

3GPP TS 33.402 V10.1.0 (2011-09)

Technical Specification

**3rd Generation Partnership Project;
Technical Specification Group Services and System Aspects;
3GPP System Architecture Evolution (SAE);
Security aspects of non-3GPP accesses
(Release 10)**

The present document has been developed within the 3rd Generation Partnership Project (3GPP™) and may be further elaborated for the purposes of 3GPP.

The present document has not been subject to any approval process by the 3GPP Organizational Partners and shall not be implemented. This Specification is provided for future development work within 3GPP only. The Organizational Partners accept no liability for any use of this Specification. Specifications and reports for implementation of the 3GPP™ system should be obtained via the 3GPP Organizational Partners' Publications Offices.

Foreword

This Technical Specification has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

- x the first digit:
 - 1 presented to TSG for information;
 - 2 presented to TSG for approval;
 - 3 or greater indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the document.

1 Scope

The present document specifies the security architecture, i.e., the security feature groups and the security mechanisms performed during inter working between non-3GPP accesses and the Evolved Packet System (EPS).

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document *in the same Release as the present document*.

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in TR 21.905 [1] and the following apply. A term defined in the present document takes precedence over the definition of the same term, if any, in TR 21.905 [1].

IPsec Security Association (IPsec SA): A unidirectional logical connection created for security purposes. All traffic traversing an IPsec SA is provided the same security protection. The IPsec SA itself is a set of parameters to define security protection between two entities. An IPsec SA includes the cryptographic algorithms, the keys, the duration of the keys, and other parameters.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

S2a	This interface is defined in TS 23.402 [05].
S7a	Interface between a PCRF and a HS-GW
S101	Interface between a MME and a HRPD AN
S103	Interface between a SGW and a HS-GW

3.3 Abbreviations

For the purposes of the present document, the abbreviations given in TR 21.905 [1] and the following apply. An abbreviation defined in the present document takes precedence over the definition of the same abbreviation, if any, in TR 21.905 [1].

AAA	Authentication Authorisation Accounting
AES	Advanced Encryption Standard
AKA	Authentication and Key Agreement
ANDSF	Access Network Discovery and Selection Function
DSMIPv6	Dual-Stack MIPv6
EAP	Extensible Authentication Protocol

EPC	Evolved Packet Core
ePDG	Evolved Packet Data Gateway
EPS	Evolved Packet System
ESP	Encapsulating Security Payload
E-UTRAN	Evolved UTRAN
HS-GW	HRPD Serving GW
IKEv2	Internet Key Exchange Version 2
IPsec	IP security protocols, algorithms, and key management methods
LMA	Local Mobility Anchor
MAG	Mobile Access Gateway
MIPv4	Mobile IP version 4
MIPv6	Mobile IP version 6
MME	Mobility Management Entity
NDS	Network Domain Security
NDS/IP	NDS for IP based protocols
PMIP/PMIPv6	Proxy Mobile IP version 6
SA	Security Association
UICC	Universal Integrated Circuit Card
USIM	Universal Subscriber Identity Module

3.4 Conventions

All data variables in the present document are presented with the most significant substring on the left hand side and the least significant substring on the right hand side. A substring may be a bit, byte or other arbitrary length bitstring. Where a variable is broken down into a number of substrings, the leftmost (most significant) substring is numbered 0, the next most significant is numbered 1, and so on through to the least significant.

4 Overview of Security Architecture for non-3GPP Accesses to EPS

4.1 General

The following subclauses outline an overview of the security architecture for trusted and untrusted non-3GPP accesses to connect to 3GPP EPS. It outlines the needed security features to connect such a non-3GPP access to the 3GPP EPS. Non-3GPP access specific security is outside the scope of the present document.

Figure 4.1-1 gives an overview of the security architecture of a typical non-3GPP access while connected to the 3GPP EPC.

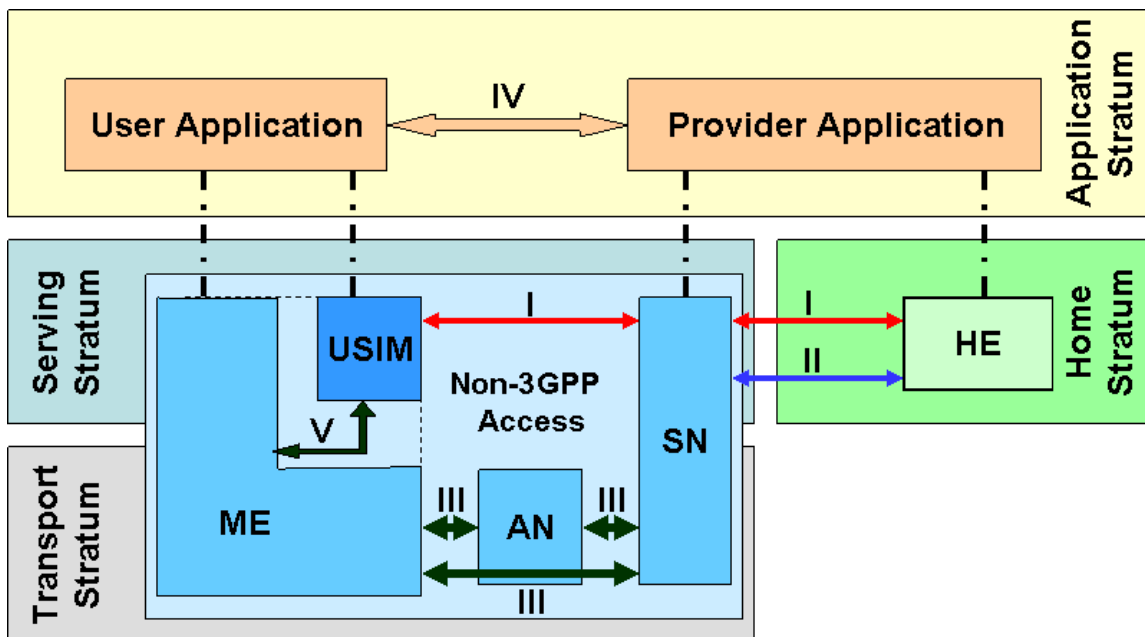

Figure 4.1-1: Security Architecture of Non-3GPP Access and 3GPP EPS

NOTE: USIM applies in case of terminal with 3GPP access capabilities, cf. clause 6.1.

Five security feature groups are defined. Each of these feature groups accomplishes certain security objectives:

- **Network access security (I):** the set of security features that provide users with secure access to services while terminated at 3GPP EPC. Radio Access protection is a non-3GPP access specific and outside the scope of the present document.
- **Network domain security (II):** the set of security features that enable nodes to securely exchange signaling data, and protect against attacks on the wireline network.
- **Non-3GPP domain security (III):** the set of security features are a non-3GPP access specific and outside the scope of the present document.
- **Application domain security (IV):** the set of security features that enable applications in the user and in the provider domain to securely exchange messages.
- **User domain security (V):** the set of security features that secure access to the mobile station. If the terminal does not support 3GPP access capabilities, 3GPP does not specify how user domain security is achieved.

4.2 Trusted non-3GPP Access

When all of the security feature groups are considered sufficiently secure by the home operator, the non-3GPP access is identified as a trusted non-3GPP access for that operator.

4.3 Untrusted non-3GPP Access

When one or more of the security feature groups is considered not sufficiently secure by the home operator, the non-3GPP access is identified as an untrusted non-3GPP access for that operator.

5 Security Features Provided by EPS for non-3GPP Accesses

5.1 User-to-Network security

5.1.1 User identity and device identity confidentiality

User identity confidentiality for procedures between the UE and the Evolved Packet Core is provided as defined in clauses 6, 8 and 9 of the present document.

The protection of user identity confidentiality at the non-3GPP access network level is outside the scope of 3GPP specifications.

Device identity confidentiality is outside the scope of 3GPP specifications.

5.1.2 Entity authentication

Entity authentication is provided as defined in clauses 6, 8 and 9 of the present document.

5.2 User data and signalling data confidentiality

Signaling data confidentiality between the UE and an entity in the Evolved Packet Core is provided as defined in clauses 6, 8 and 9 of the present document.

Optionally, user data confidentiality between the UE and the PDN GW is provided as defined in clause 9.2.2 of the present document when DS-MIPv6 is used,

The establishment of security contexts for user data and signaling data confidentiality between the UE and an entity in a non-3GPP access network is defined in clause 7 of the present document. The detailed definition of the corresponding confidentiality mechanisms is, however, outside the scope of 3GPP specifications.

Signaling data confidentiality between an entity in the non-3GPP access network and an entity in the Evolved Packet Core, or between two entities in the Evolved Packet Core, is provided as defined in clause 11 (Network Domain Security) of the present document.

User data and signaling data confidentiality between two entities in a non-3GPP access network is outside the scope of 3GPP specifications.

5.3 User data and signalling data integrity

Signaling data integrity between the UE and an entity in the Evolved Packet Core is provided as defined in clauses 6, 8 and 9 of the present document.

Optionally, user data integrity between the UE and the PDN GW is provided as defined in clause 9.2.2 of the present document when DS-MIPv6 is used,

The establishment of security contexts for user data and signaling data integrity between the UE and an entity in a non-3GPP access network is defined in clause 7 of the present document. The detailed definition of the corresponding integrity mechanisms is, however, outside the scope of 3GPP specifications.

Signaling data integrity between an entity in the non-3GPP access network and an entity in the Evolved Packet Core, or between two entities in the Evolved Packet Core, is provided as defined in clause 11 (Network Domain Security) of the present document.

User data and signaling data integrity between two entities in a non-3GPP access network is outside the scope of 3GPP specifications.

6 Authentication and key agreement procedures

6.1 General

Access authentication for non-3GPP access in EPS shall be based on EAP-AKA (RFC 4187 [7]) or on EAP-AKA' (RFC 5448 [23]). The EAP server for EAP-AKA and EAP-AKA' shall be the 3GPP AAA server residing in the EPC.

The UE and 3GPP AAA server shall implement both EAP-AKA and EAP-AKA'. It is specified in this specification in which cases EAP-AKA and EAP-AKA' respectively shall be used.

If the terminal supports 3GPP access capabilities, the credentials used with EAP-AKA and EAP-AKA' shall reside on the UICC.

If the terminal does not support 3GPP access capabilities, 3GPP does not specify where the credentials used with EAP-AKA and EAP-AKA' reside.

NOTE: EAP-AKA and EAP-AKA' may use the same credentials.

The procedure in clause 6.2 shall be performed whenever the procedure in clause 8 of the present document is not performed with the following exception:

- if the security procedure in clause 9.2.2.2 for DS-MIPv6 is performed over a trusted access network and
- if the trusted access network has the properties listed in clause 9.2.2.1

then the procedure in clause 6.2 may be skipped.

However, it is recommended to use the procedure in clause 6.2 unless another strong authentication and key establishment method is used, which is documented in a standard covering the non-3GPP access network.

NOTE 1: There are cases when the procedure in clause 6.2 cannot be performed due to lack of support for EAP in the access network. DSL-based access networks are examples of such access networks.

In cases where it is difficult to assess whether a given access network has the properties listed in clauses 9.2.2.1 and 9.3.1.2, it is strongly recommended to use the procedures for untrusted access in clause 8.

The HSS shall send an authentication vector with AMF separation bit = 1 (cf. TS 33.401 [16]) to a 3GPP AAA server as specified for the EAP-AKA' procedures defined in the present document. For authentication vectors with the "separation bit" set to 1, the secret keys CK and IK generated during AKA shall never leave the HSS, and shall not be used in a non-EPS context.

The non-3GPP access networks, which are trusted, can be pre-configured in the UE. The UE can e.g. have a list with non-3GPP access technologies, or access networks, or serving network operators that allow procedures for trusted non-3GPP IP access. Additionally, during 3GPP-based access authentication the UE may receive an indication whether the non-3GPP IP access is trusted or not. If such an indication is sent it shall be sent by the 3GPP AAA server as part of an EAP-AKA or EAP-AKA' request. If no such indication is received by the UE, and there is no pre-configured information in the UE, the UE shall consider the non-3GPP IP access as untrusted. In case of pre-configured information and indication received as part of an EAP-AKA or EAP-AKA' request are in conflict, the received indication shall take precedence.

NOTE 2: The protection mechanisms of EAP-AKA and EAP-AKA' prevent that an indication sent as part of an EAP-AKA request could be forged.

Additionally, in roaming situations the visited 3GPP network may send an indication about the trust status of the non-3GPP access network to the 3GPP AAA server. The 3GPP AAA server may take this indication from the visited network into account in its decision about sending a trust indication to the UE.

EAP-AKA and EAP-AKA' use pseudonyms and re-authentication identities. Pseudonyms and re-authentication identities should be generated using the method defined in TS 33.234 [9].

NOTE 3: When using the method in TS 33.234 [9] for the generation of pseudonyms and re-authentication identities the AAA server can resolve these identities without having to store them. In particular, they can be resolved even when the UE is not registered.

NOTE 4: TS 33.234 [9] defines Temporary Identities such that the leading six bits form the Temporary Identity Tag. This tag is converted to a printable character using the BASE64 method, according to TS 33.234 [9]. Compatibility with the NAI format defined in TS 23.003 [8] is achieved by choosing the temporary identity tag such that the printable character equals the leading digit for the NAI defined in TS 23.003.

6.2 Authentication and key agreement for trusted access

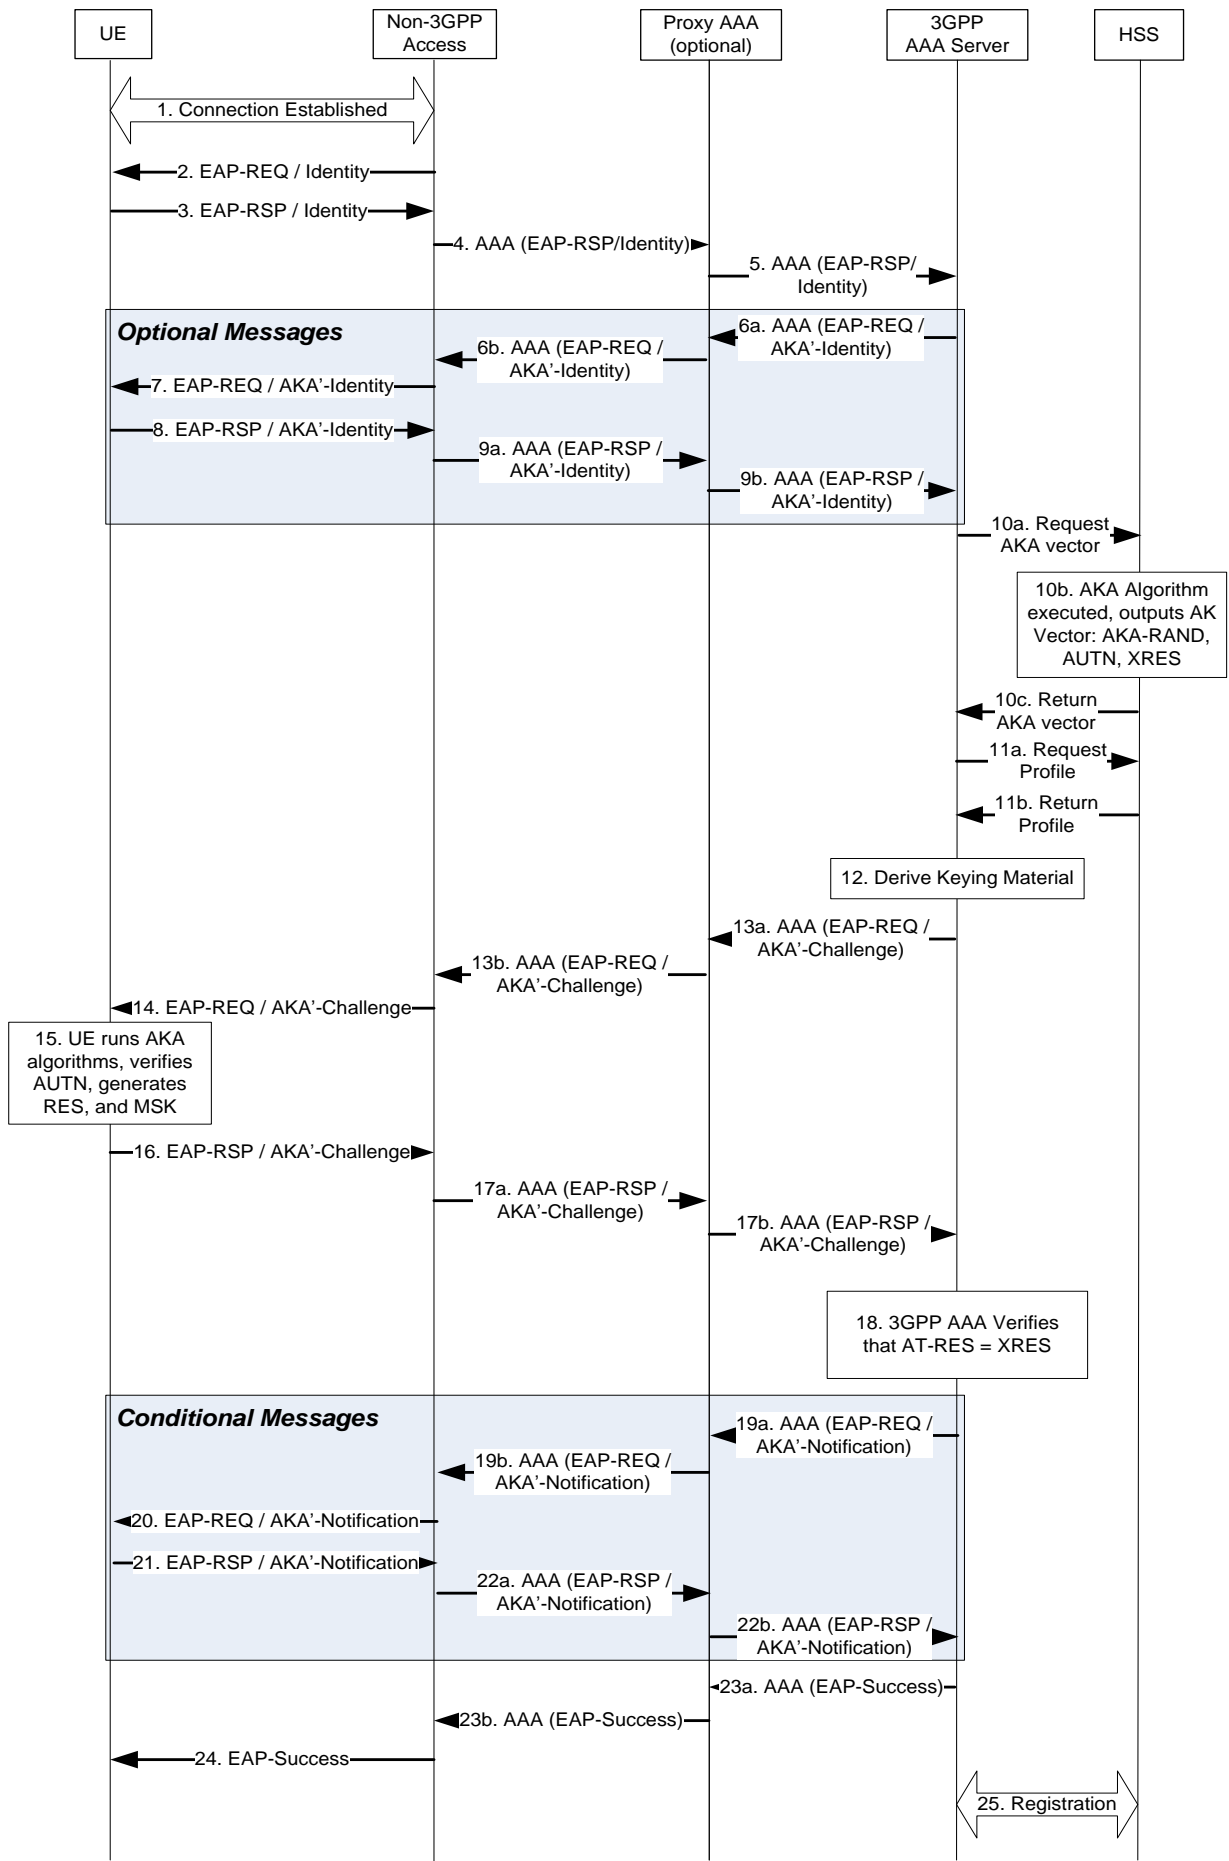

Figure 6.2-1: Non-3GPP Access Authentication

EAP-AKA' as defined in RFC 5448 [23] shall be used for mutual authentication and key agreement.

1. A connection is established between the UE and the trusted non-3GPP access network, using a procedure specific to the non-3GPP access network (which is out of scope for the present document).
2. The authenticator in the trusted non-3GPP access network sends an EAP Request/Identity to the UE.

NOTE 1: EAP packets are transported over this access network using a protocol specific to this access network (which is out of scope for the present document).

3. The UE sends an EAP Response/Identity message. The UE shall send its identity complying with Network Access Identifier (NAI) format specified in TS 23.003 [8]. NAI contains either a pseudonym allocated to the UE in a previous run of the authentication procedure or, in the case of first authentication, the IMSI. In the case of first authentication, the NAI shall indicate EAP-AKA' as specified in TS 23.003 [8].
4. The message is routed towards the proper 3GPP AAA Server based on the realm part of the NAI as specified in TS 23.003 [8]. The routing path may include one or several AAA proxies. The access type and the identity of the access network in which the authenticator resides, shall be included by the authenticator in the Diameter message. In the case of roaming, the visited network AAA proxy shall also include the visited network identifier in the same Diameter message.
The access network identity is defined separately for each access network type. For each access network type, the access network identity shall be documented in TS 24.302 [22] to ensure that UE and HSS use the same access network identities as input for key derivation.

NOTE 2: Diameter referral can also be applied to find the AAA server.

NOTE 3: The visited network identifier identifies a visited 3GPP network, and is to be distinguished from the access network identifier, which relates to a non-3GPP access network.

5. The 3GPP AAA Server receives the EAP Response/Identity message that contains the subscriber identity and the access type over the STa/SWd interface. In the case of roaming, the 3GPP AAA server also receives the visited network identifier in the same Diameter message that carried the EAP Response/Identity message.
6. The 3GPP AAA Server requests again the user identity, using the EAP Request/AKA' Identity message. This identity request is performed as the intermediate nodes may have changed or replaced the user identity received in the EAP Response Identity message, as specified in RFC 5448 [23]. However, in order to avoid this new request of the user identity, the home operator should ensure that the Authenticator and all AAA entities between the EAP peer and EAP server process the EAP-Response/Identity message inline with EAP-AKA' as specified in the present document and TS 23.003. Consequently, if the EAP server knows that the EAP-Response/Identity message was processed accordingly, the EAP server shall use the user identity which was received in the EAP-Response/Identity message in step 5 and skip this EAP Request/AKA' Identity request in steps 6 through 9.
7. The authenticator in the access network forwards the EAP Request/AKA' Identity message to the UE.
8. The UE responds with an identity that depends on the parameters contained in the EAP Request/AKA' Identity message; for details cf. TS 24.302 [22].
9. The authenticator in the access network forwards the EAP Response/AKA' Identity to the 3GPP AAA Server. The access type and the identity of the access network in which the authenticator resides, shall be included by the authenticator in this message. In the case of roaming, the visited network AAA proxy shall also include the visited network identifier in the same message. The identity received in this message will be used by the 3GPP AAA Server in the rest of the authentication process.
10. The 3GPP AAA Server shall identify the subscriber as a candidate for authentication with EAP-AKA', based on the received identity in the EAP-Response/Identity or EAP Request/AKA' Identity message. If the leading digits in the NAI do not indicate that the UE supports EAP-AKA', the 3GPP AAA server shall abort the authentication. If the UE does indicate that it supports EAP-AKA', the 3GPP AAA server then checks whether it has an unused authentication vector with AMF separation bit = 1 and the matching access network identifier available for that subscriber. If not, a set of new authentication vectors is retrieved from HSS. The 3GPP AAA server includes an indication that the authentication vector is for EAP-AKA', as defined RFC 5448 [23], and the

identity of the access network in which the authenticator resides in a message sent to the HSS. A mapping from the temporary identifier (pseudonym in the sense of RFC 4187 EAP-AKA [7]) to the IMSI is required.

NOTE 7a: As the UE moves around the access network identifier may change. But an authentication vector stored in the 3GPP AAA server can only be used if it is associated with the access network identifier of the current access network. This may make stored authentication vectors unusable. Furthermore, as the 3GPP AAA server resides in the home network there is no significant performance advantage in fetching batches of authentication vectors. It is therefore recommended that the 3GPP AAA server fetches only one authentication vector at a time.

Upon receiving from the 3GPP AAA server an indication that the authentication vector is for EAP-AKA' as defined in RFC 5448 [23], the HSS generates an authentication vector with AMF separation bit = 1. The HSS then transforms this authentication vector into a new authentication vector by computing CK' and IK' per Clauses A.1 and A.2 of the Normative Annex A with <access network identity> being one of the input parameters. The HSS then sends this transformed authentication vector to the 3GPP AAA server.

NOTE 7b: The 3GPP AAA server does not notice the transformation and treats this authentication vector like any other authentication vector.

The HSS and/or 3GPP AAA server need to ensure, based on local policy, that the non-3GPP access requesting the authentication data, which is identified by the information transmitted by the authenticator in step 4, is authorized to use the access network identity used to calculate CK' and IK'. The 3GPP AAA server shall have assurance of the origin of this information. The exact details of how to achieve this are not covered in this specification.

The HSS shall check if there is a 3GPP AAA Server already registered to serve for this subscriber. In case the HSS detects that another 3GPP AAA Server has already registered for this subscriber, it shall provide the current 3GPP AAA Server with the previously registered 3GPP AAA Server address. The authentication signalling is then routed to the previously registered 3GPP AAA Server with Diameter-specific mechanisms, e.g., the current 3GPP AAA Server transfers the previously registered 3GPP AAA Server address to the 3GPP AAA proxy or the AAA entity in the trusted non-3GPP access network, or the current 3GPP AAA Server acts as a AAA proxy and forwards the authentication message to the previously registered 3GPP AAA Server.

11. 3GPP AAA Server checks that it has the EPS access profile of the subscriber available. If not, the profile is retrieved from HSS. 3GPP AAA Server verifies that the subscriber is authorized to use the EPS.

NOTE 8: This step could be performed at some other point, after step 5 and before step 13.

12. New keying materials MSK and EMSK are derived from CK' and IK' according to RFC 5448 [23].

NOTE 9: The use of EMSK can refer to subclause 9.2.1 MIPv4.

A new pseudonym and/or re-authentication ID may be chosen and if chosen they shall be protected (i.e. encrypted and integrity protected) using keying material generated from EAP-AKA'.

13. The 3GPP AAA Server sends RAND, AUTN, a message authentication code (MAC) and two user identities (if they are generated), protected pseudonym and/or protected re-authentication id, to the authenticator in the access network in EAP Request/AKA'-Challenge message. The 3GPP AAA Server shall also include the access network identity in this message. The access network identity is defined in TS 24.302 [22]. The sending of the re-authentication id depends on 3GPP operator's policies on whether to allow fast re-authentication processes or not. It implies that, at any time, the 3GPP AAA Server decides (based on policies set by the operator) to include the re-authentication id or not, thus allowing or disallowing the triggering of the fast re-authentication process.

The 3GPP AAA Server may send as well a result indication to the authenticator in the access network, in order to indicate that it wishes to protect the success result message at the end of the process (if the outcome is successful). The protection of result messages depends on home operator's policies.

14. The authenticator in the access network sends the EAP Request/AKA'-Challenge message to the UE.

15. The UE first checks whether the AMF separation bit is set to 1. If this is not the case the UE shall reject the authentication. Otherwise, the UE runs AKA algorithms. The UE verifies that AUTN is correct and hereby authenticates the network. If AUTN is incorrect, the UE rejects the authentication (not shown in this example). If the sequence number is out of synch, the UE initiates a synchronization procedure, c.f. RFC 5448 [23]. If AUTN is correct, the UE computes RES, IK and CK.

The UE then computes CK' and IK' in the same way as the HSS, per Clauses A.1 and A.2 of the Normative Annex A with <access network identity> being one of the input parameters. The UE derives required additional new keying material, including the key MSK and EMSK, according to RFC 5448 [23] from the new computed CK', IK' and checks the received MAC with the new derived keying material.

If a protected pseudonym and/or re-authentication identity were received, then the UE stores the temporary identity(s) for future authentications.

The access network identity, which is input to key derivation to obtain CK', IK', shall be sent by the 3GPP AAA server in the EAP-request / AKA'-Challenge message as defined in RFC 5448 [23].

RFC 5448 [23] specifies a possibility for the UE to compare the access network identity received from the 3GPP AAA server with the access network identity received locally, e.g. from the link layer. It is defined in 3GPP TS 24.302 [22] for which access networks the comparison is done, how the UE shall determine the locally received network name and what the UE shall do if the check fails. If the comparison is done for a specific access network, it shall be done according to the rules specified in RFC 5448 [23]. The UE - or the human user - may use the network name as a basis for an authorization decision. E.g. the UE may compare the network name against a list of preferred or barred network names.

16. The UE calculates a new MAC value covering the EAP message with the new keying material. UE sends EAP Response/AKA'-Challenge containing calculated RES and the new calculated MAC value to the authenticator in the access network.

The UE shall include in this message the result indication if it supports such indications and if it received the same indication from the 3GPP AAA Server. Otherwise, the UE shall omit this indication.

17. The authenticator in the access network sends the EAP Response/AKA'-Challenge packet to 3GPP AAA Server.
18. The 3GPP AAA Server checks the received MAC and compares XRES to the received RES.
19. If all checks in step 18 are successful, the 3GPP AAA Server shall send the message EAP Request/AKA'-Notification, previous to the EAP Success message, if the 3GPP AAA Server and the UE have indicated the use of protected successful result indications as in RFC 5448 [23]. This message is MAC protected.

NOTE 11: Steps 19 to 22 are conditional based on the EAP Server and the UE having indicated the use of protected successful result indications.

20. The authenticator in the access network forwards the message to the UE.
21. The UE sends the EAP Response/AKA'-Notification.
22. The authenticator in the access network forwards the EAP Response/AKA'-Notification message to the 3GPP AAA Server. The 3GPP AAA Server shall ignore the contents of this message
23. The 3GPP AAA Server sends the EAP Success message to the authenticator in the access network (perhaps preceded by an EAP Notification, as explained in step 19). The 3GPP AAA Server also includes the key MSK, RFC 5448 [23], in the underlying AAA protocol message (i.e. not at the EAP level). The authenticator in the access network stores the keying material to be used in communication with the authenticated UE as required by the access network.
24. The authenticator in the access network informs the UE about the successful authentication with the EAP Success message. Now the EAP AKA' exchange has been successfully completed, and the UE and the authenticator in the access network share keying material derived during that exchange.
25. The 3GPP AAA Server shall initiate the registration to the HSS. The 3GPP AAA Server shall keep access session information related to the subscriber including the access network identity. The 3GPP AAA Server shall implement a policy to limit the number of active access sessions.

NOTE 12: It may happen in handover situations that, due to pre-registration, a subscriber is authenticated in a target access network while still being attached to the source access network.

NOTE 13: More detailed provisions may be required for particular access networks, similar to those in bullet 25 in TS 33.234 [9], subclause 6.1.1.1 for WLAN access networks.

The authentication process may fail at any moment, for example because of unsuccessful checking of MACs or no response from the UE after a network request. In that case, the EAP AKA' process will be terminated as specified in RFC 5448 [23] and an indication shall be sent to HSS.

6.3 Fast re-authentication procedure for trusted access

Fast re-authentication for EAP-AKA' is specified in RFC 5448 [23]. Fast re-authentication re-uses keys derived on the previous full authentication. Fast re-authentication does not involve the HSS nor the credentials used with EAP-AKA' (e.g. USIM application in case of terminal with 3GPP access capabilities), and does not involve the handling of AKA authentication vectors, which makes the procedure faster and reduces the load on the HSS and, in particular, the Authentication Centre.

UE and 3GPP AAA server shall implement fast re-authentication for EAP-AKA'. Its use is optional and depends on operator policy. If fast re-authentication for EAP-AKA' is used the 3GPP AAA server shall indicate this to the UE by means of sending the re-authentication identity to the UE as in step 13 of subclause 6.2.

The security level of fast re-authentication for EAP-AKA' is lower as it does not prove the presence of the credentials used with EAP-AKA' (e.g. presence of USIM application in case of terminal with 3GPP access capabilities) on the user side. The operator should take this into account when defining the policy on fast re-authentication.

Fast re-authentications for EAP-AKA' generates new keys MSK, which may be used for renewing session key used for protection in the non-3GPP access network.

The access network identity shall not change when going from the full to the fast re-authentication process. If this happens, the re-authentication process shall be terminated as defined in RFC 5448 [23].

In this section it is described how the process works for trusted non-3GPP access to EPS.

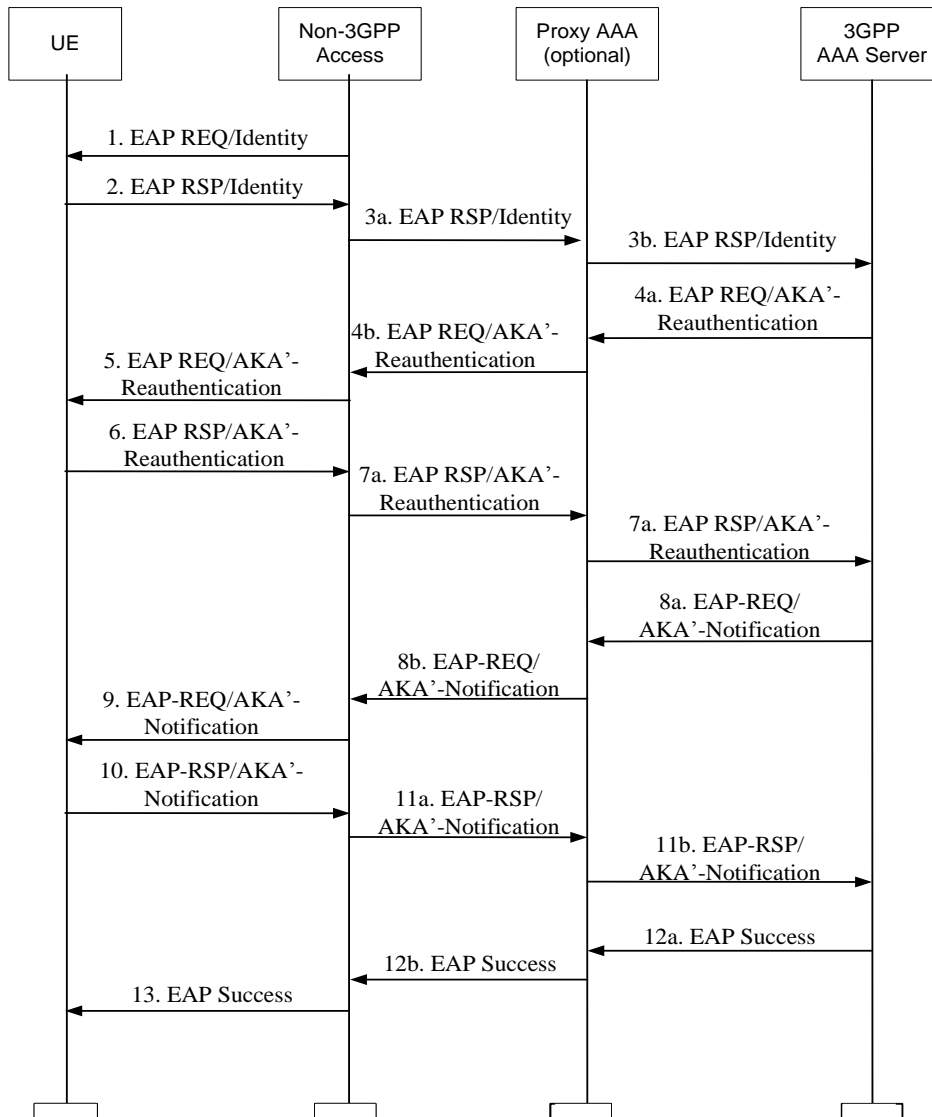

Figure 6.3-1: Non-3GPP Fast Re-authentication

1. Non-3GPP Access Network sends an EAP Request/Identity to the UE.
2. UE replies with an EAP Response/Identity containing a re-authentication identity (this identity was previously delivered by AAA server in a full authentication procedure).
3. The Non-3GPP Access Network forwards the EAP Response/Identity to the AAA server. Intermediate Proxy AAA's may perform routing and forwarding functions.
4. The AAA server initiates the Counter (which was initialized to one in the full authentication process) and sends it in the EAP Request message, together with the NONCE, the MAC (calculated over the NONCE) and a protected re-authentication ID for a next fast re-authentication. If the AAA server is not able to deliver a re-authentication identity, next time the UE shall force a full-authentication (to avoid the use of the re-authentication identity more than once).

The 3GPP AAA Server may send a result indication to the UE, in order to indicate that the success result message at the end of the process shall be protected (if the outcome is successful). The protection of result messages depends on home operator's policies.

The 3GPP AAA server may fail to recognize the identity as it may have been altered by proxies. In this case, the 3GPP AAA server may, as in the case of a full authentication, instead perform an EAP AKA' method specific identity request; i.e. "EAP-Request/AKA' identity [Any identity]" in order to obtain a more reliable identity, in analogy of step 7 of the full EAP AKA' authentication. This should however only be used in case the server fails to recognize the identity, as otherwise the purpose of fast re-authentication is defeated.

5. The Non-3GPP Access Network forwards the EAP Request message to the UE.
6. The UE verifies that the Counter value is fresh and the MAC is correct, and it sends the EAP Response message with the same Counter value (it is up to the AAA server to step it up) and a calculated MAC.

The UE shall include in this message the result indication if it received the same indication from the 3GPP AAA. Otherwise, the UE shall omit this indication.
7. The Non-3GPP Access Network forwards the response toward the AAA server.
8. The AAA server verifies that the Counter value is the same as it sent, and the MAC is correct, and sends the message EAP Request/AKA'-Notification, previous to the EAP Success message, if the 3GPP AAA Server requested previously to use protected success result indications. The message EAP Request/AKA'-Notification is MAC protected, and includes an encrypted copy the Counter used in the present re-authentication process.
9. The Non-3GPP Access Network forwards the EAP Request/AKA'-Notification message to the UE.
10. The UE sends the EAP Response/AKA'-Notification.
11. The Non-3GPP Access Network forwards the EAP Response/AKA'-Notification message toward the 3GPP AAA server. The 3GPP AAA Server shall ignore the contents of this message.
12. The AAA server sends an EAP Success message. If some extra keying material was generated for Access Network specific confidentiality and/or integrity protection, then the 3GPP AAA Server includes this derived keying material in the underlying AAA protocol message. (i.e., not at EAP level). The Non-3GPP Access Network stores the keying material which may be used in communication with the authenticated UE.
13. The EAP Success message is forwarded to the UE.

The re-authentication process may fail at any moment, for example because of unsuccessful checking of MACs or no response from the UE after a network request. In that case, the EAP AKA' process will be terminated as specified in RFC 5448 [23] and an indication shall be sent to HSS/HLR.

6.4 Authentication and key agreement for untrusted access

For untrusted access, UE and the ePDG shall perform mutual authentication during the IPsec tunnel establishment between the UE and the ePDG (SWu reference point). This procedure is specified in clause 8 of the present document.

In addition, before the IPsec tunnel establishment between the UE and the ePDG can be performed, the UE needs to obtain IP connectivity across the access network, which may require an access authentication, which is independent of the EAP-AKA authentication run in conjunction with the IPsec tunnel establishment. This additional access authentication and key agreement is not required for the security of the Evolved Packet Core. However, it may be required for the security of the untrusted non-3GPP access network. Any authentication and key agreement procedure deemed appropriate by the access network provider, including EAP-AKA', may be used.

7 Establishment of security contexts in the target access system

7.1 General assumptions

The following sub-clauses describe all the specifics that are related to the establishment of the security context of the non-3GPP target access for the purpose of Interworking with EPS system. The target access system may have other specifics that are used for the establishment of the security context while interworking with EPS system is not considered. These specifics are outside the scope of the present document.

7.2 Establishment of security context for Trusted non-3GPP Access

In this case, the credentials the UE shares with the 3GPP AAA server are used to establish security contexts in the access system.

It is assumed that the EPS user always uses EAP-AKA' credentials (e.g. a USIM application in case of terminal with 3GPP access capabilities) to perform mutual authentication and establish security contexts with the Home Network.

7.2.1 CDMA-2000 HRPD EPS Interworking

NOTE: General Concepts for Interworking between E-UTRAN and CDMA2000 are described in TS 23.402 [5] subclause 4.1.1.

7.2.1.1 EPS-HRPD Architecture

Figure 7.2.1.1-1 depicts the basic non-roaming architecture for HRPD-LTE Interworking.

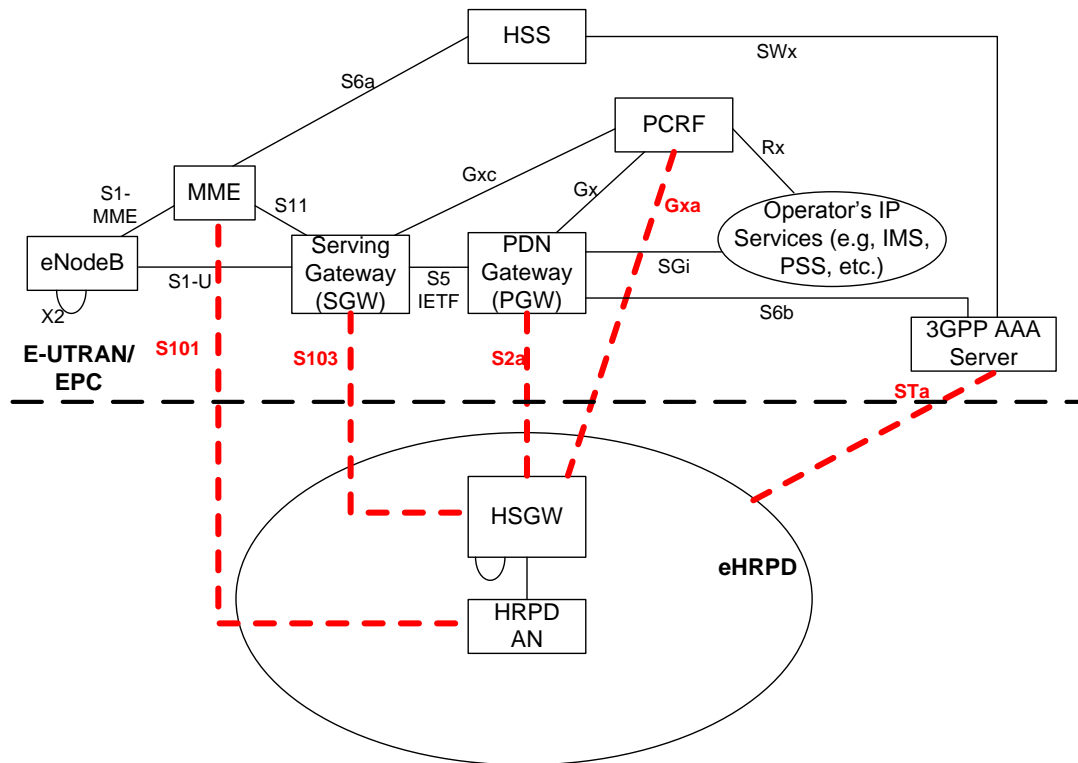

Figure 7.2.1.1-1: Basic non-roaming architecture for HRPD-LTE Interworking. Interworking reference points are highlighted.

7.2.1.2 Network Elements

7.2.1.2.1 E-UTRAN

E-UTRAN is described in detail in TS 36.300 [15] with additional functions listed in TS 23.401 [13].

7.2.1.2.2 MME

The details of the MME functionality are described in the TS 23.401 [13], while additional MME functionality, related to the interoperability with non-3GPP systems is described in the TS 23.402 [5].

The following are additional MME functions:

In the EPS, the security functions of the MME are described in TS 33.401 [16]. During the pre-registration towards the EPS from HRPD (as part of HRPD to EUTRAN HO), the procedures and functions are as defined in TS 33.401 [16], with the exception the NAS procedures will occur over S101. This is described in greater detail in clause 10.

7.2.1.2.3 Gateway

7.2.1.2.3.1 General

The functional split of PDN GW and Serving GW is described in TS 23.401 [13].

7.2.1.2.3.2 Serving GW

The details of the Serving GW functionality are described in the TS 23.401 [13], while additional Serving GW functionality, related to the interoperability with non-3GPP systems is described in the TS 23.402 [5].

7.2.1.2.3.3 PDN GW

The details of the PDN GW functionality are described in the TS 23.401 [13], while additional PDN GW functionality, related to the interoperability with non-3GPP systems is described in the TS 23.402 [5].

7.2.1.2.4 PCRF

The details of the PCRF functionality are described in the TS 23.401 [13] and TS 23.203 [14], while additional PCRF functionality, related to the roaming scenario is described in the TS 23.402 [5].

7.2.1.3 Reference Points

7.2.1.3.1 List of Reference Points

NOTE: S1-MME, S1-U, S2a, S2b, S2c, S3, S4, S5-MIP, S6a, Gx, S8, S9, S10, S11, S101, S103 are defined in TS 23.401 [13].

Additional reference points descriptions, related to the interoperability with non-3GPP systems are presented in the TS 23.402 [5].

7.2.1.3.2 Protocol assumptions

The protocol assumptions are described in the TS 23.402 [5].

NOTE: S103 is expected to be based on GRE, and as such does not involve any secure signalling to exchange GRE keys.

7.2.1.4 Security of the initial access to EPS via HRPD

EAP-AKA' access authentication shall be used according to section 6. As a result of EAP-AKA', the two keys, MSK and EMSK, are generated, cf. RFC 5448 [23].

In addition, according to subclause 6.2 of the present document, the 3GPP AAA Server sends the key MSK to the authenticator in the access network. The 3GPP AAA server shall retain the EMSK either until the subsequent EAP-AKA' authentication, or until it receives an indication that the current authenticated session is finished.

The security contexts in the HRPD access network may be based on keys derived from MSK. The HRPD access network is required to ensure that the identity of a user with whom a security context is established is securely tied to the identity of a user authenticated by EAP-AKA'.

The further details of the establishment of security contexts in the HRPD access network are outside the scope of the present document.

NOTE: Initial access to the EPS via HRPD is described in the TS 23.402 [5].

7.2.1.5 Security of handoff and pre-registration

NOTE: Security of handoff and pre-registration is described in the Section 10 of the present document.

7.2.2 WIMAX EPS Interworking

General Concepts for interworking between EPS and WIMAX are described in TS 23.402 [5]. Computation of mobility keys used for MIPv4 interworking with WiMAX access system is specified in clause 9.2.1

7.3 Establishment of security context between UE and untrusted non-3GPP Access

If authentication and key agreement procedure as described optional in subclause 6.4 is performed then also security contexts may be established between UE and non-3GPP access network. However, such additional establishment of security contexts is not required for the security of the Evolved Packet Core in the case of untrusted access.

8 Establishment of security between UE and ePDG

8.1 General

This section details the security mechanisms for procedures for untrusted Non-3GPP IP Accesses specified in TS 23.402 [5].

8.2 Mechanisms for the set up of UE-initiated IPsec tunnels

8.2.1 General

- The UE and the ePDG shall use IKEv2, as specified in RFC 4306 [3], in order to establish IPsec security associations.
- Public key signature based authentication with certificates, as specified in RFC 4306 [3], shall be used to authenticate the ePDG. The ePDG shall authenticate itself to the UE with an identity. This identity shall be the same as the FQDN of the ePDG determined by the ePDG selection procedures defined in TS 23.402 [5]. This identity shall be contained in the IKEv2 ID_FQDN payload and shall match a dNSName SubjectAltName component in the ePDG's certificate.
- EAP-AKA, as specified in RFC 4187 [7], within IKEv2, as specified in RFC 4306 [3], shall be used to authenticate UEs.
- For profile for IKEv2, IPsec ESP and certificate contents and processing refer to subclause 8.2.4.
- For the security aspects of emergency calls, cf. clause 13 of this specification.

8.2.2 Tunnel full authentication and authorization

The tunnel end point in the network is the ePDG. As part of the tunnel establishment attempt the use of a certain APN is requested. When a new attempt for tunnel establishment is performed by the UE the UE shall use IKEv2 as specified in RFC 4306 [3]. The authentication of the UE in its role as IKEv2 initiator terminates in the 3GPP AAA Server. The UE shall send EAP messages over IKEv2 to the ePDG. The ePDG shall extract the EAP messages received from the UE over IKEv2, and send them to the 3GPP AAA Server. The UE shall use the Configuration Payload of IKEv2 to obtain the Remote IP address.

The EAP-AKA message parameters and procedures regarding authentication are omitted. Only decisions and processes relevant to the use of EAP-AKA within IKEv2 are explained.

The message flow for the full authentication is depicted in the Figure 8.2.2-1.

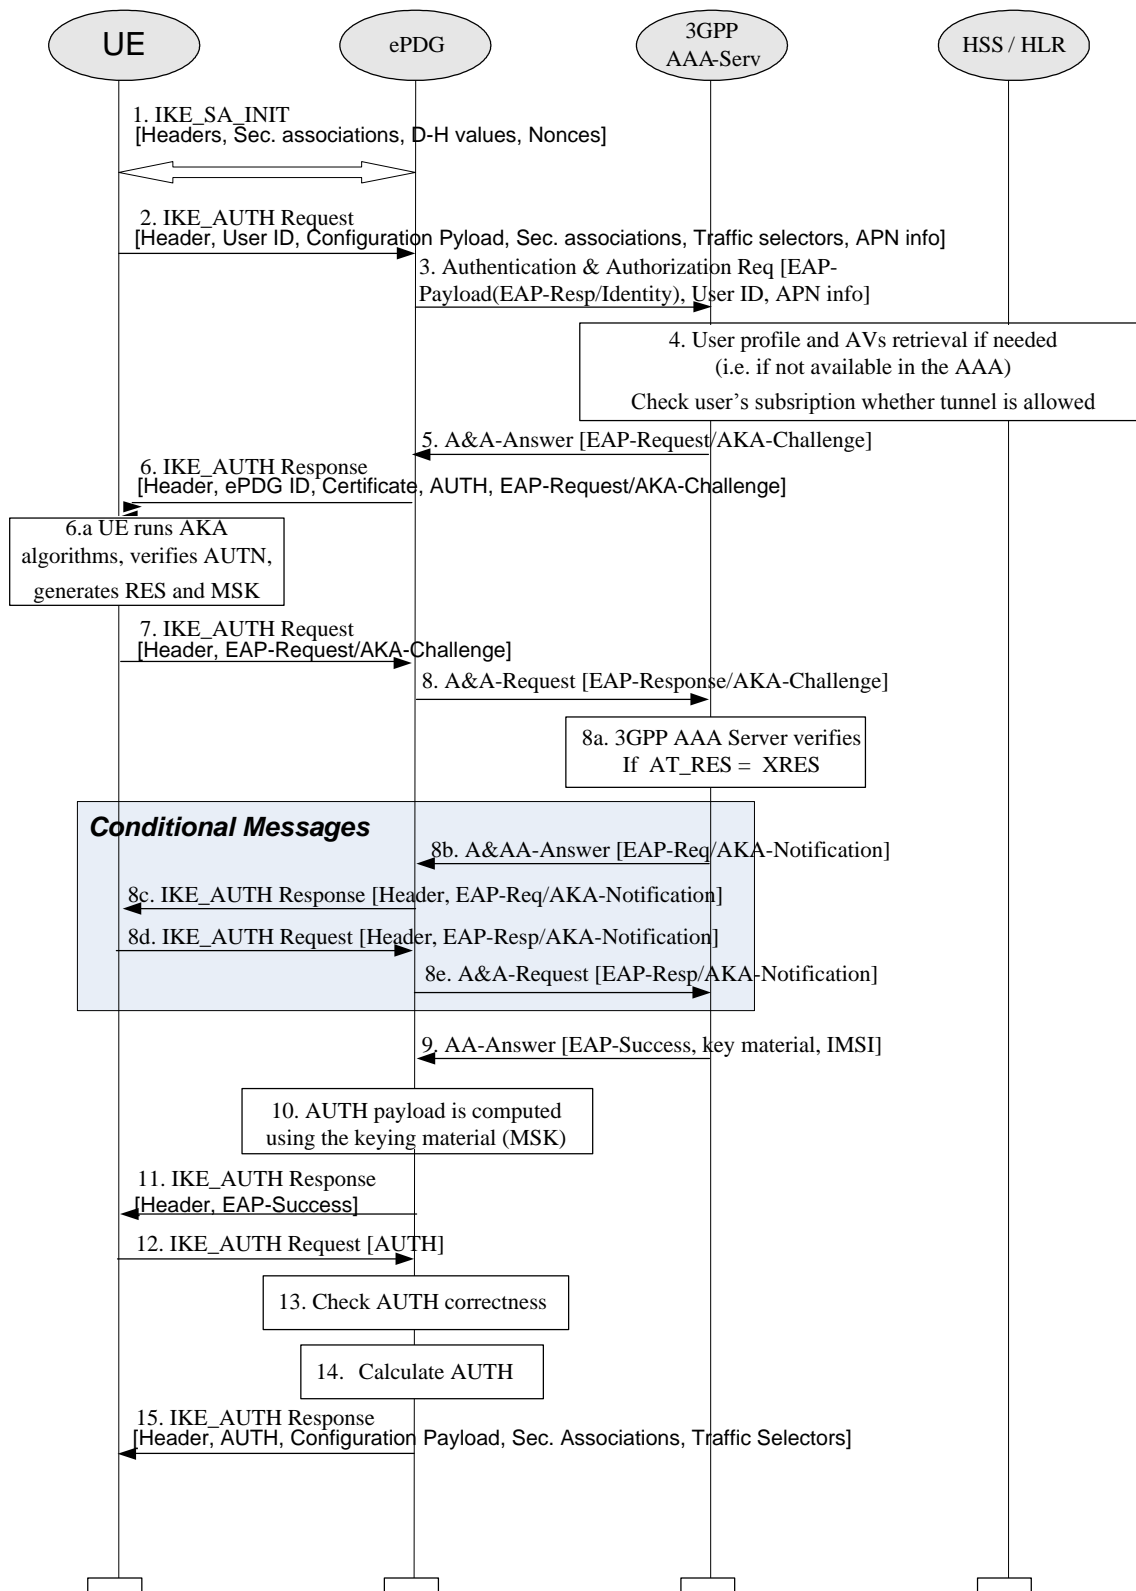

Figure 8.2.2-1: Tunnel full authentication and authorization

As the UE and ePDG generate nonces as input to derive the encryption and authentication keys in IKEv2, replay protection is provided. For this reason, there is no need for the 3GPP AAA Server to request the user identity again using the EAP-AKA specific methods (as specified in RFC 4187 [7]), because the 3GPP AAA Server is certain that no intermediate node has modified or changed the user identity.

1. The UE and the ePDG exchange the first pair of messages, known as IKE_SA_INIT, in which the ePDG and UE negotiate cryptographic algorithms, exchange nonces and perform a Diffie_Hellman exchange.

2. The UE sends the user identity (in the IDi payload) and the APN information (in the IDr payload) in this first message of the IKE_AUTH phase, and begins negotiation of child security associations. The UE omits the AUTH parameter in order to indicate to the ePDG that it wants to use EAP over IKEv2. The user identity shall be compliant with Network Access Identifier (NAI) format specified in TS 23.003 [8], containing the IMSI or the pseudonym, as defined for EAP-AKA in RFC 4187 [7]). The UE shall send the configuration payload (CFG_REQUEST) within the IKE_AUTH request message to obtain an IPv4 and/or IPV6 home IP Address and/or a Home Agent Address.
3. The ePDG sends the Authentication and Authorization Request message to the 3GPP AAA Server, containing the user identity and APN. The UE shall use the NAI as defined in accordance with clause 19.3 of 3GPP TS 23.003 [8], the 3GPP AAA server shall identify based on the realm part of the NAI that combined authentication and authorization is being performed for tunnel establishment with an ePDG which allows only EAP-AKA (and not an I-WLAN PDG as defined in TS 33.234 [9], which would allow also EAP-SIM). The different Diameter application IDs will help the 3GPP AAA Server distinguish among authentications for trusted access, as specified in clause 6 of the present document (which requires EAP-AKA' authentication), and authentications for tunnel setup in EPS (which allows only EAP-AKA).
4. The 3GPP AAA Server shall fetch the user profile and authentication vectors from HSS/HLR (if these parameters are not available in the 3GPP AAA Server). The 3GPP AAA Server shall lookup the IMSI of the authenticated user based on the received user identity (root NAI or pseudonym) and include the EAP-AKA as requested authentication method in the request sent to the HSS. The HSS shall then generate authentication vectors with AMF separation bit = 0 and send them back to the 3GPP AAA server.
The 3GPP AAA Server checks in user's subscription if he/she is authorized for non-3GPP access.
The counter of IKE SAs for that APN is stepped up. If the maximum number of IKE SAs for that APN is exceeded, the 3GPP AAA Server shall send an indication to the ePDG that established the oldest active IKE SA (it could be the same ePDG or a different one) to delete the oldest established IKE SA. The 3GPP AAA Server shall update accordingly the information of IKE SAs active for the APN.
5. The 3GPP AAA Server initiates the authentication challenge. The user identity is not requested again.
6. The ePDG responds with its identity, a certificate, and sends the AUTH parameter to protect the previous message it sent to the UE (in the IKE_SA_INIT exchange). It completes the negotiation of the child security associations as well. The EAP message received from the 3GPP AAA Server (EAP-Request/AKA-Challenge) is included in order to start the EAP procedure over IKEv2.
7. The UE checks the authentication parameters and responds to the authentication challenge. The only payload (apart from the header) in the IKEv2 message is the EAP message.
8. The ePDG forwards the EAP-Response/AKA-Challenge message to the 3GPP AAA Server.
 - 8.a The AAA checks, if the authentication response is correct.
 - 8.b-e If dynamic IP mobility selection is executed embedded to the authentication and authorization, the selected mobility mode is sent to the user in an AKA-Notification request, over Diameter A&A answer and IKE_AUTH message. The UE responds to this over IKEv2 and the ePDG forwards the response to the 3GPP AAA Server.
9. When all checks are successful, the 3GPP AAA Server sends the final Authentication and Authorization Answer (with a result code indicating success) including the relevant service authorization information, an EAP success and the key material to the ePDG. This key material shall consist of the MSK generated during the authentication process. When the SWm and SWd interfaces between ePDG and 3GPP AAA Server are implemented using Diameter, the MSK shall be encapsulated in the EAP-Master-Session-Key-AVP, as defined in RFC 4072 [10].
10. The MSK shall be used by the ePDG to generate the AUTH parameters in order to authenticate the IKE_SA_INIT phase messages, as specified for IKEv2 in RFC 4306 [3]. These two first messages had not been authenticated before as there was no key material available yet. According to RFC 4306 [3], the shared secret generated in an EAP exchange (the MSK), when used over IKEv2, shall be used to generate the AUTH parameters.
11. The EAP Success/Failure message is forwarded to the UE over IKEv2.
12. The UE shall take its own copy of the MSK as input to generate the AUTH parameter to authenticate the first IKE_SA_INIT message. The AUTH parameter is sent to the ePDG.

13. The ePDG checks the correctness of the AUTH received from the UE. At this point the UE is authenticated. In case S2b is used, PMIP signalling between ePDG and PDN GW can now start, as specified in TS 23.402 [5]. The ePDG continues with the next step in the procedure described here only after successful completion of the PMIP binding update procedure.
14. The ePDG calculates the AUTH parameter which authenticates the second IKE_SA_INIT message. The ePDG shall send the assigned Remote IP address in the configuration payload (CFG_REPLY).
- 15 The AUTH parameter is sent to the UE together with the configuration payload, security associations and the rest of the IKEv2 parameters and the IKEv2 negotiation terminates.

8.2.3 Tunnel fast re-authentication and authorization

Fast re-authentication for EAP-AKA is specified in RFC 4187 [7]. Fast re-authentication re-uses keys derived on the previous full authentication. Fast re-authentication does not involve the HSS nor the credentials used with EAP-AKA (e.g. USIM application in case of terminal with 3GPP access capabilities), and does not involve the handling of AKA authentication vectors, which makes the procedure faster and reduces the load on the HSS and, in particular, the Authentication Centre.

The UE and the 3GPP AAA server shall implement fast re-authentication for EAP-AKA. Its use is optional and depends on operator policy.

The security level of fast re-authentication for EAP-AKA is lower as it does not prove the presence of the credentials used with EAP-AKA (e.g. presence of USIM application in case of terminal with 3GPP access capabilities) on the user side. The operator should take this into account when defining the policy on fast re-authentication.

Fast re-authentications for EAP-AKA generates new keys MSK, which may be used for renewing session key used for protection in the non-3GPP access network.

The procedure is very similar to the tunnel full authentication and authorization. The only difference is that EAP fast re-authentication is used in this case.

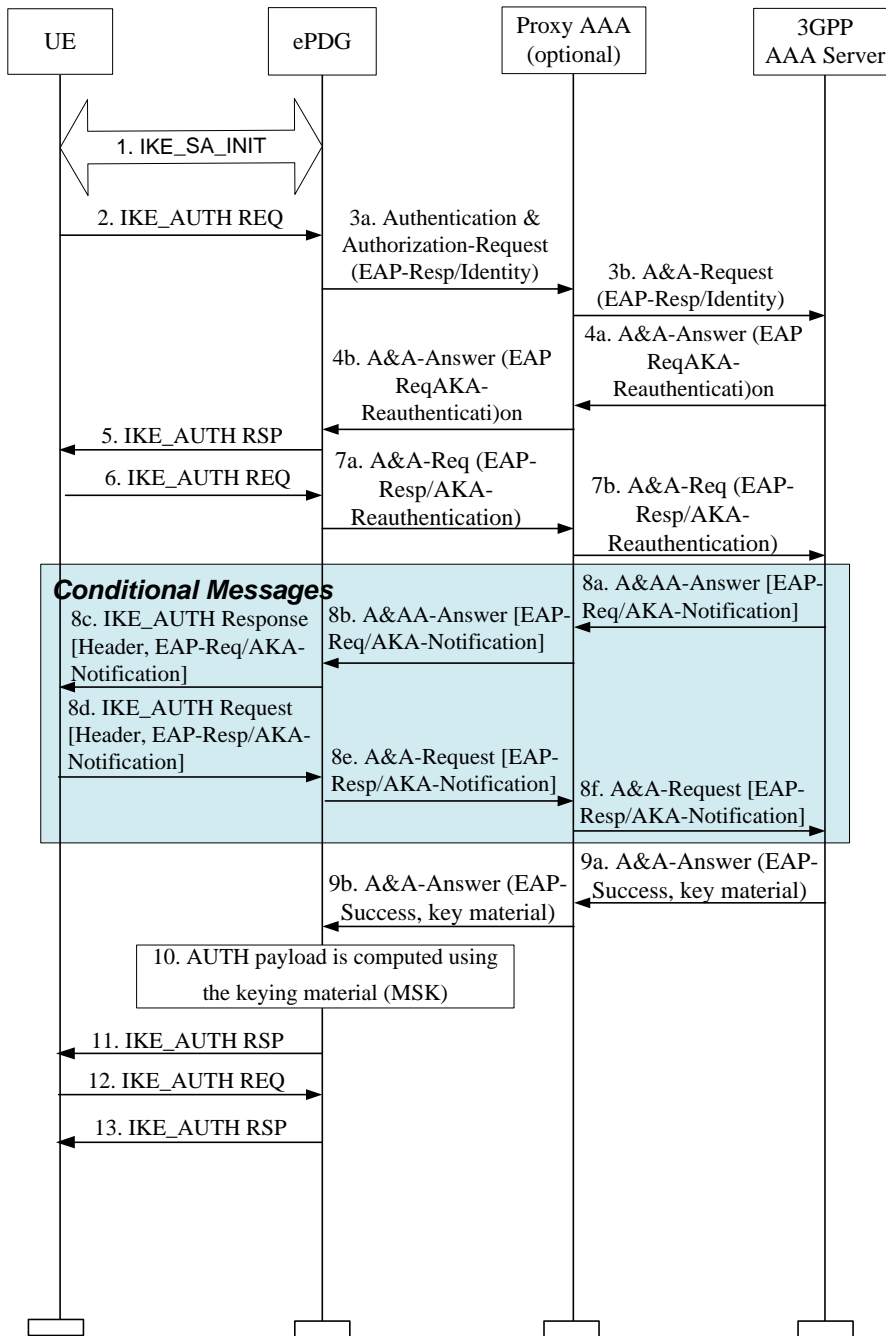

Figure 8.2.3-1: Untrusted Tunnel - Fast Re-authentication

1. The UE and the ePDG exchange the first pair of messages, known as **IKE_SA_INIT**, in which the ePDG and UE negotiate cryptographic algorithms, exchange nonces and perform a Diffie_Hellman exchange.
2. The UE sends the fast re-authentication identity (in the IDi payload) and the APN information (in the IDr payload) in this first message of the **IKE_AUTH** phase, and begins negotiation of child security associations. The UE omits the AUTH parameter in order to indicate to the ePDG that it wants to use EAP over IKEv2. The fast re-authentication identity used by the UE shall be the one received in the previous authentication process. If the UE's Remote IP address needs to be configured dynamically, then the UE shall send the configuration payload (**CFG_REQUEST**) within the **IKE_AUTH** request message to obtain a Remote IP Address.

3. The ePDG sends the Authentication and Authorization Request message with an EAP-Payload AVP toward the 3GPP AAA Server, containing the fast re-authentication identity. The UE shall use the fast-re-identity to create an NAI, as defined in clause 19.3 of 3GPP TS 23.003 [8]. The 3GPP AAA server shall identify based on the realm part of the NAI that the combined authentication and authorization is being performed for tunnel establishment with an ePDG (and not an I-WLAN PDG as defined in TS 33.234 [9] , which would allow also EAP-SIM). The different Diameter application IDs will help the 3GPP AAA Server distinguish among authentications for trusted access, as specified in clause 6 of the present document (which requires EAP-AKA' authentication), and authentications for tunnel setup in EPS (which allows only EAP-AKA).
4. The 3GPP AAA Server initiates the fast re-authentication challenge.
5. The ePDG sends an IKE_AUTH Response message to the UE, containing its identity, a certificate, and the AUTH parameter to protect the previous message it sent to the UE (in the IKE_SA_INIT exchange). It completes the negotiation of the child security associations as well. The EAP message (EAP-Request/AKA-Reauthentication) received from the 3GPP AAA Server is included in order to start the EAP procedure over IKEv2.
6. The UE checks the authentication parameters and responds to the fast re-authentication challenge. The only payload (apart from the header) in the IKEv2 message is the EAP message.
7. The ePDG forwards the EAP-Response/AKA-Reauthentication message toward the 3GPP AAA Server.
8. When all checks are successful, if dynamic IP mobility mode selection is executed during the tunnel setup, the selected IP mobility mode is sent via Diameter and IKEv2 signaling to the UE.
9. When all checks are successful, the 3GPP AAA Server sends the Authentication Answer including the user's IMSI, the relevant service authorization information, an EAP success and the key material toward the ePDG. This key material shall consist of the MSK generated during the fast re-authentication process. When the SWm interface (ePDG-AAA) is implemented using Diameter, the MSK shall be encapsulated in the EAP-Master-Session-Key AVP, as defined in RFC 4072 [10].
10. The MSK shall be used by the ePDG to generate the AUTH parameters in order to authenticate the IKE_SA_INIT phase messages, as specified in RFC 4306 [3]. These two first messages had not been authenticated before as there were no key material available yet. According to RFC 4306 [3], the shared secret generated in an EAP exchange (the MSK), when used over IKEv2, shall be used to generate the AUTH parameters.
11. The EAP Success message is forwarded to the UE over IKEv2.
12. The UE shall take its own copy of the MSK as input to generate the AUTH parameter to authenticate the first IKE_SA_INIT message. The AUTH parameter is sent to the ePDG.
13. The ePDG checks the correctness of the AUTH received from the UE and calculates the AUTH parameter which authenticates the second IKE_SA_INIT message. The ePDG shall send the assigned Remote IP address in the configuration payload (CFG_REPLY), if the UE requested for a Remote IP address through the CFG_REQUEST. Then the AUTH parameter is sent to the UE together with the configuration payload, security associations and the rest of the IKEv2 parameters and the IKEv2 negotiation terminates.

8.2.4 Security profiles

The profiles for IKEv2 and IPsec ESP as defined in TS 33.234 [9] shall be used.

For ePDG certificates, the certificate profiles as defined in TS 33.234 [9] shall be used.

8.2.5 Handling of IPsec tunnels in mobility events

8.2.5.1 General

The below sections describe the handling of IPsec tunnels in the idle and active mode mobility events when the target access has a UE and an ePDG, e.g. I-WLAN 3GPP IP Access System. In general, the IPsec tunnel handling during mobility events is managed by the end nodes where the IPsec tunnel is terminated, i.e. the UE and the ePDG.

In the case when the UE moves from the coverage area of the source ePDG and connect to another ePDG or a different access, the management of the IPsec tunnel between the UE and the source ePDG should be handled as follows:

1. The UE may keep all related IPsec tunnel security association parameters until its lifetime expires.
2. If after repeated attempts to contact the UE, the source ePDG concludes that the other endpoint (UE) has failed and all of its attempts have gone unanswered for a timeout period as specified in RFC 4306, the source ePDG may delete all the UE IPsec tunnel SA parameters.
3. If the source ePDG receives an indication from a trusted network element that the UE has moved outside its coverage area, e.g. 3GPP AAA server, the source ePDG can delete all of the UE IPsec tunnel security association parameters.

8.2.5.2 Idle mode mobility

When the UE moves from a source access where the UE is connected to an ePDG to a target access that involves the UE and the same ePDG, the UE shall use MOBIKE as per RFC 4555 [18] to update the ePDG with its new IP address. However, when the UE moves where the target access involves the UE and a different ePDG, the UE shall establish a new IPsec tunnel with the new ePDG as described in subclause 8.2.2.

On the other hand, if the UE is connected to EPS without being connected to an ePDG and then moves to a target access which involves the UE and an ePDG, the UE SHALL establish a new IPsec tunnel with the new ePDG as described in subclause 8.2.2.

8.2.5.3 Active mode mobility

When the UE moves from a source access where the UE is connected to an ePDG to a target access that involves the UE and the same ePDG, the UE shall use MOBIKE as per RFC 4555 [18] to update the ePDG with its new IP address. However, when the UE moves where the target access involves the UE and a different ePDG, the UE shall establish a new IPsec tunnel with the new ePDG as described in subclause 8.2.2.

On the other hand, if the UE is connected to EPS without being connected to an ePDG and then moves to a target access which involves the UE and an ePDG, the UE SHALL establish a new IPsec tunnel with the new ePDG as described in subclause 8.2.2.

9 Security for IP based mobility signalling

9.1 General

Clause 9.2 covers security for host based mobility and section 9.3 covers security for network based mobility.

9.2 Host based Mobility

9.2.1 MIPv4

9.2.1.1 General

MIPv4 FACoA and DSMIPv6 host based mobility protocols are supported over S2a and S2c interfaces respectively TS 23.402 [5].

The MIPv4 security is based on MIP Authentication extensions as defined in RFC 3344 [17]. The MIPv4 signalling messages shall be protected between the UE and the node acting as HA (i.e PDN GW) using MIP authentication extensions and optionally between the UE and the node acting as FA (non-3GPP access specific).

9.2.1.2 Bootstrapping of MIPv4 FACoA parameters

9.2.1.2.1 Procedures

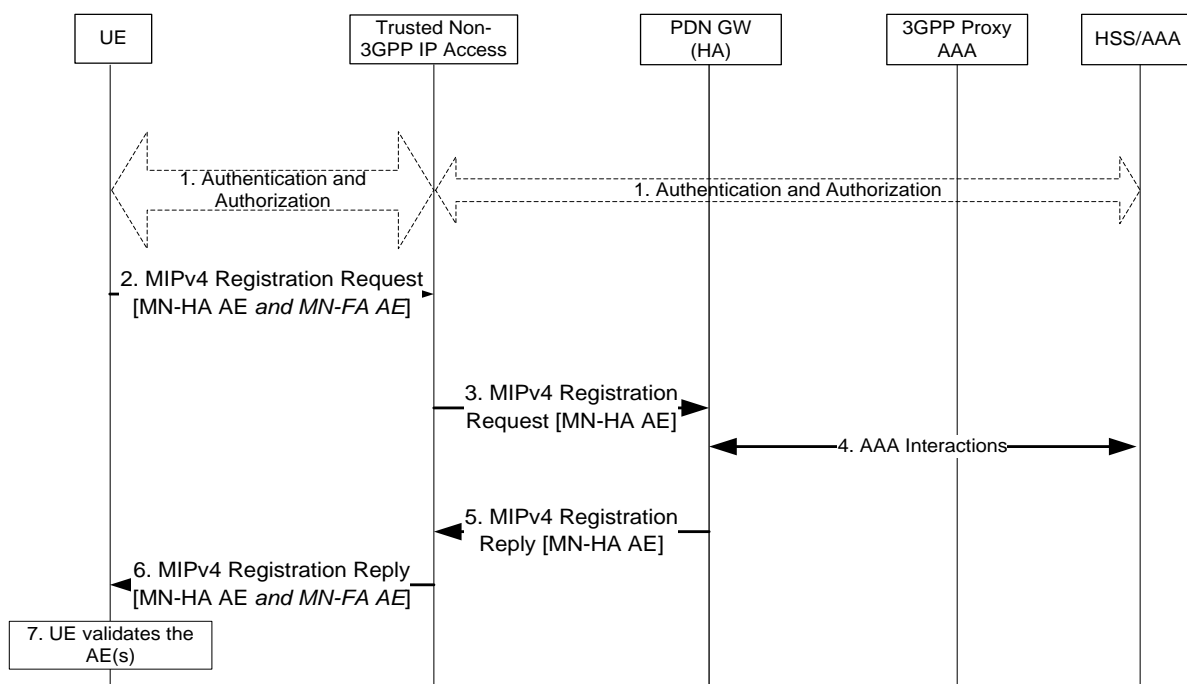

Figure 9.2.1.2.1-1: MIPv4 bootstrapping

The event that triggers Authentication and Authorization in step 1 between the Trusted Non-3GPP IP Access and the EAP Server, depends on the specific access technology cfr. TS 23.402 [5].

- 1) The Non-3GPP access specific authentication procedure based on EAP-AKA' is performed as specified in clause 6.2. Depending on the type of non-3GPP access system, the PDN GW address (HA address) may be determined

at this point. The details of this procedure and IPMM protocol selection procedure are specified in TS 23.402 [5]. If the network selects mobility management protocol as MIPv4 FACoA for the UE, then the UE and the EPC derive the keys required for MIPv4 bootstrapping.

The key EMSK that result from the EAP-AKA' authentication procedure is used to derive MIPv4 bootstrapping keys. Section 9.2.1.2.2 shows the derivation of MIPv4 bootstrapping keys in the UE and in the 3GPP AAA server and the key distribution from the 3GPP AAA server to the mobility agents. The trusted non-3GPP network receives a set of mobility keys and other keys in the Access-Accept message as a result of successful authentication.

- 2) The UE sends a Registration Request (RRQ) message to the FA as specified in TS 23.402 [5]. The UE includes the MN-HA Authentication Extension (AE) and optionally the MN-FA Authentication Extension (AE) as specified in RFC 3344 [17].
- 3) The FA processes the message according to RFC 3344 [17] and validates the MN-FA Authentication extension if present. The FA then forwards the RRQ message to the PDN GW. The RRQ message shall be protected between the FA and the PDN GW according to TS 33.210 [6].
- 4) The selected PDN GW obtains Authentication and Authorization information from the AAA/HSS.
- 5) The PDN GW validates the MN-HA authentication extension. After successful authentication extension validation, the PDN GW sends a Registration Reply (RRP) to the UE through the FA. The RRP message shall be protected between the PDN GW and the FA according to TS 33.210 [6].
- 6) The FA processes the RRP according to RFC 3344 [17]. The FA then forwards the RRP message to the UE. The FA includes the MN-FA authentication extension, if the FA received MN-FA authentication extension in the RRQ message.
- 7) The UE validates the MN-HA authentication extension and MN-FA authentication extension, if present.

9.2.1.2.2 MIPv4 Key Derivation

The Mobile IP Root Key (MIP-RK) is generated at the 3GPP AAA Server and the UE. The MIP-RK is generated from the EMSK according to RFC 5295[19] using the following formula:

$$\text{MIP-RK-1} = \text{HMAC-SHA256}(\text{EMSK}, \text{usage-data} \parallel 0x01)$$

$$\text{MIP-RK-2} = \text{HMAC-SHA256}(\text{EMSK}, \text{MIP-RK-1} \parallel \text{usage data} \parallel 0x02)$$

$$\text{MIP-RK} = \text{MIP-RK-1} \parallel \text{MIP-RK-2}$$

where:

usage-data = key label + "\0" + length

key label = miprk@wimaxforum.org in ASCII

length = 0x0200 the length in bits of the MIP-RK expressed as a 2 byte unsigned integer in network order

The length of the MIP-RK is 128 octets. The lifetime of MIP-RK is set to the lifetime of EMSK. The MIP-RK is stored in the 3GPP AAA Server. At the 3GPP AAA Server each user session is associated with a single MIP-RK. The MIP-RK is used to generate mobility keys. The MIPv4 keys are generated at the 3GPP AAA Server and at the UE. The keys generated at the 3GPP AAA Server are transported to the HA and the Authenticator in the trusted non-3GPP network by the use of the AAA protocol.

Security Parameter Indices (SPI) is generated from the MIP-RK as follows:

MIP-SPI = the 4 most significant bytes of HMAC-SHA256 (MIP-RK, "SPI CMIP PMIP "| APN))

SPI-CMIP4 = MIP-SPI,

Values MIP-SPI+1, MIP-SPI+2, and MIP-SPI+3 are reserved.

APN is used as an input parameter for deriving unique MIP-SPI, MN-HA key and MN-FA key per PDN connection. For default PDN connection, the UE does not provide an APN. In this case APN shall be omitted from the derivation of MIP-SPI, MN-HA key and MN-FA key.

The MIP-SPI and SPI-CMIP4 are derived at the UE and at the 3GPP AAA server.

The following procedure prevents collision between SPI values used for different Mobility keys, for example, mobility keys used by other access technologies, during the same Mobile IP session. The procedure SHALL be executed as follows:

- a. First, if the absolute value of the difference between the MIP-SPI and any currently active SPI is less than 4, the MIP-SPI value SHALL be incremented by FOUR until the current condition is satisfied.
- b. Next, if the MIP-SPI value is less than THREE smaller than the maximum possible value of SPI ($2^{32} - 1$), the MIP-SPI value SHALL be incremented by 259.
- c. Last, the process specified in Step 1 SHALL be applied again until the condition specified in Step 1 is satisfied.

The SPI value is used by the UE, HA, and 3GPP AAA server to identify the MN-HA key used to compute the MN-HA Authentication Extension in the RRQ message. In addition, MIP-SPI is distributed to the authenticator during Access Authentication, in AAA protocol attribute FA-RK-SPI, to identify the FA-RK key. FA-RK key and FA-RK-SPI will be used to further derive MN-FA key and MN-FA-SPI, to compute the MN-FA Authentication Extension in the RRQ message. When the lifetime of the MIP-RK expires the lifetime of the SPIs derived from it shall also expire.

The derivation of mobility key is given below:

$$\text{MN-HA} = \text{HMAC-SHA1}(\text{MIP-RK}, \text{"CMIP4 MN HA"} \mid \text{HA-IPv4} \mid \text{MN-NAI} \mid \text{APN})$$

The lifetime of all MN-HA keys shall be set to the lifetime of the MIP-RK. During the initial attach or additional PDN connectivity, the UE may not know the HA IP address. In this case, the UE use ALL-ZERO-ONE-ADDR [21] in the RRQ message to request for dynamic HA assignment. Under this case, the UE shall derive the MN-HA key using the ALL-ZERO-ONE-ADDR as the HA-IPv4 address and use this key for deriving MN-HA Authentication Extension and send in the RRQ. Then the HA informs this to the 3GPP AAA server in the AAA protocol message. In response from the 3GPP AAA server, the HA will receive RRQ-MN-HA-KEY that is calculated based on ALL-ZERO-ONE-ADDR address and also MN-HA key that is calculated based on HA IP address. The HA shall use the RRQ-MN-HA-KEY for validation of MN-HA Authentication Extension in the received RRQ. The HA then use MN-HA key for deriving RRP MN-HA Authentication Extension and sends the HA IP address as part of the RRP message. The UE shall recalculate the MN-HA key using the HA IP address received in the RRP and use this key for MN-HA Authentication Extension validation for the RRP. If the MN-HA authentication extension is valid, the new MN-HA key shall be in effect.

The derivation of FA-RK and MN-FA mobility keys are given below:

$$\text{FA-RK} = \text{HMAC-SHA1}(\text{MIP-RK}, \text{"FA-RK"})$$

$$\text{MN-FA} = \text{HMAC-SHA1}(\text{FA-RK}, \text{"MN FA"} \mid \text{FA-IP} \mid \text{MN-NAI} \mid \text{APN})$$

The FA-RK is generated by the 3GPP AAA Server and distributed to the Authenticator. It is used by the Authenticator to derive MN-FA keys as requested by the FA. The MN-FA key is derived based on the FA-IP address to separate keys between different FAs for the same authentication session. The lifetime of FA-RK and MN-FA shall be set to the lifetime of the MIP-RK. The SPI associated with the MN-FA (MN-FA-SPI) is set to the same value of FA-RK-SPI distributed during Access Authentication.

During EAP-Re-authentication, the 3GPP AAA server and the UE generate new MIP-RK, SPI, MN-HA and FA-RK. The old MIP-RK and its derivatives (MN-HA, FA-RK, MN-FA) shall be deprecated after confirming that the newly generated mobility keys in the 3GPP AAA server and the UE are the same. Upon receipt of an MIP-RRQ from the UE, the HA shall determine whether re-authentication has occurred since the last MIP-RRQ by comparing the SPI contained in the MN-HA Authentication extension of the received MIP-RRQ to the locally stored value. If the two SPIs are different, the HA shall assume that re-authentication has occurred, and the new MN-HA key shall be retrieved from the 3GPP AAA server. After verifying the MIP-RRQ message with the new MN-HA key and creating the MIP-RRP Authentication Extension, the HA deprecate the old key. The UE shall deprecate the old key, once it successfully verifies the MIP-RRP using the new key.

9.2.1.2.3 Key Usage

Key	Generated by	Used at
MN-HA	UE and 3GPP AAA server	HA and UE
FA-RK	UE and 3GPP AAA server	UE and Authenticator
MN-FA	UE and Authenticator	FA and UE

The keys that are used by the UE are generated by the UE and shall not be transported outside the UE. The keys generated by the 3GPP AAA Server are transported to the HA or the Authenticator using AAA protocols.

9.2.1.2.4 Key Distribution for MIPv4

In this section, key distribution for MIPv4 is described. Two scenarios are possible, where in the first scenario Authenticator and FA are co-located and in the case of FA relocation, also the Authenticator changes based on EAP re-authentication. In the second scenario, no re-authentication takes place when the FA is relocated, so the anchor Authenticator is continued to be used, and provisions the new FA with the required mobility keys. However key handling between Authenticator and FA is out of scope of the present document.

The Authenticator receives FA_RK in the RADIUS/DIAMETER Access-Accept message as a result of successful authentication. The keys are stored at the authenticator.

The 3GPP AAA Server distributes the MN-HA key, if requested, to the HA using RADIUS/DIAMETER Access-Accept.

9.2.2 DS-MIPv6

9.2.2.1 General

The DS-MIPv6 security is based on IPsec as defined in RFC4877 [2]. The IPsec security association is established between the UE and the node acting as HA (i.e. PDN GW).

The following principles apply:

- The UE and the HA shall use IKEv2, as specified in RFC4306, in order to establish IPsec security associations.
- Public key signature based authentication with certificates, as specified in RFC 4306 [3], is used to authenticate the HA. The HA shall authenticate itself to the UE with an identity. This identity shall be the same as the FQDN of the HA if the HA is found via DNS cfr. TS 23.402 [5].
- EAP-AKA, as specified in RFC 4187 [7], within IKEv2, as specified in RFC4877 [2] and RFC 4306 [3], is used to authenticate UEs.

The following properties are needed to provide secure S2c over a Trusted Non-3GPP Access:

- The Trusted Access will authenticate the UE and provide a secure link for the data to be transferred from the UE to the Trusted Access.
- The Trusted Access protects against source IP address spoofing.
- The Trusted Access and PDN GW will have a secure link between them to transfer the user's data across.
- The Trusted Access and EPC need to co-ordinate when the UE detaches from the Trusted Access in order to ensure that the IP address that was assigned to the UE is not be used by another UE without EPC being aware of the change (i.e. enable the PDN GW to remove the CoA address binding for the old UE).

These properties ensure that the traffic the PDN GW is receiving has originated at the UE while UE is attached to the Trusted Access. These properties may be provided using enhanced security mechanisms defined in clause 9.2.2.4.

NOTE 1: If Trusted Access and EPC do not co-ordinate regarding UE detachment then the UE that was re-assigned the IP address would be capable of impersonating traffic until the binding in PDN GW timed out. NOTE 2: Procedures internal to the Trusted Access are outside the scope of the present document.

The allocation of IP addresses in the access network may provide the last property listed above. If the IP address is not re-allocated until after the MIP Binding has expired or IKE Dead Peer Detection has been run. This means that the PDN

GW will no longer associate the old UE to the IP address once the new UE gets the IP address and hence there is no risk of impersonation attacks.

PCC may also be used to provide the last property listed above in access networks that support it. In the case that PCC is used, a GW control session is established between the Trusted Access and the PCRF. This GW control session is identified by the UE ID and the IP address allocated to the UE (i.e. CoA if DSMIPv6 is used). Using the GW control session, the UE is restricted to limited access; in particular, the Trusted Access restricts the forwarding of the packets only to IKEv2 and BU messages until the binding at the PDN GW is established. The Trusted Access knows when the binding is established at the PDN GW because it receives an update of the GW control session. The flows for this control of policy are given in section(s) 6.3 and 6.6.2 of TS 23.402. This prevents a UE that attaches to the Trusted Access from sending non-signalling traffic to the PDN GW until it has completed a BU with the PDN GW and prevents an impersonation attack.

9.2.2.2 Bootstrapping of DSMIPv6 parameters

9.2.2.2.1 Full Authentication and authorization

The first procedure that must be performed by the MN is the discovery of the HA address, which in case of EPS is the IP address of the PDN GW. The detailed of this procedure are specified in TS 23.402 [5] and TS 24.303 [20].

As soon as the Mobile Node has discovered the PDN GW address, it establishes an IPsec Security Association with the Home Agent itself through IKEv2. The detailed description of this procedure is provided in RFC4877 [2]. The IKEv2 Mobile Node to Home Agent authentication is performed using Extensible Authentication Protocol (EAP).

When the Mobile Node runs IKEv2 with its Home Agent, it shall request an IPv6 Home Network Prefix through the Configuration Payload in the IKE_AUTH exchange by including an MIP6_HOME_PREFIX attribute.

When the Home Agent processes the message, it allocates a Home Network Prefix and sends it a CFG_REPLY message. The UE shall then auto-configure a Home Address from the IPv6 prefix received from the HA.

The IPv6 Home Network Prefix allocation through IKEv2 allows to bind the Home Address with the IPsec security association so that the MN can only send Binding Updates for its own Home Address and not for other MN's Home Addresses.

Figure 9.2.2.2.1-1 provides the flow for the initial DS-MIPv6 bootstrapping, focusing on the security aspects of the flow.

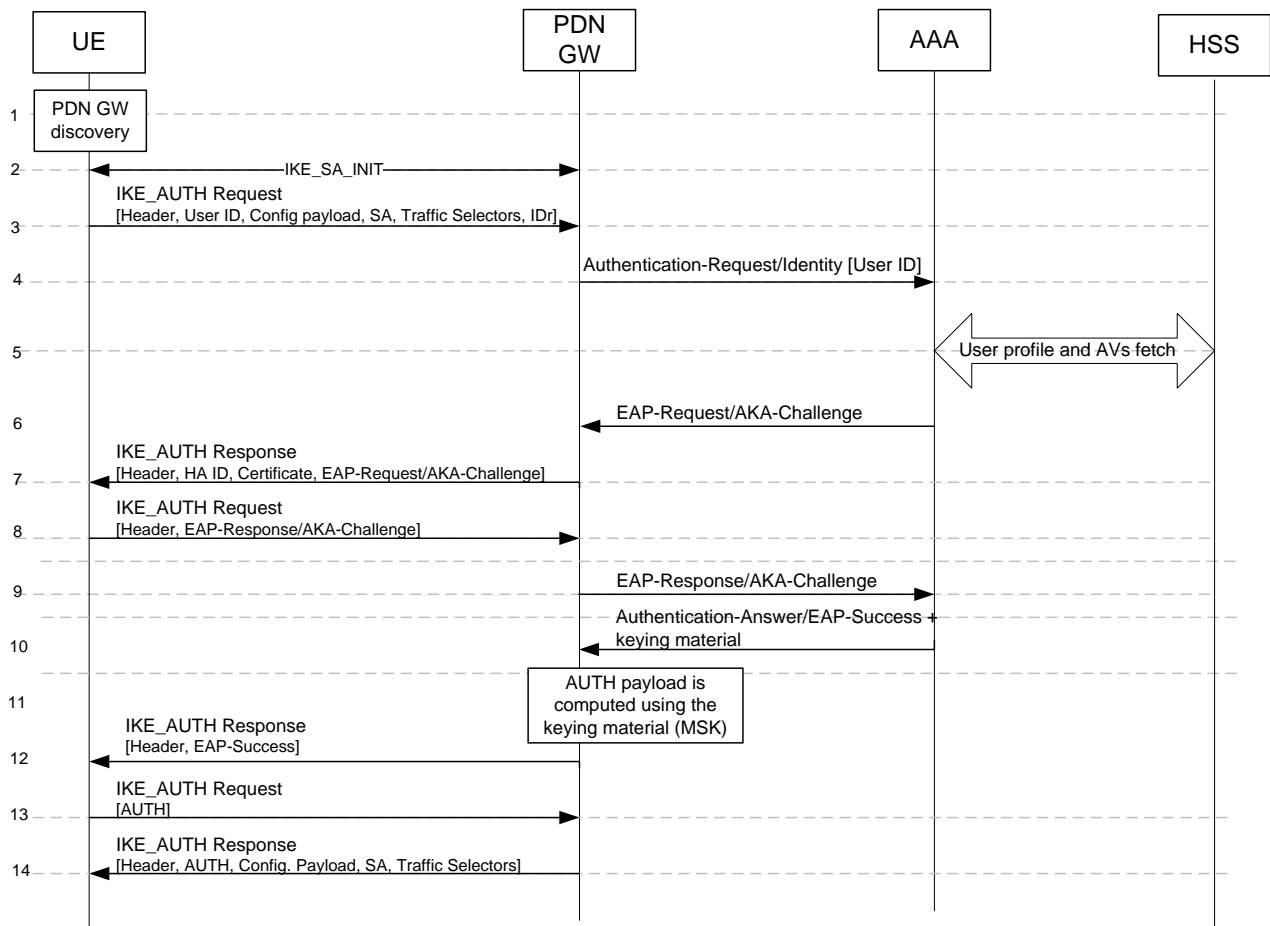

Figure 9.2.2.1-1: DS-MIPv6 bootstrapping based on IKEv2

- 1) The UE discovers the PDN GW address based on the procedure specified in TS 23.402 [5].
- 2) The UE starts an IKEv2 exchange with the PDN GW. The first part of this exchange is an IKE_SA_INIT exchange. In this phase the PDN GW and UE negotiate cryptographic algorithms, exchange nonces and perform a Diffie-Hellman exchange.
- 3) The UE sends the user identity (in the IDi payload) and the APN identifier (in the IDr payload) in this first message of the IKE_AUTH phase, and begins negotiation of child security associations. The UE omits the AUTH parameter in order to indicate to the PDN GW that it wants to use EAP over IKEv2. The user identity shall be compliant with Network Access Identifier (NAI) format specified in TS 23.003 [8], containing the IMSI or the pseudonym, as defined for EAP-AKA in RFC 4187 [7]). The UE shall send the configuration payload (CFG_REQUEST) within the IKE_AUTH request message to obtain an IPv6 Home Network Prefix as specified in 3GPP TS 24.303 [20]. The UE shall include the Traffic Selectors to protect DS-MIPv6 signalling as specified in RFC4877 [2].
- 4) The PDN GW sends the Authentication Request message with an EAP AVP to the 3GPP AAA Server, containing the user identity, APN and a parameter indicating that the authentication is being performed for DS-MIPv6 security. For the communication between PDN GW and 3GPP AAA server, cf. also [4].
- 5) The 3GPP AAA Server shall fetch the user profile and authentication vectors from HSS/HLR (if these parameters are not available in the 3GPP AAA Server). The 3GPP AAA Server shall include the parameter received in step 4 indicating that the authentication is being performed for DSMIPv6 in the request to the HSS. The HSS shall then generate authentication vectors with AMF separation bit = 0 and send them back to the 3GPP AAA server. The AAA checks that the UE is authorised to use the APN.
- 6) Based on the identity received, the 3GPP AAA server selects an Authentication Vector (RAND, AUTN, CK, IK, XRES) for the UE. The 3GPP AAA Server then initiates the authentication challenge by sending the EAP-Request/AKA-Challenge containing RAND and AUTN as described by RFC 4187 [7]. The user identity is not requested again, as in a normal authentication process, because there is the certainty that the user identity received in the EAP Identity Response message has not been modified or replaced by any intermediate node.

The reason is that the user identity was received via an IKEv2 secure channel which can only be decrypted and authenticated by the end points (the PDN GW and the UE).

- 7) The PDN GW responds to the UE with its identity, a certificate, and sends the AUTH parameter to protect the previous message it sent to the UE (in the IKE_SA_INIT exchange). The EAP message received from the 3GPP AAA Server (EAP-Request/AKA-Challenge), which contains RAND and AUTN, is included in order to start the EAP procedure over IKEv2.
- 8) The UE checks whether the AUTN is correct [11] and if so calculates CK, IK and RES and passes these to the UE. The UE checks the IKE authentication parameters and responds to the authentication challenge. The only payload (apart from the header) in the IKEv2 message is the EAP message which contains the AKA response, RES.
- 9) The PDN GW forwards the EAP-Response/AKA-Challenge message to the 3GPP AAA Server.
- 10) The 3GPP AAA Server checks the EAP message including that RES = XRES and then calculates MSK from CK and IK as described in RFC 4187 [7]. The 3GPP AAA Server sends the Authentication Answer including an EAP success and the key material to the PDN GW. This key material shall consist of the MSK generated during the authentication process. In case of PDN GW reallocation upon attach on S2c, the AAA shall include the target PDN GW's identity as specified in 3GPP TS 23.402 [5].

The 3GPP AAA Server steps up the counter of IKE SAs for that APN. If the maximum number of IKE SAs for that APN is exceeded, the 3GPP AAA Server shall send an indication to the PDN GW that established the oldest active IKE SA (it could be the same PDN GW or a different one) to delete the oldest established IKE SA. The 3GPP AAA Server shall update accordingly the information of IKE SAs active for the APN.

- 11) The AUTH payload is computed using the received MSK.
- 12) The EAP Success message is forwarded to the UE over IKEv2.
- 13) The UE also generates MSK as input to generate the AUTH parameter to authenticate the first IKE_SA_INIT message. The AUTH parameter is sent to the PDN GW.
- 14) The PDN GW checks the correctness of the AUTH received from the UE and calculates the AUTH parameter which authenticates the second IKE_SA_INIT message. The PDN GW shall send the assigned Home Network prefix in the configuration payload (CFG_REPLY) as specified in 3GPP TS 24.303 [20], except in the case of PDN GW reallocation upon attach on S2c, when the PDN GW shall send to the UE the target PDN GW's address as specified in 3GPP TS 23.402 [5]. Then the AUTH parameter is sent to the UE together with the configuration payload, security associations and the rest of the IKEv2 parameters and the IKEv2 negotiation terminates.

In the case PDN GW reallocation, the UE shall begin a new DSMIPv6 bootstrapping with the target PDN GW.

9.2.2.2.2 Fast re-authentication and authorization

Fast re-authentication for EAP-AKA is specified in RFC 4187 [7]. Fast re-authentication re-uses keys derived on the previous full authentication. Fast re-authentication does not involve the HSS nor the credentials used with EAP-AKA (e.g. USIM application in case of terminal with 3GPP access capabilities), and does not involve the handling of AKA authentication vectors, which makes the procedure faster and reduces the load on the HSS and, in particular, the Authentication Centre.

The UE and the 3GPP AAA server shall implement fast re-authentication for the use of EAP-AKA with DSMIPv6. Its use is optional and depends on operator policy.

The security level of fast re-authentication for EAP-AKA is lower as it does not prove the presence of the EAP-AKA credentials (e.g. USIM application in case of terminal with 3GPP access capabilities) on the user side. The operator should take this into account when defining the policy on fast re-authentication.

Fast re-authentications for EAP-AKA generates new keys MSK, which may be used for renewing session key used for protection in the non-3GPP access network.

The procedure is very similar to the tunnel full authentication and authorization. The only difference is that EAP fast re-authentication is used in this case.

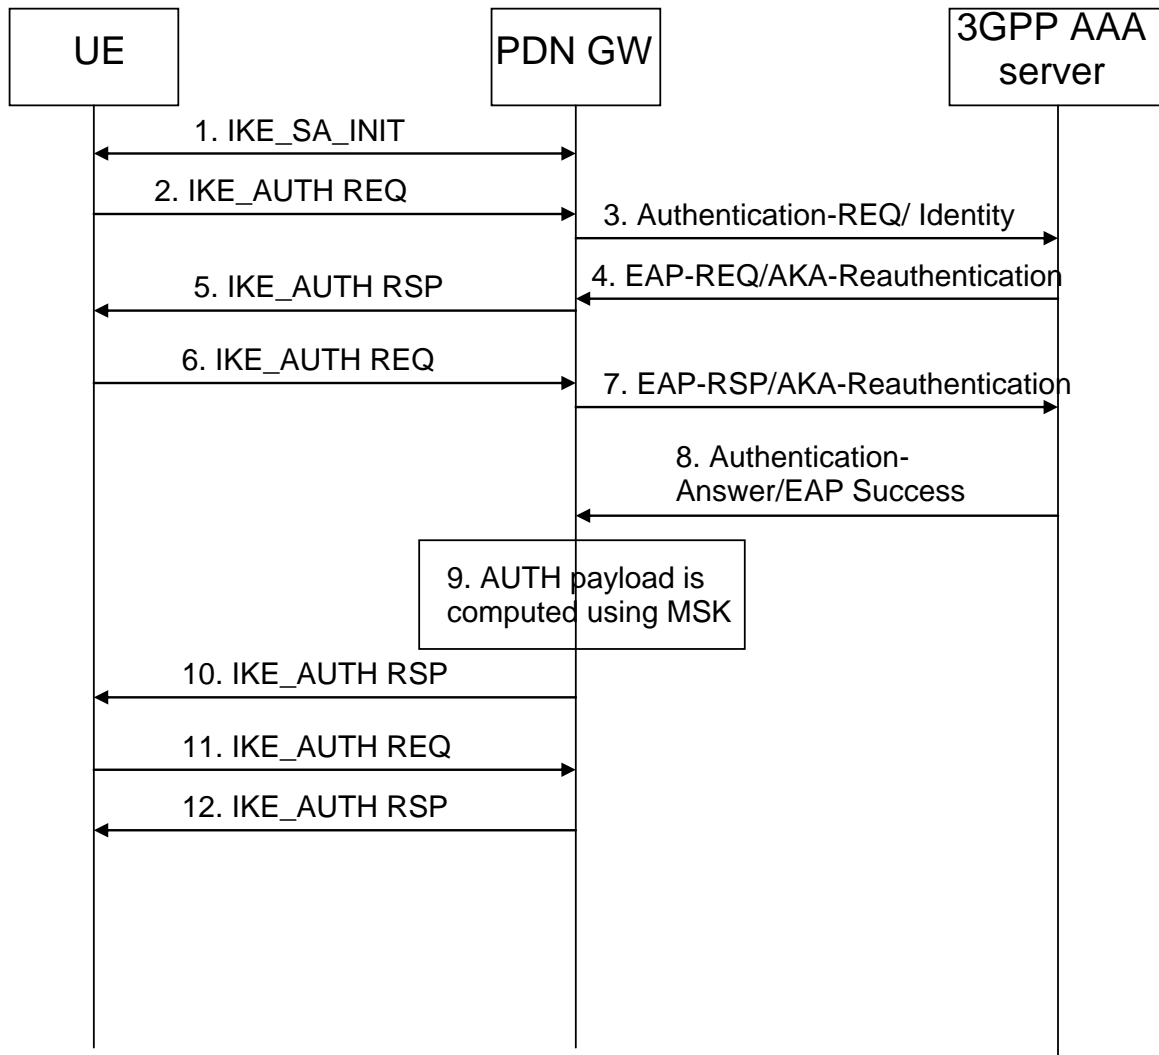

Figure 9.2.2.2-1: Fast Re-authentication for DSMIPv6

1. The UE and the PDN GW exchange the first pair of messages, known as IKE_SA_INIT, in which the PDN GW and UE negotiate cryptographic algorithms, exchange nonces and perform a Diffie_Hellman exchange.
2. The UE sends the re-authentication identity (in the IDi payload) and the APN information (in the IDr payload) in this first message of the IKE_AUTH phase, and begins negotiation of child security associations. The UE omits the AUTH parameter in order to indicate to the PDN GW that it wants to use EAP over IKEv2. The re-authentication identity used by the UE shall be the one received in the previous authentication process. If the UE's Remote IP address needs to be configured dynamically, then the UE shall send the configuration payload (CFG_REQUEST) within the IKE_AUTH request message to obtain a Remote IP Address.
3. The PDN GW sends the Authentication Request message with an EAP AVP toward the 3GPP AAA Server, containing the re-authentication identity. The PDN GW shall include the APN and a parameter indicating that the authentication is being performed for DSMIPv6 with a PDN GW. This will help the 3GPP AAA Server distinguish among authentications for DSMIPv6, trusted access, as specified in clause 6 of the present document, authentications for tunnel setup in I-WLAN (which would allow also EAP-SIM) and authentications for tunnel setup in EPS (which allow only EAP-AKA). The AAA checks that the UE is authorised to use the APN.
4. The 3GPP AAA Server initiates the fast re-authentication challenge.
5. The PDN GW sends an IKE_AUTH Response message to the UE, containing its identity, a certificate, and the AUTH parameter to protect the previous message it sent to the UE (in the IKE_SA_INIT exchange). It completes the negotiation of the child security associations as well. The EAP message (EAP-Request/AKA-Reauthentication) received from the 3GPP AAA Server is included in order to start the EAP procedure over IKEv2.

6. The UE checks the authentication parameters and responds to the fast re-authentication challenge. The only payload (apart from the header) in the IKEv2 message is the EAP message.
7. The PDN GW forwards the EAP-Response/AKA-Reauthentication message toward the 3GPP AAA Server.
8. When all checks are successful, the 3GPP AAA Server sends the Authentication Answer including an EAP success and the key material toward the PDN GW. This key material shall consist of the MSK generated during the fast re-authentication process. When the Wm interface (ePDG-AAA) is implemented using Diameter, the MSK shall be encapsulated in the EAP-Master-Session-Key parameter, as defined in RFC 4072 [10].

The 3GPP AAA Server steps up the counter of IKE SAs for that APN. If the maximum number of IKE SAs for that APN is exceeded, the 3GPP AAA Server shall send an indication to the PDN GW that established the oldest active IKE SA (it could be the same PDN GW or a different one) to delete the oldest established IKE SA. The 3GPP AAA Server shall update accordingly the information of IKE SAs active for the APN.

9. The MSK shall be used by the PDN GW to generate the AUTH parameters in order to authenticate the IKE_SA_INIT phase messages, as specified in RFC 4306 [3]. These two first messages had not been authenticated before as there was no key material available yet. According to RFC 4306 [3], the shared secret generated in an EAP exchange (the MSK), when used over IKEv2, shall be used to generate the AUTH parameters.
10. The EAP Success message is forwarded to the UE over IKEv2.
11. The UE shall take its own copy of the MSK as input to generate the AUTH parameter to authenticate the first IKE_SA_INIT message. The AUTH parameter is sent to the PDN GW.
12. The PDN GW checks the correctness of the AUTH received from the UE and calculates the AUTH parameter which authenticates the second IKE_SA_INIT message. The PDN GW shall send the assigned Remote IP address in the configuration payload (CFG_REPLY), if the UE requested for a Remote IP address through the CFG_REQUEST. Then the AUTH parameter is sent to the UE together with the configuration payload, security associations and the rest of the IKEv2 parameters and the IKEv2 negotiation terminates.

9.2.2.3 Security Profiles

The profiles for IKEv2 and IPsec ESP as defined in TS 33.234 [9] shall be used with the exception that ESP in transport mode shall be used.

For PDN GW certificates, the certificate profiles as defined in TS 33.234 [9] shall be used.

9.2.2.4 Enhanced Security Support

The UE and the PDN GW may support integrity protection and/or confidentiality protection of user plane traffic exchanged over the S2c tunnel when the UE is in a trusted non-3GPP access. This is achieved as follows: after the establishment of the s2c tunnel, the UE or the PDN GW may trigger the creation of a pair of IPsec child SAs as specified in RFC 4877 [2]. This may be deactivated by the UE or the PDN GW by initiating the deletion of the corresponding child SAs.

The profiles for IKEv2 and IPsec ESP in tunnel mode as defined in TS 33.234 [9] shall be used.

9.3 Network based Mobility

9.3.1 Proxy Mobile IP

9.3.1.1 Introduction

Subclause 9.3.1.2 defines the security requirements and mechanisms for Proxy Mobile IP (PMIP) when used in EPS. In particular, it addresses how PMIP messages need to be protected within the Evolved Packet Core and how PMIP protection needs to be handled if the PMIP messages originate from a trusted non-3GPP network node.

9.3.1.2 PMIP security requirements

Trust model:

- For the reference points S2a (MAG in trusted non-3GPP access network) and S2b, S5 and S8 (MAG in ePDG or Serving GW), the MAG shall be trusted by the LMA to register only those Mobile Nodes that are attached.

Requirements on mechanisms for securing PMIP messages on the reference points S2a, S2b, S5 and S8:

Security for PMIP messages between MAG and LMA shall be provided:

- either by a chain of security associations in a hop-by-hop fashion according to TS 33.210 [6]. For each hop in such a chain, one security association per direction shall be used for all PMIP messages relating to any user, or
- by one security association per direction for all PMIP messages relating to any user in an end-to-end fashion according to TS 33.210 [6] for the intra-domain case.

In order to protect PMIP messages, integrity protection is required, confidentiality protection is optional.

Strong access authentication:

- PMIP shall be used only in conjunction with AKA-based access authentication.

9.3.1.3 PMIP security mechanisms

TS 33.210 [6] shall be applied to secure PMIP messages on the reference points S2a, S2b, S5 and S8. TS 33.310 [12] may be applied regarding the use of certificates with the security mechanisms of TS 33.210 [6].

NOTE: For the case of an interface between two entities in the same security domain, TS 33.210 [6] does not mandate the protection of the interface by means of IPsec.

10 Security interworking between 3GPP access networks and non-3GPP access networks

10.1 General

The requirements and specifics for the security interworking of 3GPP access networks with different non-3GPP access networks during idle mode and active mode mobility are described in the following subclauses.

10.2 CDMA2000 Access Network

This clause captures all the security requirements for the interworking between HRPD and E-UTRAN during idle mode and active mode mobility. The present document assumes that no security context exchange is performed between E-UTRAN and HRPD access systems.

10.2.1 Idle Mode Mobility

The security interworking specifics between E-UTRAN and HRPD during idle mode mobility are defined in this clause which covers the UE idle mobility in both directions, i.e. from E-UTRAN to HRPD and HRPD to E-UTRAN.

10.2.1.1 E-UTRAN to HRPD Interworking

For pre-registration, the UE interacts directly with HRPD system to perform authentication through the HS-GW and establish security association with this system directly. The procedures are the same as in the case when the UE connects directly to the HRPD access network except that it is tunneled over the E-UTRAN/EPS. In these procedures, the UE follows the authentication and key agreement procedure described in subclause 6.2. Tunneled signaling is exchanged over S101 interface which shall be secured as described in clause 11.

NOTE: Network domain security as specified in TS 33.210 [6] and TS 33.310 [12] applies to secure signalling between eAN/PCF in the HRPD access network and MME in the serving network.

In the case when the UE is not aware of its movement from E-UTRAN to HRPD, the UE may access the HRPD system directly without performing a pre-registration through E-UTRAN/EPS system.

For UEs with an established emergency call the authentication is subject to the requirements in clause 13.

10.2.1.2 HRPD to E-UTRAN Interworking

The security interworking specifics of the UE idle mode mobility from HRPD to E-UTRAN follows the EPS network entry procedures as described in TS 33.401 [16].

10.2.2 Active mode mobility

The security interworking specifics during active mode mobility between E-UTRAN and HRPD are defined in this clause which covers the UE active mobility in both directions, i.e. from E-UTRAN to HRPD and HRPD to E-UTRAN.

10.2.2.1 E-UTRAN to HRPD Interworking

The UE behaviour is the same as in E-UTRAN-HRPD security Interworking for idle mode mobility described in subclause 10.2.1.

10.2.2.2 HRPD to E-UTRAN Interworking

The UE interacts directly with the MME to perform authentication with EPS and establish a security association with this system directly. The procedures are the same as in the case when the UE connects directly to the E-UTRAN system, except that it is tunneled over the HRPD AN. In these procedures, the UE uses EPS-AKA with the MME.

11 Network Domain Security

For all interfaces between network elements relevant in the context of the present document,

- TS 33.210 [6] shall be applied to secure signalling messages on the reference points unless specified otherwise, and
- TS 33.310 [12] may be applied regarding the use of certificates with the security mechanisms of TS 33.210 [6] unless specified otherwise in the present document.

NOTE: For the case of an interface between two entities in the same security domain, TS 33.210 [6] does not mandate the protection of the interface by means of IPsec.

12 UE-ANDSF communication security

12.1 UE-ANDSF communication security requirements

In order to address the security of communication over S14 reference point (i.e. between UE and ANDSF), the following requirements apply:

- UE and ANDSF shall be mutually authenticated;
- The UE shall be able to verify that the ANDSF is authorized to serve it.
- Signalling over S14 reference point shall be integrity protected
- Signalling over S14 reference point shall be confidentiality protected.
- Signalling over S14 reference point shall be protected against possible replay attacks.

12.2 UE-ANDSF communication security solution

UE and ANDSF server shall establish a security association to protect the messages of Access Network Info Request and Access Network Info Response. UE and ANDSF server shall mutually authenticate each other. UE and ANDSF server shall use the following mechanism to meet the security requirements as specified in clause 12.1:

For ANDSF pull messages, PSK TLS with GBA based shared key-based mutual authentication between UE and ANDSF server as specified by clause 5.4 of TS33.222 [24].

For ANDSF push messages one of the following mechanisms shall be used:

- If a PSK TLS connection has been established as a part of a pull message and is still available, the available PSK TLS session shall be used.
- Otherwise, PSK TLS with GBA push based shared key-based mutual authentication between the UE and the ANDSF server shall be used. GBA push is specified in TS 33.223 [29].

NOTE: If a TLS connection is released, it can only be re-established by the client side, i.e. UE, even though the TLS session including security association would be alive on both sides. TLS connection, in turn, is dependent on the underlying TCP connection.

The ANDSF shall request the User Security Settings (USS) from the BSF and deducts the authorization information for this UE from USS as specified in TS 29.109 [25].

For the authorization of the ANDSF server to the UE, the UE shall check that the ANDSF that the UE discovered and is connecting to is on the configured list of ANDSF names.

13 Security Aspects of Emergency Call Handling

13.1 General

NOTE: Support for EPS emergency calling is defined in the TS 23.402 [5]. Per TS 23.402 [5], this release of this specification is limited to support of handover of emergency sessions from E-UTRAN access to HRPD access only. In this release of this specification, handover of IMS Emergency Sessions from HRPD access to E-UTRAN access is not supported.

13.2 Requirements for Emergency Call handling

If the UE is authenticated in E-UTRAN and has an emergency call established and at that point attempts a hand over to HRPD, authentication and authorization of the UE to HRPD is executed according to operator policy and local regulatory requirements. If the HRPD network chooses to perform authentication and authorization at the handover and either one of them fail, then it is up to operator policy and local regulatory requirements whether the UE shall be allowed to get service from the HRPD network.

If the UE has established an unauthenticated emergency call in E-UTRAN and attempts a handover to HRPD, then it is up to local regulations and operator policy if the UE shall receive service from HRPD network. E-UTRAN provides an indication to HRPD access whether the UE has been authenticated in E-UTRAN or not, as described in TS 23.402 [5].

Annex A (normative): Key derivation functions

A.1 KDF interface and input parameter construction

All key derivations (including input parameter encoding) shall be performed using the key derivation function (KDF) specified in TS 33.220 [8]. This clause specifies how to construct the input string, S , to the KDF (which is input together with the relevant key). For each of the distinct usages of the KDF, the input parameters S are specified below.

The FC number space used is controlled by TS 33.220 [8], FC values allocated for this specification are in range of $0x20 - 0x2F$.

A.2 Function for the derivation of CK' , IK' from CK , IK

When deriving CK' , IK' from CK , IK and the access network identity as defined in clause 6 of this specification, the following parameters shall be used to form the input S to the KDF.

- $FC = 0x20$,
- $P0 =$ value of access network identity, as defined in 3GPP TS 24.302 [22],
- $L0 =$ length of value of access network identity (variable, depending on access network type),
- $P1 = SQN \oplus AK$
- $L1 =$ length of $SQN \oplus AK$ (i.e. $0x00\ 0x06$)

If AK is not used, AK shall be treated in accordance with TS 33.102, i.e. as $000\dots0$.

The access network identity is defined separately for each access network type. For each access network type, the access network identity is documented in TS 24.302 [22] to ensure that UE and HSS use the same access network identities as input for key derivation.

The input key shall be the concatenation $CK \parallel IK$ of CK and IK .

The KDF returns a 256-bit output, where the 128 most significant bits are identified with CK' and the 128 least significant bits are identified with IK' .

Annex B (informative): Change history
