automatic Timing Correction (ATC) algorithm in the BS should use better resolution (e.g., in the increments of 50 ns or 25 ns) than what is required for the timing adjustment increments of the ranging procedure.

K.1 General U-TDOA method

When the position of an MS is determined using U-TDOA, the MS ranges with the serving BS and two or more neighboring BSs. Figure K.2 shows an example of a timing diagram of U-TDOA measurement. This example is based on the following assumptions:
a) The MS aligns the frame start to the received DL from the serving BS before ranging with the serving BS.
b) The MS aligns the frame start to the received DL from the neighbor BS before ranging with the neighbor BS.
c) The MS does not make any timing adjustments relatively to the aligned frame start between ranging with the two BS.

BS calculates $t_2$ and $t_3$ during the ranging process.

---

**Figure K.2—U-TDOA Measurement Timing diagram (General U-TDOA method)**

The MS ranges sequentially with the serving BS and neighbor BS. The serving BS and the neighbor BS measure the Timing Adjustment $t_2$ and $t_3$ respectively, and the neighbor BS reports $t_3$ to the serving BS. The serving BS calculates the difference in propagation delay = $(t_2 - t_3)/2$ and, by multiplying this difference by the speed of light, the difference of the MS’s distance to the serving BS and neighbor BS.

The call flow in Figure K.3 shows the messaging between an MS, its serving BS and a neighbor BS in support of U-TDOA. The call flow can be extended to support additional neighbor BSs. The following are the assumptions for the call flow:

— Serving BS and neighbor BS are operating with the same frame sizes.
— The frames at the serving BS and neighbor BS are synchronized.
— MS can communicate with the serving BS and neighbor BS.
1) Serving BS requests neighbor BS to assign the dedicated ranging opportunity for the MS.

2) Neighbor BS confirms the allocation of the dedicated ranging opportunity for the MS and returns the related parameters used for dedicated ranging between the MS and the neighbor BS.
   - Frame Number
   - CDMA code
   - Transmission opportunity offset

3) Serving BS allocates a CDMA code and transmission opportunity for dedicated ranging between the MS and the Serving BS.

4) Serving BS sends an unsolicited RNG-RSP message to the MS to request the MS to initiate dedicated ranging. The following parameters are included in this message:
   - Rendezvous time
   - CDMA code
   - Transmission opportunity offset

---

**Figure K.3**—U-TDOA measurement algorithm (General U-TDOA method)

---
5) Serving BS allocates a dedicated ranging region and signals it in the UL-MAP in the frame immediately following the rendezvous time sent in the RNG-RSP message in step 4). Serving BS sets the dedicated ranging indicator in the UL-MAP_IE to 1.

6) If there is a dedicated ranging region at the rendezvous time, the MS determines the specific region it should use for transmission of the dedicated CDMA code by applying the offset defined by the “transmission opportunity offset” field in RNG-RSP message received in step 4) to the dedicated ranging region definition in the UL-MAP received from Serving BS.

7) Serving BS measures Timing Adjustment $t_2$

8) Serving BS sends autonomous MOB_SCN-RSP with scanning type = 0b10 (scan association with coordination) to force MS performing initial ranging after scan. The related parameters assigned by neighbor BS are included in the MOB_SCN-RSP message.
   — Rendezvous time
   — CDMA code
   — Transmission opportunity offset

9) Neighbor BS allocates a dedicated ranging region and signals it in the UL-MAP in the frame immediately following the rendezvous time sent in the MOB_SCN-RSP message sent in step 8). The BS sets the dedicated ranging indicator in the UL-MAP_IE to 1.

10) If there is a dedicated ranging region at the rendezvous time, the MS determines the specific region it should use for transmission of the dedicated CDMA code by applying the offset defined by the “transmission opportunity offset” field in the MOB_SCN-RSP message received in step 8) to the dedicated ranging region definition in the UL-MAP received from neighbor BS.

11) Neighbor BS receives the assigned CDMA code, and measures Timing Adjustment $t_3$.

12) Neighbor BS returns RNG-RSP to MS.

13) Neighbor BS returns $t_3$ to serving BS.

14) Serving BS calculates the U-TDOA as follows: $T_1 = \frac{(t_2 - t_3)}{2}$

**K.2 Special U-TDOA method**

When the position of an MS is determined using U-TDOA, the MS ranges with the serving BS and two or more neighboring BSs. Figure K.4 shows an example of a timing diagram of U-TDOA measurement.
In this example, the MS transmits a CDMA code that is received by both the serving BS and neighbor BS. The serving BS and neighbor BS measure Timing Adjustment $t_2$ and $t_3$ respectively, and the neighbor BS reports $t_3$ to the serving BS. The serving BS calculates the difference in propagation delay $= t_2 - t_3$ and, by multiplying this difference by the speed of light, determines the difference of the MS's distance to the serving BS and neighbor BS.

Figure K.5 shows the U-TDOA measurement algorithm that includes a neighbor BS. The algorithm can be duplicated to support additional neighbor BS. Here are the assumptions for the algorithm.

- Serving BS and neighbor BS are operating on the same band (Frequency reuse = 1)
- Serving BS and neighbor BS are operating on the same frame duration
- The frames in both serving BS and neighbor BS are synchronized
- MS can communicate with both serving BS and neighbor BS
1) Serving BS and neighbor BS negotiate the allocation of a dedicated ranging region for the MS.
   — Frame Number
   — Transmission opportunity offset
   — Number of Symbols
   — CDMA code
   — Power Level

2) Serving BS sends an unsolicited RNG-RSP message to the MS to request the MS to initiate dedicated ranging. The following parameters are included in this message:
   — Rendezvous time
   — CDMA code
   — Transmission opportunity offset

3) The serving BS allocates a dedicated ranging region for the MS to do dedicated ranging at the pre-assigned rendezvous time and listens to the dedicated ranging code from the MS.

4) At the same time, the neighbor BS shall make no allocations in that dedicated ranging region, and the neighbor BS listens for the dedicated ranging code from the MS.

5) If there is a dedicated ranging region at the rendezvous time, the MS determines the specific region it should use for transmission of the dedicated CDMA code by applying the offset defined by the “transmission opportunity offset” field in RNG-RSP message received in step 2) to the dedicated ranging region definition in the UL-MAP received from Serving BS. The transmission power shall be changed based on the power level adjust parameter included in the received RNG-RSP message to allow the neighbor BS to receive the code successfully.

6) The neighbor BS measures Timing Adjustment \( t_3 \).

7) The serving BS measures Timing Adjustment \( t_2 \).

8) The neighbor BS returns \( t_3 \) to serving BS.

9) Serving BS calculates the U-TDOA as follows: \( T_1 = t_2 - t_3 \)
Annex L

(informative)

Example Encapsulation of an IEEE 802.16 entity

L.1 Introduction

Figure 1 in 1.4 of this standard shows the IEEE 802.16 entity reference model.

The Network Control and Management System (NCMS) is not part of IEEE 802.16 standards and is treated as a “black box.” It may be distributed with parts residing on different nodes in a network. Part of the NCMS may be physically collocated with the IEEE 802.16 entity. In this annex, this part is referred to as NCMS-E. The remaining part of the NCMS may be physically distributed across one or more other network entities. This part of the NCMS is referred to as NCMS-N. Figure L.1 shows the partition of the NCMS into NCMS-E and NCMS-N.

![Figure L.1—Possible distribution of the NCMS](image)

The NCMS-E may have its own software platform and network protocol implementation allowing it to communicate with external entities in the NCMS-N.

L.1.1 SNMP Agent

NCMS-E may provide an SNMP Agent compliant to IETF RFC 3418 and the SNMP/TCP/IP protocol stack to allow for interactions with an SNMP manager. Subclause 9.4.1 provides some specific requirements for BSs and SSs implementing the SNMP protocol.
L.1.2 CORBA

The NCMS-E may provide an Object Request Broker (ORB) and implement a communications protocol stack such as IIOP/TCP/IP allowing it to interact with components on other network entities within NCMS-N based on the CORBA architecture. The messages available to a manager in the NCMS-N are specified using Interface Description Language (IDL). These messages encapsulate the interactions with the MIB.

L.1.3 Web services

The IEEE 802.16 entity could be managed through Web Services. In this case, the NCMS-E may support the SOAP/HTTP/TCP/IP protocol stack, which would be used between a manager in the NCMS and the NCMS-E to exchange XML-based messages. The WSs, which encapsulate access to the MIB, may be described using WS Description Language (WSDL).
Annex M

(informative)

Network Control and Management System (NCMS)

This abstraction is detailed in Figure M.1 to show the different functional entities that make up such a Network Control and Management System. These entities may be centrally located or distributed across the network. The exact functionality of these entities and their services is outside the scope of this standard, but shown here for illustration purposes and to better enable the description of the management and control procedures.

![Network Control and Management System Diagram](image)

**Figure M.1—Illustration of the Network Control and Management System (Informative)**

NCMS protocols are not defined in this standard; however, information elements (IEs) and protocol primitives for these IEs are exposed using primitives via SAP. This includes MAC and PHY layer context information used by NCMS protocols to manage and control the air interface. NCMS service manifestations on the SS/MS and BS may have different configurations and functions.

NOTE—For the NAS-Port-Type RADIUS Attribute 61 (IETF RFC 2865), the IEEE 802.16 AAA service in the NCMS is assigned the value “27.”
Annex N

(informative)

Processing of CMAC_KEY_COUNT by the authenticator

The Authenticator is assumed to maintain the CMAC_KEY_COUNTN for every MS as part of its security context, called the AK Context, associated with each PMK.

Upon successful completion of the PKMv2 Authentication or Re-authentication, and creation of a new PMK, the Authenticator sets the CMAC_KEY_COUNTN for the MS to 1. In particular, setting the counter to 1 occurs when the Authenticator receives indication about the successful completion of EAP-based authentication. The Authenticator never sets the value to zero and only sets the value to 1 after a new PMK has been established. Effectively, the Authenticator maintains the next expected value of the CMAC_KEY_COUNT to be reported by the MS during the next access.

Upon receiving a request for the AK context from the BS, the Authenticator returns the current value of CMAC_KEY_COUNTN.

Upon receiving the indication of a successful Secure Location Update or network re-entry from a BS or an indication of a handover cancellation from the serving BS containing the CMAC_KEY_COUNTM, the Authenticator compares it to the locally maintained value of CMAC_KEY_COUNTN and selects the largest of the two as the valid value of the counter, and then increments the value of the counter by one, i.e.,

\[ \text{CMAC_KEY_COUNT}_N = \max(\text{CMAC_KEY_COUNT}_N, \text{CMAC_KEY_COUNT}_M) + 1 \]
